Get / Build VyOS Quickly [Build](#) your own Image or take a look at how to [download](#) a free or supported version.

Install VyOS Read about how to install VyOS on [Bare Metal](#) or in a [Virtual Environment](#) and how to use an image with the usual [cloud](#) providers

Configuration and Operation Use the [Quickstart Guide](#), to have a fast overview. Or go deeper and set up [advanced routing](#), [VRFs](#), or [VPNs](#) for example.

Automate Integrate VyOS in your automation Workflow with [Ansible](#), have your own [local scripts](#), or configure VyOS with the [HTTPS-API](#).

Examples Get some inspiration from the [Configuration Blueprints](#) to build your infrastructure.

Contribute and Community

There are many ways to contribute to the project.

Add missing parts or improve the [Documentation](#).

Discuss in [Slack](#) or the [Forum](#).

Or you can pick up a [Task](#) and fix the [code](#).

VyOS is an open source network operating system based on Debian GNU/Linux.

VyOS provides a free routing platform that competes directly with other commercially available solutions from well known network providers. Because VyOS runs on standard amd64, i586 and ARM systems, it is able to be used as a router and firewall platform for cloud deployments.

We use multiple live versions of our manual, hosted thankfully by <https://readthedocs.org>. We will provide one version of the manual for every VyOS major version starting with VyOS 1.2 which will receive Long-term support (LTS).

The manual version is selected/specified by it's Git branch name. You can switch between versions of the documentation by selecting the appropriate branch on the bottom left corner.

VyOS CLI syntax may change between major (and sometimes minor) versions. Please always refer to the documentation matching your current, running installation. If a change in the CLI is required, VyOS will ship a so called migration script which will take care of adjusting the syntax. No action needs to be taken by you.

### 2.1 In the beginning...

There once was a network operating system based on Debian GNU/Linux, called Vyatta.\*<sup>0</sup> 2006 onwards, it was a great free software alternative to Cisco IOS and Juniper JUNOS. It came in two editions: Vyatta Core (previously Vyatta Community Edition) that was completely free software, and Vyatta Subscription Edition that had proprietary features and was only available to paying customers.†<sup>0</sup>

Vyatta was acquired by Brocade Communication Systems in 2012. Shortly after, Brocade renamed Vyatta Subscription Edition to Brocade vRouter, discontinued Vyatta Core and shut down the community forum without a notice. The bug tracker and Git repositories followed next year.

It's worth noting that by the time Brocade acquired Vyatta, development of Vyatta Core was already stagnated. Vyatta Subscription Edition (and thus, Vyatta development as a whole) had been replacing core components with proprietary software, meaning few features made it to Vyatta Core, and those that did were bug-ridden and hamstrung.

In 2013, soon after Vyatta Core was abandoned, the community forked the last Vyatta Core version (6.6R1) and VyOS Project came into being. [Sentrium SL](#) was established by VyOS maintainers in 2014 to fund VyOS development by selling support, consulting services and prebuilt long-term support images.

Brocade was acquired by Broadcom in 2016 and sold what remains of erstwhile Vyatta to AT&T in 2017, who in turn sold it to Ciena in 2021.

---

<sup>0</sup> From the Sanskrit adjective „Vyāṭṭa“ (), meaning opened.

<sup>0</sup> A business model comparable to that of Redis, rather than that of VyOS today.

## 2.2 Major releases

VyOS major versions used to be named after elements in order of atomic numbers. With 1.2, this naming scheme was replaced with the much cooler scheme of IAU designated constellations by solid angle area, starting from the smallest.

### 2.2.1 Hydrogen (1.0)

Released just in time for holidays on 22 December 2013, Hydrogen was the first major VyOS release. It fixed features that were broken in Vyatta Core 6.6 (such as IPv4 BGP peer groups and DHCPv6 relay) and introduced command scripting, a task scheduler and web proxy LDAP authentication.

### 2.2.2 Helium (1.1)

Helium was released on 9 October 2014, exactly on the day VyOS Project first came into being in the previous year. Helium came with a lot of new features, including an event handler and support for L2TPv3, 802.1ad QinQ and IGMP proxy, as well as experimental support for VXLAN and DMVPN (the latter of which was also broken in Vyatta Core due to its reliance on a proprietary NHRP implementation).

### 2.2.3 Crux (1.2)

Crux (the Southern Cross) came out on 28 January 2019 and was the first major release of VyOS as we know it today. The underlying Debian base was upgraded from Squeeze (6) to Jessie (8).

Although Crux came with too many new features to mention here, some noteworthy ones are: an mDNS repeater, a broadcast relay, a high-performance PPPoE server, an HFSC scheduler, as well as support for Wireguard, unicast VRRP, RPKI for BGP and fully 802.1ad-compliant QinQ ethertype. The telnet server and support for P2P filtering were removed.

Crux is the first version to feature the modular image build system. CLI definitions began to be written in the modern, verifiable XML templates. Python APIs were introduced for command scripting and configuration migration. Introduction of new Perl and shell code was proscribed and the rewriting of legacy Perl code in pure Python began with Crux.

As of 2022, Crux is still supported and maintained.

### 2.2.4 Equuleus (1.3)

The current long-term support version of VyOS, Equuleus (the Pony) came out on 21 December 2021, once again in time for the winter holidays.

Equuleus brought many long-desired features with it, most notably an SSTP VPN server, an IPoE server, an Open-Connect VPN server and a serial console server, in addition to reworked support for WWAN interfaces, support for GENEVE and MACSec interfaces, VRF, IS-IS routing, preliminary support for MPLS and LDP, and many other initialisms.

As of 2022, Equuleus is in the stable.

### 2.2.5 Sagitta (1.4)

Sagitta (the Arrow) is the codename of the current development branch, so there's no VyOS 1.4 yet.

### 2.2.6 Circinus (1.5)

Circinus (the Compass) is the codename of the upcoming development branch, so there's no VyOS 1.5 yet.

## 2.3 A note on copyright

Unlike Vyatta, VyOS never had (nor will ever have) proprietary code. The only proprietary material in VyOS is non-code assets, such as graphics and the trademark „VyOS“.<sup>0</sup> This means you can build your own long-term support images (as the entire toolchain we use is free software) and even distribute them, given you rename it and remove such assets before building. Although note that we do not provide support for images distributed by a third-party. See the [artwork license](#) and the end-user license agreement at `/usr/share/vyos/EULA` in any pre-built image for more precise information.

---

<sup>0</sup> This is not unlike how Linus Torvalds owns the trademark „Linux“.

### 3.1 1.5 Circinus

#### 3.1.1 2024-04-26

- T6259 (feature): PKI: Support RFC822 (email) names in SAN

#### 3.1.2 2024-04-25

- T6263 (bug): Multicast: Could not commit multicast config with multicast join group using source-address
- T5833 (bug): Not all AFIs compatible with VRF

#### 3.1.3 2024-04-24

- T6255 (bug): Static table description should not contain white-space
- T6226 (feature): add HAPROXY `tcp-request content accept` related block to load-balancing reverse proxy config
- T6109 (bug): remote syslog do not get all the logs
- T6262 (default): Update the boot splash for VyOS 1.5 ISO
- T6217 (feature): VRRP contrack-sync script change name of the logger
- T6244 (feature): Spacing of "Show System Uptime" hard to parse

### 3.1.4 2024-04-23

- T6260 (bug): image-tools: remove failed image directory if 'No space left on device' error
- T6261 (default): Typo in op\_mode connect\_disconnect print statement for check\_ppp\_running
- T6237 (feature): IPSec remote access VPN: ability to set EAP ID of clients

### 3.1.5 2024-04-22

- T5996 (bug): unescape backslashes for config save, compare commands

### 3.1.6 2024-04-21

- T6191 (bug): Policy Route TCP-MSS Behavior Different from 1.3.x
- T5535 (feature): disable-directed-broadcast should be moved to firewall global-options

### 3.1.7 2024-04-20

- T6252 (bug): gre tunnel - doesn't allow configure jumbo frame more than 8024

### 3.1.8 2024-04-19

- T6221 (bug): Enabling VRF breaks connectivity
- T6035 (bug): QoS policy shaper queue-type random-detect requires limit avpkt
- T6246 (feature): Enable basic haproxy http-check configuration options
- T6242 (feature): Loadbalancer reverse-proxy: SSL backend skip CA certificate verification

### 3.1.9 2024-04-17

- T6168 (bug): add system image does not set default boot to current console type in compatibility mode
- T6243 (bug): Update vyos-http-api-tools for package idna security advisory
- T6154 (enhancement): Installer should ask for password twice
- T5966 (default): Adjust dynamic dns configuration address subpath to be more intuitive and other op-mode adjustments
- T5723 (default): mdns repeater: Always reload systemd daemon before applying changes
- T5722 (bug): Failing to add route in failover if gateway not in the same interface network
- T5612 (default): Miscellaneous improvements and fixes for dynamic DNS configuration
- T5574 (default): Support per-service cache management for dynamic dns providers

### 3.1.10 2024-04-16

- [T6099](#) (bug): Suppress unsupported interfaces from appearing in messages log by Telegraf

### 3.1.11 2024-04-15

- [T6163](#) (bug): kea-dhcp4-server crashes due to incorrect lease file permissions after 1.5-rolling-202403120022 -> 1.5-rolling-202403230018 upgrade
- [T6100](#) (bug): NAT config migration error in 1.4.0-epa1 if invalid address/network defined in 1.3.6 version
- [T6174](#) (bug): can't view dhcp server leases if logged in as a tacacs account
- [T5734](#) (bug): OpenVPN server dh-params that are not in PKI error

### 3.1.12 2024-04-14

- [T6210](#) (feature): Add container ability to configure capability sys-nice

### 3.1.13 2024-04-13

- [T6173](#) (bug): Build Causes Errors When "--version" Contains Slashes ("/")
- [T2518](#) (feature): Support NAT for ipv6(NPT)

### 3.1.14 2024-04-12

- [T6214](#) (bug): Error when using some constraints
- [T6213](#) (bug): Firewall group constraints
- [T6222](#) (bug): VRRP rfc3768-compatibility not working correctly when resulting interface name is over 15 characters
- [T6218](#) (bug): Container network interface in VRF fails to generate IPv6 link-local address
- [T5044](#) (feature): High Availability in DHCPv6 -ISC DHCP Failover/Kea
- [T6166](#) (bug): Tech support generation error for custom output location
- [T344](#) (feature): Software based FastPath

### 3.1.15 2024-04-11

- [T4516](#) (feature): Rewrite system image manipulation tools in Python
- [T4548](#) (feature): GRUB loader configuration rework
- [T6228](#) (bug): Cleanup of not existing units

### 3.1.16 2024-04-10

- T6207 (bug): image-tools: restore ability to copy config.boot.default on image install
- T6106 (bug): Valid commit error for route-reflector-client option defined in peer-group
- T5750 (bug): Upgrade from 1.3.4 to 1.4 Rolling fails QoS
- T5740 (bug): Generate wireguard keys via HTTP-API fails
- T5858 (bug): Show conntrack statistics formatting is all over the place

### 3.1.17 2024-04-09

- T6121 (feature): Extend service config-sync for sections vpn, policy, vrf

### 3.1.18 2024-04-08

- T6197 (bug): IPoE-server interface client-subnet looks broken or works with the wrong logic
- T6196 (bug): Route-map and summary-only do not work in BGP aggregation at the same time
- T6068 (feature): dhcp server: allow switching between load-balanced and hotspare mode

### 3.1.19 2024-04-07

- T6205 (bug): ipoe: error in migration script logic while renaming mac-address to mac node
- T5862 (bug): Default MTU is not acceptable in some environments
- T6208 (feature): container: rename "cap-add" CLI node to "capability"
- T6188 (feature): Add Firewall Rule Description to "show firewall" commands
- T1244 (default): Support for StartupResync in conntrackd

### 3.1.20 2024-04-06

- T6203 (enhancement): Remove obsoleted xml lib
- T6202 (bug): Multi-Protocol BGP is broken by 6PE patch in upstream FRR 9.1

### 3.1.21 2024-04-05

- T6089 (bug): [1.3.6->1.4.0-epa1 Migration] "ospf passive-interface default" incorrectly added
- T2590 (bug): DHCPv6 not updating nameservers and search domains since replacing isc-dhcp-client with WIDE dhcp6c
- T6199 (feature): spring cleaning - drop unused Python imports

### 3.1.22 2024-04-04

- T6119 (default): Use a compliant TOML parser
- T6171 (feature): dhcp server fail-over - Rename fail-over node
- T6128 (bug): minisign.pub is wrong on <https://vyos.net/get/nightly-builds/>
- T5882 (feature): vyos-utils: move to Dune as build system
- T5864 (default): 'show ntp' Commands Not Working
- T3843 (bug): l2tp configuration not cleared after delete
- T2187 (feature): Python Unit testing
- T788 (bug): Nightly builds are not signed

### 3.1.23 2024-04-03

- T6198 (feature): configverify: add common helper for PKI certificate validation
- T6192 (feature): Multi VRF support for SSH

### 3.1.24 2024-04-02

- T6167 (bug): VNI not set on VRF after reboot
- T6151 (default): BGP VRF - Route-leaking not work when the next-hop is a recursive route.
- T6033 (bug): hsflowd fails to start when using a tunnel interface

### 3.1.25 2024-04-01

- T6195 (feature): dropbear: package upgrade 2022.83-1 -> 2022.83-1+deb12u1
- T6193 (bug): dhcp-client: invalid warning "is not a DHCP interface but uses DHCP name-server option" for VLAN interfaces
- T6178 (bug): Reverse-proxy should check that certificate exists during commit

### 3.1.26 2024-03-31

- T6186 (bug): Fix regression in 'set system image default-boot'
- T5832 (feature): Keepalived: Allow using the 'dev' statement on excluded-addresses

### 3.1.27 2024-03-29

- T6159 (bug): Openvpn Server Op-cmd adds heading "OpenVPN status on vtunx" for every client connection

### 3.1.28 2024-03-28

- T6147 (bug): Conntrack not working as expected with global state-policy
- T6175 (bug): op-mode: "renew dhcp interface <name>" does not check if it's an actual DHCP interface
- T6102 (bug): Clear dhcp-server lease throws python exception on 1.5-rolling

### 3.1.29 2024-03-26

- T6066 (bug): Setting same network in different ospf area will raise exception

### 3.1.30 2024-03-25

- T6145 (bug): Service config-sync does not rely on priorities but must

### 3.1.31 2024-03-24

- T6161 (feature): Output container images as JSON
- T6165 (bug): grub: vyos-grub-update failed to start on "slow" systems
- T6085 (bug): VTI interfaces are in UP state by default
- T6152 (bug): Kernel panic for ZimaBoard 232

### 3.1.32 2024-03-23

- T6160 (bug): isis: NameError: name 'process' is not defined
- T6131 (bug): Disabling openvpn interface(s) causes OSPF to fail to load on reboot
- T4022 (feature): Add package nat-rtsp-dkms

### 3.1.33 2024-03-22

- T6136 (bug): Configuring a dynamic address group, config script did not check whether the group was created
- T6130 (bug): [1.3.6->1.4.0-epa2 Migration] BGP "set community" missing
- T6090 (bug): [1.3.6->1.4.0-epa1 Migration] policy route fails due tcp flag case sensitivity
- T6155 (default): ixgbe: failed to initialize because an unsupported SFP+ module type was detected.
- T6125 (feature): Support 802.1ad (0x88a8) vlan filtering for bridge

### 3.1.34 2024-03-21

- T6143 (feature): Increase configuration timeout range for service config-sync

### 3.1.35 2024-03-20

- T6133 (feature): Add domain-name to commit-archive
- T6129 (feature): bgp: add route-map option "as-path exclude all"

### 3.1.36 2024-03-19

- T6127 (bug): Ability to view logs for rules with Offload not functional
- T6138 (bug): Conntrack table op-mode fails with flowtable offload entries

### 3.1.37 2024-03-15

- T6118 (feature): radvd: RFC8781: add nat64prefix support

### 3.1.38 2024-03-12

- T6020 (bug): VRRP health-check script is not applied correctly in keepalived.conf
- T5646 (bug): QoS policy limiter broken if class without match

### 3.1.39 2024-03-11

- T6098 (bug): Description doesnt seem to allow for non international characters
- T2998 (bug): SNMP v3 oid "exclude" option doesn't work
- T6107 (bug): Nginx does not allow big config queries for configure endpoint API
- T6096 (bug): Config commits are not synced properly because 00vyos-sync is deleted by vyos-router
- T6093 (bug): Incorrect dhcp-options vendor-class-id regex
- T6083 (feature): ethtool: move string parsing to JSON parsing

- T6069 (bug): HTTP API segfault during concurrent configuration requests
- T6057 (feature): Add ability to disable syslog for conntrackd
- T5504 (feature): Keepalived VRRP ability to set more than one peer-address
- T5717 (feature): ospfv3 - add allow to set metric-type to ospf redistribution while frr docs says its possible.
- T6071 (bug): firewall: CLI description limit of 256 characters cause config upgrade issues

### 3.1.40 2024-03-08

- T6086 (bug): NAT does not work with network-groups
- T6094 (bug): Destination Nat not Making Firewall Rules
- T6061 (bug): connection-status nat destination firewall filter not working in 1.4.0-epal
- T6075 (bug): Applying firewall rules with a non-existent interface group

### 3.1.41 2024-03-07

- T6104 (bug): Regression in commit-archive for non-interactive configuration
- T6084 (bug): OpenNHRP DMVPN configuration file clean after reboot if we have any IPSec configuration
- T5348 (bug): Service config-sync can freeze the secondary router if it has commit-archive location
- T6073 (bug): Conntrack/NAT not being disabled when VRFs are defined
- T6095 (default): Tab completion for "set interfaces wireless wlan0 country-code" incorrect country "uk"

### 3.1.42 2024-03-06

- T6079 (bug): dhcp: migration fails for duplicate static-mapping
- T6063 (default): Kea DHCP: Expose match-client-id setting
- T5992 (default): DHCP: show dhcp server leases not showing all leases

### 3.1.43 2024-03-05

- T5903 (bug): NHRP don't start on reboot from version 1.5-rolling-202401010026
- T2447 (feature): Additional Boot Argument Configuration to limit CPU C-States

### 3.1.44 2024-03-04

- T6087 (feature): ospfv3: add support to redistribute IS-IS routes

### 3.1.45 2024-03-02

- T6081 (bug): QoS policy shaper target and interval wrong calculations

### 3.1.46 2024-02-29

- T6078 (feature): Update ethtool to 6.6
- T6077 (feature): banner: implement ASCII contest winner default logo
- T6074 (feature): container: do not allow deleting images which have a container running

### 3.1.47 2024-02-28

- T4270 (bug): dns forwarding - When "ignore-hosts-file" is unset, local hostname of router resolves to 127.0.1.1

### 3.1.48 2024-02-26

- T6064 (bug): Can not build VyOS if repository is not cloned to a branch
- T5754 (default): Update to StrongSwan 5.9.11

### 3.1.49 2024-02-25

- T6060 (feature): op-mode: container: support removing all container images at once

### 3.1.50 2024-02-24

- T5909 (bug): Container registry with authentication prevents config load (section container) after reboot

### 3.1.51 2024-02-23

- T5376 (bug): Conntrack FTP helper does not work properly

### 3.1.52 2024-02-22

- T6048 (bug): Exception in event handler script

### 3.1.53 2024-02-21

- T6050 (bug): Wrong scripting commands descriptions in accel-ppp services
- T3771 (feature): DHCPv6 server prefix delegation - dynamically add route to delegated prefix via requesting router

### 3.1.54 2024-02-19

- T5971 (default): Create the same view of ppp section for all accel-ppp services
- T6029 (default): Rewrite Accel-PPP services to an identical feature set
- T3722 (bug): op-mode IPsec show vpn ike sa always shows L-TIME 0

### 3.1.55 2024-02-18

- T6043 (bug): VxLAN and bridge error bug
- T6041 (bug): image-tools: install fails from PXE boot into live iso due to restrictive logic

### 3.1.56 2024-02-17

- T5972 (feature): login: add possibility to disable individual local user accounts

### 3.1.57 2024-02-16

- T6009 (bug): Firewall - Time not working properly when not using UTC
- T6005 (bug): Error on adding a wireguard interface to OSPFv3
- T6019 (feature): Bump nftables and libnftnl version
- T6001 (default): Add option to enable resolve-via-default
- T5965 (bug): WWAN modems using raw-ip do not work with dhclient/dhcp6c
- T5245 (bug): Wireless interfaces do not get IPv6 link-local address assigned

### 3.1.58 2024-02-15

- T5977 (bug): nftables: Operation not supported when using match-ipsec in outbound firewall
- T2612 (bug): HTTPS API, changing API key fails but goes through
- T5989 (bug): IP subnets not usable in UPnP ACLs
- T5719 (default): mdns repeater: Add op-mode commands
- T4839 (feature): Dynamic Firewall groups

### 3.1.59 2024-02-14

- T6034 (feature): rpki: move file based SSH keys for authentication to PKI subsystem
- T5981 (bug): IPsec site-to-site migrated PKI ca certificates are created with an '@'
- T5930 (bug): vrf - route-leak not work using route-target both command.
- T5709 (bug): IPoE-server fails if next pool mentioned but not defined
- T2044 (bug): RPKI doesn't boot properly
- T6032 (feature): bgp: add EVPN MAC-VRF Site-of-Origin support
- T5960 (default): Rewriting authentication section in accel-ppp services

### 3.1.60 2024-02-13

- T5928 (bug): Configuration fails to load on boot if offloading has VLAN interfaces defined
- T5064 (bug): Value validation for domain-groups seems to be broken

### 3.1.61 2024-02-12

- T6010 (bug): Support setting multiple values in BGP path-attribute
- T6004 (bug): RPKI is not configured
- T5952 (default): DHCP allow same MAC Address on same subnet
- T5849 (feature): Add SRv6 route commands

### 3.1.62 2024-02-10

- T6023 (bug): rpki: add support for CLI knobs expire-interval and retry-interval

### 3.1.63 2024-02-09

- T6028 (bug): QoS policy shaper wrong class\_id\_max and default\_minor\_id
- T6026 (bug): QoS hide attempts to delete qdisc from devices
- T5788 (feature): frr: update to 9.1 release
- T5703 (bug): QoS config on pppoe interface resets back to fq\_codel after tunnel reboots
- T5685 (feature): Keepalived VRRP prefix is not necessary for the virtual address

### 3.1.64 2024-02-08

- T6014 (feature): Bump keepalived version
- T5910 (bug): Grub problem(?) Serial Console no longer working
- T6021 (bug): QoS r2q wrong calculation

### 3.1.65 2024-02-07

- T6017 (bug): Update vyos-http-api-tools for security advisory
- T6016 (bug): Resolve intermittent failures in cleanup function after failed image install
- T6024 (feature): bgp: add additional missing FRR features
- T6011 (feature): rpki: known-hosts-file is no longer supported by FRR CLI - remove VyOS CLI node
- T5998 (feature): replay\_window setting under vpn in config

### 3.1.66 2024-02-06

- T6018 (default): smoketest: updating http-api framework requires a pause before test
- T5921 (bug): Trying to commit an OpenConnect configuration without any local users results in an exception
- T5687 (feature): Implement ECS settings for PowerDNS recursor

### 3.1.67 2024-02-05

- T5974 (bug): QoS policy shaper is currently miscalculating bandwidth and ceil values for the default class
- T5865 (feature): Rewrite ipv6 pool section to ipv6 named pools in Accel-ppp services

### 3.1.68 2024-02-02

- T5739 (bug): Password recovery does not work if public keys are configured
- T5955 (feature): Rootless containers/set uid/gid for container
- T6003 (feature): Add 'show rpki as-number' and 'show rpki prefix'
- T5848 (feature): Add triple-isolate flow isolation option to CAKE QoS policy

### 3.1.69 2024-02-01

- T5995 (bug): Kernel NIC-drivers for Huawei NICs are not properly enabled
- T5978 (bug): ethernet: hw-tc-offload does not actually get enabled on the NIC
- T5979 (enhancement): Add configurable kernel boot parameters
- T5973 (bug): vrf: RTNETLINK answers: File exists
- T5967 (bug): Multi-hop BFD connections can't be established; please add minimum-ttl option.
- T5619 (default): Update the Intel ixgbe driver due to issues with Intel X533

### 3.1.70 2024-01-31

- T6000 (bug): [1.3.x -> 1.5.x] migrating threw exception in /opt/vyatta/etc/config-migrate/migrate/https/5-to-6, performed workaround
- T5999 (bug): load-balancing reverse-proxy can't configure root as a redirect

### 3.1.71 2024-01-30

- T5980 (feature): Add image-tools support for configurable kernel boot options

### 3.1.72 2024-01-29

- T5988 (bug): image-tools: a check of valid image name is missing from 'add image'
- T5994 (bug): Fix typo in 'remote' module preventing 'add system image' via ftp

### 3.1.73 2024-01-26

- T5957 (bug): Firewall fails to delete inbound-interface name
- T5779 (bug): custom conntrack timeout rule not applicable
- T5984 (feature): Add user util numactl

### 3.1.74 2024-01-25

- T5983 (bug): image-tools: minor regression in pruning version files in compatibility mode
- T5927 (bug): QoS policy shaper-hfsc class does not have a `bandwidth` node but requires one in the check
- T5834 (bug): Rename 'enable-default-log' to 'default-log'

### 3.1.75 2024-01-22

- T5968 (feature): hsflowd: add VRF support
- T5961 (bug): QoS policy shaper vif with ceiling fails on commit
- T5958 (bug): QoS policy shaper-hfsc is not implemented
- T5969 (feature): op-mode: list multicast group membership

### 3.1.76 2024-01-21

- T5799 (bug): vyos unbootable after 1.4-rolling-202308240020 to 1.5-rolling-202312010026 upgrade
- T5787 (bug): dhcp-server allows duplicate static-mapping for the same IP address
- T5912 (bug): DHCP Static mapping don't work on every first lease
- T5692 (enhancement): NTP leap smear
- T5954 (feature): Enable nvme\_hwmon and drivetemp in KERNEL

### 3.1.77 2024-01-20

- T5964 (bug): disconnect interface wwan0 throws exception
- T5948 (bug): pdns-recursor crashes on restart if hostfile-update is enabled and dhcp client sends hostname with trailing dot
- T5945 (bug): Missing minisign public key for rolling release
- T5922 (bug): Firewall - bug in zone config
- T5915 (bug): Firewall zone - Re add op-mode commands
- T5724 (feature): About dhcp client hooks
- T5721 (bug): Error in migrating configuration from VyOS 1.4
- T5550 (bug): Source validation on interface does not work properly
- T5239 (bug): frr 'hostname' missing or incorrect, and domain-name missing totally
- T4726 (default): Add completion and validation for the accel-ppp RADIUS vendor option
- T4085 (feature): Rewrite L2TP/PPTP/SSTP/PPPoE services to get\_config\_dict
- T5963 (bug): QoS policy shaper rate calculations could be wrong for some ethernet devices
- T5876 (bug): Dhcp bug in latest 1.5 rolling releases

- T5962 (feature): QoS policy set default speed to 100mbit or 1gbit instead of 10mbit

### 3.1.78 2024-01-19

- T5897 (bug): VyOS with Cloud-init and VRF stuck at reboot/shutdown process
- T5554 (bug): Disable sudo for PAM RADIUS
- T4754 (default): Improvement: system login: show configured 2FA OTP key
- T5857 (bug): show interfaces wireless info
- T5841 (default): Remove old ssh-session-cleanup.service
- T5884 (default): Minor description fix (op-mode: generate wireguard)
- T5781 (default): Add ability to add additional minisign keys

### 3.1.79 2024-01-18

- T5863 (bug): Failure to Load Config on Recent 1.5 Versions
- T4638 (bug): Deleting a parent interface does not delete its underlying VLAN interfaces
- T5953 (default): Rename 'close\_action' value from 'hold' to 'trap' in IPSEC IKE

### 3.1.80 2024-01-17

- T5923 (bug): Config mode system\_console.py is not aware of revised GRUB file structure
- T4658 (feature): Rename DPD action 'hold' to 'trap'

### 3.1.81 2024-01-16

- T5859 (bug): Invalid format of pool range in accel-ppp services
- T5842 (feature): Rewrite PPTP service to get\_config\_dict
- T5801 (feature): Rewrite L2TP service to get\_config\_dict
- T5688 (default): Create the same view of pool configuration for all accel-ppp services

### 3.1.82 2024-01-15

- T5944 (bug): "reboot in 1" not working
- T5936 (bug): [1.3.5 -> 1.4.0-RC1 Migration] OSPF Passive Interface Configuration Not Working Correctly
- T5247 (bug): the bug of the command "show interfaces system"
- T5901 (bug): Cloud-init and DHCP exit hook errors
- T2556 (bug): "show interfaces vrrp" does not return any interface

### 3.1.83 2024-01-12

- T5925 (feature): Containers change systemd KillMode
- T5919 (bug): Firewall - opmode for ipv6
- T5306 (default): bgp config migration failed with v6only option configured with peer-group
- T3429 (bug): Hyper-V integration services not working on VyOS 1.4 (sagitta/current)

### 3.1.84 2024-01-11

- T5713 (bug): strip-private doesn't strip string after "secret"
- T5532 (bug): After add system image the boot stuck and works again after the second reboot
- T5814 (bug): VyOS 1.3 to 1.4 LTS Firewall ruleset migration script breaks configuration
- T3191 (bug): PAM RADIUS freezing when accounting does not configured on RADIUS server
- T5917 (feature): Restore annotations of (running)/(default boot) in select image list
- T5916 (default): Added segment routing check for index size and SRGB size
- T5913 (feature): Allow for Peer-Groups in ipv4-labeled-unicast SAFI

### 3.1.85 2024-01-10

- T5918 (bug): Verification problem for `set vpn ipsec interface`
- T5911 (bug): pki: service update ignored if certificate name contains a hyphen (-)
- T5886 (feature): Add support for ACME protocol (LetsEncrypt)
- T5766 (bug): http: rewrite conf-mode script to get\_config\_dict()
- T4256 (feature): Display static DHCP server leases in the operational command output
- T5902 (bug): http: remove virtual-host configuration in webserver
- T3316 (feature): Use Kea DHCP(v6) instead of ISC DHCP(v6)
- T5791 (default): Update dynamic dns configuration path to be consistent with other areas of VyOS
- T5708 (default): Additional dynamic dns improvements to align with ddclient 3.11.1 release
- T5573 (bug): Fix ddclient cache entries
- T5614 (default): Add conntrack helper matching on firewall

### 3.1.86 2024-01-09

- T5898 (bug): Replace partprobe with partx due to unable to install VyOS
- T5840 (feature): Upgrade Kea to 2.4.x
- T5838 (feature): Add Infiniband kernel modules
- T5785 (bug): API output of show container image broken
- T5249 (feature): Add rollback-soft feature to rollback without a reboot
- T2511 (feature): Migrate vyatta-op-quagga to new XML format
- T5905 (bug): pki: IPsec and VTI interface priority inversion when using x509 site-to-site peer

### 3.1.87 2024-01-08

- T5888 (bug): Firewall upgrade fails because of icmpv6
- T5844 (bug): HTTPS API doesn't start without configured keys even when GraphQL authentication type is set to token
- T5904 (feature): op-mode: add "show ipv6 route vrf <name> <prefix>" command

### 3.1.88 2024-01-07

- T5899 (feature): VyOS vm images use bookworm repo
- T5887 (feature): Upgrade Linux Kernel to 6.6.y (2023 LTS edition)

### 3.1.89 2024-01-06

- T3214 (bug): OpenVPN IPv6 fixes

### 3.1.90 2024-01-05

- T5894 (feature): Extend get\_config\_dict() with additional parameter with\_pki that defaults to False

### 3.1.91 2024-01-03

- T5880 (bug): verify\_source\_interface should not allow dynamic interfaces like ppp, l2tp, ipoe or sstpc client interfaces
- T5879 (bug): tunnel: sourceing from dynamic pppoe0 interface will fail on reboots

### 3.1.92 2024-01-02

- T5885 (default): image-tools: relax restriction on image-name length from 32 to 64

### 3.1.93 2024-01-01

- T5883 (bug): Preserve file ownership in /config subdirs on add system image
- T5474 (feature): Establish common file name pattern for XML conf mode commands

### 3.1.94 2023-12-30

- T5875 (bug): login: removing and re-adding a user keeps the home directory but UID will change, thus SSH keys no longer work
- T5653 (feature): Command to display fingerprint

### 3.1.95 2023-12-29

- T5829 (bug): Can't Add IPv6 Address to Containers
- T5852 (bug): Reboots fail with eapol WAN interface
- T5869 (bug): vyos.template.first\_host\_address() does not honor RFC4291 section 2.6.1

### 3.1.96 2023-12-28

- T5827 (bug): image-tools: 'show system image' Command Not in Order
- T4163 (feature): [BMP-BGP] Routing monitoring feature
- T5867 (feature): Upgrade podman to Debian Trixie version 4.7.x
- T5866 (feature): Add op-mode command to restart IPv6 RA daemon
- T5861 (bug): Flavor build system fails with third-party packages
- T5854 (feature): Extend override-default script to allow embedded defaultValue settings
- T5792 (default): Upgrade ddclient 3.11.2 release

### 3.1.97 2023-12-25

- T5855 (feature): Migrate "set service lldp snmp enable" -> `set service lldp snmp`
- T5837 (bug): vyos.configdict.node\_changed does not return keys per adding
- T5856 (bug): SNMP service removal fails

### 3.1.98 2023-12-23

- T5678 (feature): Improvements in PPPoE configuration

### 3.1.99 2023-12-22

- T5804 (bug): SNAT "any" interface error

### 3.1.100 2023-12-21

- T5807 (bug): NAT66 op-mode bugs
- T5778 (bug): The show dhcp server leases operation mode command does not work as expected
- T5775 (default): Migrated Firewall Global State Policy ineffective on latest firewall zone config
- T5676 (bug): NAT66 source rule with negation source/destination prefix causes TypeError
- T5637 (bug): Firewall default-action log
- T5796 (bug): Openconnect - HTTPS security headers are missing

### 3.1.101 2023-12-20

- T5823 (feature): Protocol BGP add default values for config dictionary
- T5798 (enhancement): reverse-proxy load-balancing service should support multiple certificates for frontend

### 3.1.102 2023-12-19

- T5828 (default): Fix GRUB installation on arm64

### 3.1.103 2023-12-18

- T5751 (feature): Adjust new image tools for non-interactive use
- T5831 (feature): show system image should reverse order by addition date
- T5825 (bug): image-tools: restore authentication on 'add system image'
- T5821 (bug): image-tools: restore vrf-aware 'add system image'
- T5819 (bug): Don't echo password on install image
- T5806 (bug): Clear old raid data on new install image
- T5789 (bug): image-tools should copy ssh host keys on image update
- T5758 (default): Restore scanning configs when live installing

### 3.1.104 2023-12-15

- T5824 (bug): busybox cannot connect some websites from initramfs
- T5770 (bug): MACsec not encrypting
- T5803 (default): git/github: Adjust configuration for safe and baseline defaults

### 3.1.105 2023-12-14

- T5773 (bug): Unable to load config via HTTP
- T5816 (bug): BGP Large Community List Validation Broken
- T5812 (bug): rollback check max revision number does not work
- T5749 (feature): Show MAC address VRF and MTU by default for "show interfaces"
- T5774 (bug): commit-archive to FTP server broken after update (VyOS 1.5-rolling)
- T5826 (default): Add dmicode as an explicit dependency
- T5793 (default): mdns-repeater: Cleanup avahi-daemon configuration in /etc

### 3.1.106 2023-12-13

- T591 (feature): Support SRv6

### 3.1.107 2023-12-12

- T5815 (enhancement): Add load\_config module

### 3.1.108 2023-12-11

- T5741 (bug): WAN Load Balancing failover route tables aren't created

### 3.1.109 2023-12-10

- T5658 (default): Add VRF support for mtr

### 3.1.110 2023-12-09

- T5808 (bug): op-mode: ipv6 ospfv3 graceful-restart description contains incorrect info
- T5802 (bug): ping (ip or hostname) interface <tab> produces error
- T5747 (feature): op-mode add MAC VRF and MTU for show interfaces summary
- T3983 (bug): show pki certificate Doesn't show x509 certificates

### 3.1.111 2023-12-08

- [T5782](#) (enhancement): Use a single config mode script for https and http-api
- [T5768](#) (enhancement): Remove auxiliary http-api.conf for simplification of http-api config mode script

### 3.1.112 2023-12-04

- [T5769](#) (bug): VTI tunnels lose their v6 Link Local addresses when set down/up

### 3.1.113 2023-12-03

- [T5753](#) (feature): Add VXLAN vnifilter support
- [T5759](#) (feature): Change VXLAN default MTU to 1500 bytes

### 3.1.114 2023-11-27

- [T5763](#) (bug): Fix imprecise check for remote file name in vyos-load-config.py
- [T5783](#) (feature): frr: smoketests must notice any daemon crash

### 3.1.115 2023-11-26

- [T5760](#) (feature): DHCP client custom dhcp-options
- [T2405](#) (feature): archive to GIT or other platform

### 3.1.116 2023-11-25

- [T5655](#) (bug): commit-archive: Ctrl+C should not error out with stack trace, signal should be caught

### 3.1.117 2023-11-24

- [T5776](#) (feature): Enable VFIO support
- [T5402](#) (bug): VRRP router with rfc3768-compatibility sends multiple ARP replies

### 3.1.118 2023-11-23

- [T5659](#) (bug): VPP cannot add interface to dataplane if it already has an address configured

### 3.1.119 2023-11-22

- T5767 (feature): Add reboot and poweroff the system via API
- T5729 (bug): Firewall, nat and policy route - Switch to valueless
- T5681 (feature): Interface match - Simplified and unified cli
- T5643 (feature): NAT - Allow interface groups on nat rules
- T5616 (feature): Firewall mark - Add capabilities for matching firewall mark
- T5590 (default): Firewall "log enable" logs every packet

### 3.1.120 2023-11-21

- T5762 (bug): http: api: smoketests fail as they can not establish IPv6 connection to uvicorn backend server

### 3.1.121 2023-11-18

- T1354 (feature): Add support for VLAN-Aware bridges

### 3.1.122 2023-11-16

- T5726 (bug): HTTPS API image cannot be updated
- T5738 (feature): Extend XML building blocks
- T5736 (feature): igmp: migrate "protocols igmp" to "protocols pim"
- T5733 (feature): pim(6): rewrite FRR PIM daemon configuration to get\_config\_dict() and add missing IGMP features
- T5689 (default): FRR 9.0.1 in VyOS current segfaults on show rpki prefix \$prefix
- T5595 (feature): Multicast - PIM bfd feature enable

### 3.1.123 2023-11-15

- T5695 (feature): Build FRR with LUA scripts --enable-scripting option
- T5677 (bug): show lldp neighbors generates TypeError when neighbor has no `descr`
- T5728 (bug): Improve compatibility between OpenVPN on VyOS 1.5 and OpenVPN Connect Client
- T5732 (bug): generate firewall rule-resequence drops geoip country-code from output
- T5661 (enhancement): Add show show ssh dynamic-protection attacker and show log ssh dynamic-protection

### 3.1.124 2023-11-13

- T5698 (feature): EVPN ESI Multihoming
- T5563 (bug): container: Container environment variable cannot be set
- T5706 (bug): Systemd-udevd high CPU utilization for multiple dynamic ppp/l2tp/ipoe interfaces

### 3.1.125 2023-11-10

- T5727 (bug): validator: Use native URL validator instead of regex-based validator

### 3.1.126 2023-11-08

- T5720 (bug): PPPoE-server adding new interface does not work
- T5716 (bug): PPPoE-server shaper template bug down-limiter option does not rely on fwmark
- T5702 (feature): Add ability to set include\_ifmib\_iface\_prefix and ifmib\_max\_num\_ifaces for SNMP
- T5693 (feature): Adding variable vyos\_persistence\_dir (and improve variable vyos\_rootfs\_dir)
- T5648 (bug): ldpd neighbour template errors
- T5564 (bug): Both show firewall group and show firewall summary fails
- T5559 (feature): Selective proxy-arp/proxy-ndp when doing SNAT/DNAT
- T5541 (bug): Zone-Based Firewalling in VyOS Sagitta 1.4

### 3.1.127 2023-11-07

- T5586 (feature): Disable by default SNMP for Keepalived VRRP

### 3.1.128 2023-11-06

- T5705 (bug): rsyslog - Not working when using facility=all
- T5704 (feature): PPPoE-server add max-starting option
- T5707 (bug): Wireguard peer public key update leaves redundant peers and breaks connectivity

### 3.1.129 2023-11-03

- T5700 (bug): Monitoring telegraf deprecated plugins inputs outputs

### 3.1.130 2023-11-02

- T5701 (feature): Update telegraf package

### 3.1.131 2023-11-01

- T5690 (bug): Change to definition of environment variable 'vyos\_rootfs\_dir' is incorrect

### 3.1.132 2023-10-31

- T5699 (feature): vxlan: migrate "external" CLI know to "parameters external"
- T5668 (feature): Disable VXLAN bridge learning and enable neigh\_suppress when using EVPN

### 3.1.133 2023-10-27

- T5663 (bug): pmacct package contains unwanted data
- T5652 (bug): Config migrate to image upgrade does not properly generate home directory

### 3.1.134 2023-10-26

- T5683 (bug): reverse-proxy pki filenames mismatch
- T5600 (bug): Firewall - Remove or extend constraint on 'interface-name'
- T5598 (bug): unknown parameter 'nf\_conntrack\_helper' ignored
- T5571 (bug): Firewall does not delete networks from the table raw
- T4903 (bug): conntrack ignore does not support IPv6 addresses
- T4309 (feature): Support network/address-groups and ipv6-network/ipv6-address-groups in conntrack ignore
- T5594 (bug): VRRP - Error if using IPv6 Link Local as hello source address
- T5606 (feature): IPSec VPN: Allow multiple CAs certificates
- T5568 (default): Install image from live ISO always defaults boot to KVM entry
- T5558 (default): Update config test to check resulting migrations

### 3.1.135 2023-10-23

- T5299 (bug): QoS shaper ceiling does not work
- T5667 (feature): BGP label-unicast - enable ecmp

### 3.1.136 2023-10-22

- T5254 (bug): Modification of any interface setting sets MTU back to default when MTU has been inherited from a bond
- T5671 (feature): vxlan: change port to IANA assigned default port

### 3.1.137 2023-10-21

- T5670 (bug): bridge: missing member interface validator
- T5617 (feature): Add an option to exclude single values to the numeric validator

### 3.1.138 2023-10-20

- T5233 (bug): Op-mode flow-accounting netflow with disable-imt errors
- T5232 (bug): Flow-accounting uacctd.service cannot restart correctly

### 3.1.139 2023-10-19

- T4913 (default): Rewrite the wireless op mode in the new style

### 3.1.140 2023-10-18

- T5642 (bug): op cmd: generate tech-support archive: does not work
- T5521 (bug): Home owner directory changed to vyos for the user after reboot

### 3.1.141 2023-10-17

- T5662 (bug): Fix indexing error in configdep script organization
- T5644 (bug): Firewall groups deletion can break config

### 3.1.142 2023-10-16

- T5165 (feature): Policy local-route ability set protocol and port

### 3.1.143 2023-10-14

- T5629 (bug): Policy local-route bug after migration to destination node address

### 3.1.144 2023-10-12

- T5649 (bug): vyos-1x should generate XML cache after building command templates for less cryptic error on typo

### 3.1.145 2023-10-10

- T5589 (bug): Nonstripped binaries exists in VyOS
- T5489 (feature): Change to BBR as TCP congestion control, or at least make it an config option

### 3.1.146 2023-10-08

- T5630 (feature): pppoe: allow to specify MRU in addition to already configurable MTU

### 3.1.147 2023-10-06

- T5576 (feature): Add bgp remove-private-as all option

### 3.1.148 2023-10-05

- T4320 (default): Remove legacy version files in vyatta-cfg-system/cfg-version

### 3.1.149 2023-10-04

- T5632 (feature): Add jq package to parse JSON files
- T3655 (bug): NAT Problem with VRF
- T5585 (bug): Fix file access mode for dynamic dns configuration

### 3.1.150 2023-10-03

- T5618 (bug): Flow-accounting crushes when IMT is enabled
- T5579 (bug): Log firewall - Wrong command after firewall refactor
- T5561 (feature): NAT - Inbound or outbound interface should not be mandatory
- T5626 (feature): Only select required Kernel CGROUP controllers
- T5628 (feature): op-mode: login: DeprecationWarning: 'spwd'

### 3.1.151 2023-09-28

- T5596 (feature): bgp: add new features from FRR 9
- T5412 (feature): Add support for extending config-mode dependencies in supplemental package

### 3.1.152 2023-09-24

- T5604 (bug): List of debian archives is out of date (non-free-firmware is missing)
- T5591 (feature): Cleanup of FRR daemons-file and various FRR fixes

### 3.1.153 2023-09-22

- T5602 (feature): For reverse-proxy type of load-balancing feature, support "backup" option in backends configuration
- T5609 (enhancement): Add util to get drive device name from id
- T5608 (enhancement): Rewrite add/delete raid member to Python and remove from vyatta-op
- T5607 (bug): Adjust RAID smoketest for non-deterministic SCSI device probing

### 3.1.154 2023-09-20

- T5588 (bug): Add kernel conntrack\_bridge module
- T5241 (feature): Support veth interfaces to working with netns
- T5592 (feature): salt: upgrade minion to 3005.2

### 3.1.155 2023-09-19

- T5597 (feature): isis: add new features from FRR 9.

### 3.1.156 2023-09-18

- T5575 (bug): ARP/NDP table-size isnt set properly

### 3.1.157 2023-09-15

- T5587 (bug): Firwall can not pass the smoketest
- T5581 (feature): Add "show ip nht" op-mode command (IPv4 nexthop tracking table)

### 3.1.158 2023-09-11

- T5562 (bug): Smoketests fail for vyos:current (test\_netns.py)
- T5551 (bug): Missing check for boot\_configuration\_complete raises error in vyos-save-config.py
- T5353 (bug): config-mgmt: normalize archive updates and commit log entries

### 3.1.159 2023-09-10

- T5555 (bug): Fix timezone migrator (system 13-to-14)

### 3.1.160 2023-09-09

- T5423 (bug): ipsec: no output for op-cmd "show vpn ike secrets"

### 3.1.161 2023-09-08

- T5560 (bug): VyOS version in current branch should be changed from 1.4 to 1.5

### 3.1.162 2023-09-07

- T5556 (bug): reboot now and poweroff does not work

### 3.1.163 2023-09-06

- T5548 (bug): HAProxy renders timeouts incorrectly

## 3.2 1.4 Sagitta

### 3.2.1 2024-04-25

- T6263 (bug): Multicast: Could not commit multicast config with multicast join group using source-address
- T5833 (bug): Not all AFIs compatible with VRF

### 3.2.2 2024-04-24

- T6255 (bug): Static table description should not contain white-space
- T6226 (feature): add HAPROXY `tcp-request content accept` related block to load-balancing reverse proxy config
- T6109 (bug): remote syslog do not get all the logs
- T6217 (feature): VRRP contrack-sync script change name of the logger
- T6244 (feature): Spacing of "Show System Uptime" hard to parse

### 3.2.3 2024-04-23

- [T6260](#) (bug): image-tools: remove failed image directory if 'No space left on device' error
- [T6261](#) (default): Typo in op\_mode connect\_disconnect print statement for check\_ppp\_running
- [T6237](#) (feature): IPSec remote access VPN: ability to set EAP ID of clients

### 3.2.4 2024-04-22

- [T5996](#) (bug): unescape backslashes for config save, compare commands
- [T6103](#) (bug): DHCP-server bootfile-name double slash syntax weird behaviour
- [T6080](#) (default): Default NTP server settings
- [T5986](#) (bug): Container: Error on commit when environment variable value contains \n line break

### 3.2.5 2024-04-21

- [T6191](#) (bug): Policy Route TCP-MSS Behavior Different from 1.3.x
- [T5535](#) (feature): disable-directed-broadcast should be moved to firewall global-options

### 3.2.6 2024-04-20

- [T6252](#) (bug): gre tunnel - doesn't allow configure jumbo frame more than 8024

### 3.2.7 2024-04-19

- [T6221](#) (bug): Enabling VRF breaks connectivity
- [T6035](#) (bug): QoS policy shaper queue-type random-detect requires limit avpkt
- [T6246](#) (feature): Enable basic haproxy http-check configuration options
- [T6242](#) (feature): Loadbalancer reverse-proxy: SSL backend skip CA certificate verification

### 3.2.8 2024-04-17

- [T6168](#) (bug): add system image does not set default boot to current console type in compatibility mode
- [T6243](#) (bug): Update vyos-http-api-tools for package idna security advisory
- [T6154](#) (enhancement): Installer should ask for password twice
- [T5966](#) (default): Adjust dynamic dns configuration address subpath to be more intuitive and other op-mode adjustments
- [T5723](#) (default): mdns repeater: Always reload systemd daemon before applying changes

- [T5722](#) (bug): Failing to add route in failover if gateway not in the same interface network
- [T5612](#) (default): Miscellaneous improvements and fixes for dynamic DNS configuration
- [T5574](#) (default): Support per-service cache management for dynamic dns providers
- [T5360](#) (bug): ddclient generating abuse

### 3.2.9 2024-04-15

- [T6100](#) (bug): NAT config migration error in 1.4.0-epal if invalid address/network defined in 1.3.6 version
- [T5734](#) (bug): OpenVPN server dh-params that are not in PKI error

### 3.2.10 2024-04-14

- [T6210](#) (feature): Add container ability to configure capability sys-nice

### 3.2.11 2024-04-13

- [T6173](#) (bug): Build Causes Errors When "--version" Contains Slashes ("/")
- [T2518](#) (feature): Support NAT for ipv6(NPT)
- [T6238](#) (default): vyos-build Check pull request title requires the python script
- [T6235](#) (default): Git check PR status: conflicts and resolution

### 3.2.12 2024-04-12

- [T5872](#) (default): ipsec remote access VPN: support dhcp-interface
- [T6216](#) (bug): Upgrade error from 1.3 to 1.4 - Firewall using character '+'
- [T6214](#) (bug): Error when using some constraints
- [T6213](#) (bug): Firewall group constraints
- [T6148](#) (bug): Reset vpn ipsec command breaks tunnel and does not reset SAs that are down
- [T1487](#) (default): DNS (pdns\_recurser) stats logs not saved to disk
- [T6222](#) (bug): VRRP rfc3768-compatibility not working correctly when resulting interface name is over 15 characters
- [T6218](#) (bug): Container network interface in VRF fails to generate IPv6 link-local address
- [T5959](#) (default): Streamline dns forwarding service
- [T5846](#) (default): Refactor and simplify DUID definition in conf-mode
- [T5631](#) (feature): Ability to export the current configuration in JSON format
- [T5615](#) (default): Narrow down spurious name conflict with mdns
- [T5530](#) (default): Add LFA to IS-IS

- T5195 (default): Break up the vyos.util module
- T5124 (bug): Python3 deprecation distutils.version import LooseVersion
- T1871 (feature): add MTU option when configure limiter traffic-policy
- T874 (feature): Support for Two Factor Authentication for CLI access via Google Authenticator/OTP
- T6204 (default): Remove shebang lines from Python modules
- T6166 (bug): Tech support generation error for custom output location
- T6062 (feature): container: add support for image manipulation based on tag name
- T5877 (default): Reduce unnecessary nesting in system domain-search path and improve smoketest
- T5871 (default): ipsec remote access VPN: specify "cacerts" to disambiguate multiple remote access configurations
- T5870 (default): ipsec remote access VPN: add x509 ("pubkey") authentication
- T5772 (default): Require HTTPS API server configurations to include at least one key if key-based auth is used
- T5447 (feature): Allow static MACsec keys with peers
- T4221 (default): Add a template filter for converting scalars to single-item lists
- T3766 (feature): containers: Expanding options for networking and building containers

### 3.2.13 2024-04-11

- T4516 (feature): Rewrite system image manipulation tools in Python
- T4548 (feature): GRUB loader configuration rework
- T3774 (bug): atop logs are not limited in size
- T3574 (default): Add constraintGroup for combining validators with logical AND
- T3474 (default): Revisit storing syntax version of interface definitions in XML file
- T160 (feature): Support NAT64
- T6228 (bug): Cleanup of not existing units

### 3.2.14 2024-04-10

- T6207 (bug): image-tools: restore ability to copy config.boot.default on image install
- T5750 (bug): Upgrade from 1.3.4 to 1.4 Rolling fails QoS
- T5858 (bug): Show conntrack statistics formatting is all over the place
- T4734 (feature): Feature Request: openvpn: add OTP 2FA support

### 3.2.15 2024-04-09

- [T3409](#) (feature): Add back TCP-MSS Clamp to PMTU
- [T6121](#) (feature): Extend service config-sync for sections vpn, policy, vrf

### 3.2.16 2024-04-08

- [T6197](#) (bug): IPoE-server interface client-subnet looks broken or works with the wrong logic
- [T6196](#) (bug): Route-map and summary-only do not work in BGP aggregation at the same time
- [T6068](#) (feature): dhcp server: allow switching between load-balanced and hotspare mode

### 3.2.17 2024-04-07

- [T6205](#) (bug): ipoe: error in migration script logic while renaming mac-address to mac node
- [T6039](#) (bug): cloud-init DNS search-domain causes configuration migration/validation error
- [T5862](#) (bug): Default MTU is not acceptable in some environments
- [T6208](#) (feature): container: rename "cap-add" CLI node to "capability"
- [T6188](#) (feature): Add Firewall Rule Description to "show firewall" commands
- [T1244](#) (default): Support for StartupResync in conntrackd

### 3.2.18 2024-04-06

- [T6203](#) (enhancement): Remove obsoleted xml lib
- [T6202](#) (bug): Multi-Protocol BGP is broken by 6PE patch in upstream FRR 9.1

### 3.2.19 2024-04-05

- [T6089](#) (bug): [1.3.6->1.4.0-epa1 Migration] "ospf passive-interface default" incorrectly added
- [T2590](#) (bug): DHCPv6 not updating nameservers and search domains since replacing isc-dhcp-client with WIDE dhcp6c
- [T6199](#) (feature): spring cleaning - drop unused Python imports

### 3.2.20 2024-04-04

- T6119 (default): Use a compliant TOML parser
- T6171 (feature): dhcp server fail-over - Rename fail-over node
- T6115 (bug): Build from Git tags fail
- T5122 (feature): Move "archive-areas" to defaults.toml to support "non-free-firmware" repository
- T5121 (bug): Incorrect "architecture" config loaded
- T4951 (default): Add an op mode exception for cases when operations fail due to insufficient system resources
- T4883 (default): Add a description field for routing tables
- T4796 (bug): build-vyos-image ignores multiple options
- T4795 (feature): Cleanup custom python validators
- T4761 (default): Add a generic URL validator
- T3843 (bug): l2tp configuration not cleared after delete
- T3681 (default): The VMware Tools resume script did not run successfully in this virtual machine.
- T1991 (feature): Rework time services
- T5711 (default): Put the version data file inside the ISO image
- T5672 (default): Remove the old-style command definition importer
- T5639 (default): Group vyos-1x dependencies by their VyOS components and specify their purpose
- T5638 (default): Add support for requiring numeric values to be ranges rather than single numbers
- T5634 (default): Remove support for Blowfish and DES from OpenVPN
- T5605 (default): Do not generate keysize option in OpenVPN configs
- T5582 (default): Add a command to force NTP sync
- T5449 (default): Add options for TCP MSS probing
- T4440 (default): Add OCI compliant image labels to vyos-build and vyos containers
- T671 (enhancement): Identify and remove dead code
- T5109 (feature): Improve OCaml XML validator
- T1449 (feature): Add opportunity to include custom default configs (few) at building

### 3.2.21 2024-04-03

- T6198 (feature): configverify: add common helper for PKI certificate validation
- T6192 (feature): Multi VRF support for SSH

### 3.2.22 2024-04-02

- T6167 (bug): VNI not set on VRF after reboot
- T6151 (default): BGP VRF - Route-leaking not work when the next-hop is a recursive route.
- T6033 (bug): hsflowd fails to start when using a tunnel interface

### 3.2.23 2024-04-01

- T6195 (feature): dropbear: package upgrade 2022.83-1 -> 2022.83-1+deb12u1
- T6193 (bug): dhcp-client: invalid warning "is not a DHCP interface but uses DHCP name-server option" for VLAN interfaces
- T6178 (bug): Reverse-proxy should check that certificate exists during commit

### 3.2.24 2024-03-31

- T6186 (bug): Fix regression in 'set system image default-boot'
- T5832 (feature): Keepalived: Allow using the 'dev' statement on excluded-addresses

### 3.2.25 2024-03-28

- T6147 (bug): Conntrack not working as expected with global state-policy
- T6175 (bug): op-mode: "renew dhcp interface <name>" does not check if it's an actual DHCP interface

### 3.2.26 2024-03-26

- T6066 (bug): Setting same network in different ospf area will raise exception

### 3.2.27 2024-03-25

- T6145 (bug): Service config-sync does not rely on priorities but must

### 3.2.28 2024-03-24

- T6161 (feature): Output container images as JSON
- T6165 (bug): grub: vyos-grub-update failed to start on "slow" systems
- T6085 (bug): VTI interfaces are in UP state by default
- T6152 (bug): Kernel panic for ZimaBoard 232

### 3.2.29 2024-03-23

- T6160 (bug): isis: NameError: name 'process' is not defined
- T6131 (bug): Disabling openvpn interface(s) causes OSPF to fail to load on reboot
- T4022 (feature): Add package nat-rtsp-dkms

### 3.2.30 2024-03-22

- T6136 (bug): Configuring a dynamic address group, config script did not check whether the group was created
- T6130 (bug): [1.3.6->1.4.0-epa2 Migration] BGP "set community" missing
- T6090 (bug): [1.3.6->1.4.0-epa1 Migration] policy route fails due tcp flag case sensitivity
- T6155 (default): ixgbe: failed to initialize because an unsupported SFP+ module type was detected.
- T6125 (feature): Support 802.1ad (0x88a8) vlan filtering for bridge
- T5624 (default): Remove /etc/debian\_version from the image

### 3.2.31 2024-03-21

- T6143 (feature): Increase configuration timeout range for service config-sync

### 3.2.32 2024-03-20

- T6133 (feature): Add domain-name to commit-archive
- T6129 (feature): bgp: add route-map option "as-path exclude all"

### 3.2.33 2024-03-19

- T6127 (bug): Ability to view logs for rules with Offload not functional
- T6138 (bug): Conntrack table op-mode fails with flowtable offload entries

### 3.2.34 2024-03-15

- T6118 (feature): radvd: RFC8781: add nat64prefix support

### 3.2.35 2024-03-12

- T6020 (bug): VRRP health-check script is not applied correctly in keepalived.conf
- T5646 (bug): QoS policy limiter broken if class without match
- T2433 (feature): Improve CLI value validator performance
- T1436 (bug): Config entries with default values do not correctly show as changed

### 3.2.36 2024-03-11

- T6098 (bug): Description doesnt seem to allow for non international characters
- T6070 (bug): bnx2x NIC causes a commit error due to incorrect implementation of EEE status reading
- T2998 (bug): SNMP v3 oid "exclude" option doesn't work
- T6107 (bug): Nginx does not allow big config queries for configure endpoint API
- T6096 (bug): Config commits are not synced properly because `vyos-sync` is deleted by `vyos-router`
- T6093 (bug): Incorrect dhcp-options vendor-class-id regex
- T6083 (feature): ethtool: move string parsing to JSON parsing
- T6069 (bug): HTTP API segfault during concurrent configuration requests
- T6057 (feature): Add ability to disable syslog for conntrackd
- T5504 (feature): Keepalived VRRP ability to set more than one peer-address
- T5717 (feature): ospfv3 - add allow to set metric-type to ospf redistribution while frr docs says its possible.
- T6071 (bug): firewall: CLI description limit of 256 characters cause config upgrade issues

### 3.2.37 2024-03-08

- T6086 (bug): NAT does not work with network-groups
- T6094 (bug): Destination Nat not Making Firewall Rules
- T6061 (bug): connection-status nat destination firewall filter not working in 1.4.0-epal
- T6075 (bug): Applying firewall rules with a non-existent interface group

### 3.2.38 2024-03-07

- T6104 (bug): Regression in commit-archive for non-interactive configuration
- T6084 (bug): OpenNHRP DMVPN configuration file clean after reboot if we have any IPSec configuration
- T5348 (bug): Service config-sync can freeze the secondary router if it has commit-archive location
- T6073 (bug): Conntrack/NAT not being disabled when VRFs are defined
- T6095 (default): Tab completion for "set interfaces wireless wlan0 country-code" incorrect country "uk"

### 3.2.39 2024-03-06

- T6079 (bug): dhcp: migration fails for duplicate static-mapping

### 3.2.40 2024-03-05

- T5903 (bug): NHRP don't start on reboot from version 1.5-rolling-202401010026
- T2447 (feature): Additional Boot Argument Configuration to limit CPU C-States

### 3.2.41 2024-03-04

- T6054 (bug): load-balancing wan - doesn't configure a list of ports
- T6087 (feature): ospfv3: add support to redistribute IS-IS routes

### 3.2.42 2024-03-02

- T6081 (bug): QoS policy shaper target and interval wrong calculations

### 3.2.43 2024-02-29

- T6078 (feature): Update ethtool to 6.6
- T6077 (feature): banner: implement ASCII contest winner default logo
- T6074 (feature): container: do not allow deleting images which have a container running

### 3.2.44 2024-02-28

- T6055 (bug): PKI error: "failed to install x value" when executed the command from conf mode
- T4270 (bug): dns forwarding - When "ignore-hosts-file" is unset, local hostname of router resolves to 127.0.1.1

### 3.2.45 2024-02-27

- T6065 (bug): Duplicate lines in build-vyos-image script cause sagitta build to fail
- T5080 (bug): Conntrack enabled by default

### 3.2.46 2024-02-26

- T6064 (bug): Can not build VyOS if repository it not cloned to a branch
- T5754 (default): Update to StrongSwan 5.9.11

### 3.2.47 2024-02-25

- T6060 (feature): op-mode: container: support removing all container images at once

### 3.2.48 2024-02-24

- T5909 (bug): Container registry with authentication prevents config load (section container) after reboot

### 3.2.49 2024-02-23

- T5376 (bug): Conntrack FTP helper does not work properly
- T970 (feature): Hostname Support in NAT and Firewall Rules
- T4940 (feature): Interface debugging

### 3.2.50 2024-02-22

- T6048 (bug): Exception in event handler script
- T3902 (bug): Firewall does not load on boot, address-group not found, even though it exists

### 3.2.51 2024-02-21

- T6050 (bug): Wrong scripting commands descriptions in accel-ppp services

### 3.2.52 2024-02-19

- T5971 (default): Create the same view of ppp section for all accel-ppp services
- T6029 (default): Rewrite Accel-PPP services to an identical feature set
- T3722 (bug): op-mode IPsec show vpn ike sa always shows L-TIME 0

### 3.2.53 2024-02-18

- T6043 (bug): VxLAN and bridge error bug
- T6041 (bug): image-tools: install fails from PXE boot into live iso due to restrictive logic

### 3.2.54 2024-02-17

- T5972 (feature): login: add possibility to disable individual local user accounts

### 3.2.55 2024-02-16

- T6009 (bug): Firewall - Time not working properly when not using UTC
- T6005 (bug): Error on adding a wireguard interface to OSPFv3
- T2113 (bug): OpenVPN Options error: you cannot use --verify-x509-name with --compat-names or --no-name-remapping
- T6019 (feature): Bump nftables and libnftnl version
- T3471 (bug): DHCP hook is not able to detect all running DHCP instances
- T6015 (default): "journalctl\_charon" file does not contain data in the generated "ipsec debug-archive" file
- T6001 (default): Add option to enable resolve-via-default
- T5965 (bug): WWAN modems using raw-ip do not work with dhclient/dhcp6c
- T5418 (bug): PPPoE-Server Client IP pool Subnet
- T5245 (bug): Wireless interfaces do not get IPv6 link-local address assigned

### 3.2.56 2024-02-15

- T5977 (bug): nftables: Operation not supported when using match-ipsec in outbound firewall
- T2612 (bug): HTTPS API, changing API key fails but goes through
- T5989 (bug): IP subnets not usable in UPnP ACLs
- T5890 (default): OTP key generation is broken
- T5719 (default): mdns repeater: Add op-mode commands
- T4839 (feature): Dynamic Firewall groups
- T4801 (feature): Support for building AWS-ready ISO
- T3993 (enhancement): Extend HTTP API GraphQL support
- T3991 (bug): PKI operational command return traceback
- T3780 (bug): VTI not being brought down when tunnel is down
- T3001 (feature): Disable spectre mitigation patches from CLI
- T562 (feature): PDNS: Add support for authoritative dns server
- T71 (feature): Add virtual IP and route installation policy options for IPsec
- T5496 (default): `show firewall` error
- T4038 (default): Rewrite `vyatta-image-tools.pl` in Python
- T4997 (default): Add DHCP client user hooks dir
- T775 (feature): Config Sync between two VyOS routers
- T381 (feature): config nodes for EasyRSA CAs
- T118 (feature): Native Zabbix Support

### 3.2.57 2024-02-14

- T6034 (feature): rpki: move file based SSH keys for authentication to PKI subsystem
- T5981 (bug): IPsec site-to-site migrated PKI ca certificates are created with an '@'
- T5930 (bug): vrf - route-leak not work using route-target both command.
- T5709 (bug): IPoE-server fails if next pool mentioned but not defined
- T4119 (bug): Issue with l2tp remote-access ipv6 configuration
- T2044 (bug): RPKI doesn't boot properly
- T6032 (feature): bgp: add EVPN MAC-VRF Site-of-Origin support
- T5960 (default): Rewriting authentication section in accel-ppp services

### 3.2.58 2024-02-13

- T5928 (bug): Configuration fails to load on boot if offloading has VLAN interfaces defined
- T5482 (bug): Chrony NTP Server Fails To Sync Time
- T5064 (bug): Value validation for domain-groups seems to be broken

### 3.2.59 2024-02-12

- T6010 (bug): Support setting multiple values in BGP path-attribute
- T6004 (bug): RPKI is not configured
- T5952 (default): DHCP allow same MAC Address on same subnet
- T5849 (feature): Add SRv6 route commands

### 3.2.60 2024-02-10

- T6023 (bug): rpki: add support for CLI knobs expire-interval and retry-interval
- T1090 (default): Webproxy overhaul

### 3.2.61 2024-02-09

- T6028 (bug): QoS policy shaper wrong class\_id\_max and default\_minor\_id
- T6026 (bug): QoS hide attempts to delete qdisc from devices
- T5788 (feature): frr: update to 9.1 release
- T5703 (bug): QoS config on pppoe interface resets back to fq\_codel after tunnel reboots
- T5685 (feature): Keepalived VRRP prefix is not necessary for the virtual address

### 3.2.62 2024-02-08

- T6014 (feature): Bump keepalived version
- T5910 (bug): Grub problem(?) Serial Console no longer working
- T6021 (bug): QoS r2q wrong calculation

### 3.2.63 2024-02-07

- T6017 (bug): Update vyos-http-api-tools for security advisory
- T6016 (bug): Resolve intermittent failures in cleanup function after failed image install
- T6024 (feature): bgp: add additional missing FRR features
- T6011 (feature): rpki: known-hosts-file is no longer supported by FRR CLI - remove VyOS CLI node

- T5998 (feature): replay\_window setting under vpn in config

### 3.2.64 2024-02-06

- T6018 (default): smoketest: updating http-api framework requires a pause before test
- T5921 (bug): Trying to commit an OpenConnect configuration without any local users results in an exception
- T5687 (feature): Implement ECS settings for PowerDNS recursor

### 3.2.65 2024-02-05

- T5974 (bug): QoS policy shaper is currently miscalculating bandwidth and ceil values for the default class
- T5865 (feature): Rewrite ipv6 pool section to ipv6 named pools in Accel-ppp services

### 3.2.66 2024-02-02

- T5739 (bug): Password recovery does not work if public keys are configured
- T5955 (feature): Rootless containers/set uid/gid for container
- T5941 (bug): [1.3.5 -> 1.4.0-RC1 Migration] Orphaned Configuration Nodes Cause Issues
- T6003 (feature): Add 'show rpki as-number' and 'show rpki prefix'
- T5848 (feature): Add triple-isolate flow isolation option to CAKE QoS policy

### 3.2.67 2024-02-01

- T5995 (bug): Kernel NIC-drivers for Huawei NICs are not properly enabled
- T5978 (bug): ethernet: hw-tc-offload does not actually get enabled on the NIC
- T5979 (enhancement): Add configurable kernel boot parameters
- T5973 (bug): vrf: RTNETLINK answers: File exists
- T5967 (bug): Multi-hop BFD connections can't be established; please add minimum-ttl option.
- T5619 (default): Update the Intel ixgbe driver due to issues with Intel X533

### 3.2.68 2024-01-31

- T6000 (bug): [1.3.x -> 1.5.x] migrating threw exception in /opt/vyatta/etc/config-migrate/migrate/https/5-to-6, performed workaround
- T5999 (bug): load-balancing reverse-proxy can't configure root as a redirect

### 3.2.69 2024-01-30

- T5980 (feature): Add image-tools support for configurable kernel boot options

### 3.2.70 2024-01-29

- T5988 (bug): image-tools: a check of valid image name is missing from 'add image'
- T5994 (bug): Fix typo in 'remote' module preventing 'add system image' via ftp

### 3.2.71 2024-01-26

- T5957 (bug): Firewall fails to delete inbound-interface name
- T5779 (bug): custom conntrack timeout rule not applicable
- T5984 (feature): Add user util numactl

### 3.2.72 2024-01-25

- T5983 (bug): image-tools: minor regression in pruning version files in compatibility mode
- T5927 (bug): QoS policy shaper-hfsc class does not have a `bandwidth` node but requires one in the check
- T5834 (bug): Rename 'enable-default-log' to 'default-log'

### 3.2.73 2024-01-22

- T5968 (feature): hsflowd: add VRF support
- T5975 (bug): GraphQL expects script otp.py that does not exists in 1.4
- T5961 (bug): QoS policy shaper vif with ceiling fails on commit
- T5958 (bug): QoS policy shaper-hfsc is not implemented
- T5160 (feature): Firewall refactor
- T5969 (feature): op-mode: list multicast group membership

### 3.2.74 2024-01-21

- T5799 (bug): vyos unbootable after 1.4-rolling-202308240020 to 1.5-rolling-202312010026 upgrade
- T5787 (bug): dhcp-server allows duplicate static-mapping for the same IP address
- T5692 (enhancement): NTP leap smear
- T5954 (feature): Enable nvme\_hwmon and drivetemp in KERNEL

### 3.2.75 2024-01-20

- T5915 (bug): Firewall zone - Re add op-mode commands
- T5805 (bug): Missed per-interface statistic in telegraf
- T5724 (feature): About dhcp client hooks
- T5577 (bug): Optimize PAM configs for RADIUS/TACACS+
- T5550 (bug): Source validation on interface does not work properly
- T5267 (bug): Another corruption on upgrade
- T5239 (bug): frr 'hostname' missing or incorrect, and domain-name missing totally
- T5219 (bug): ddclient: Cloudflare doesn't require login
- T5217 (feature): Add firewall SYNPROXY
- T5203 (feature): load-balancing wan add systemd unit instead of old vyatta-wanloadbalance.init
- T5199 (bug): Salt-minion cannot connect to server in python 3.10 and up
- T5138 (feature): Add patch to accel-ppp build L2TP LNS use Calling-Number as RADIUS Calling-Station-ID
- T5054 (bug): ipsec: "show vpn ipsec remote-access" does not list active connections
- T5053 (bug): Vyatta-cfg Post-Removal Hook Tries to Disable Deleted Service
- T5035 (feature): Add more actions to policy route rule
- T4990 (bug): Commit results may not be properly saved if power is cut immediately after a successful commit
- T4988 (default): Expose time and size conversion functions as Jinja2 filters
- T4986 (feature): Ability to filter traffic originating from the router itself via firewall
- T4963 (default): vyos.ethtool: improve/fix driver name detection
- T4935 (bug): ospfv3: "not-advertise" and "advertise" conflict
- T4897 (bug): Setting 'source-address' or `source-interface` on existing vxlan interface doesn't work
- T4888 (default): Rewrite the conntrack sync script using vyos.opmode
- T4863 (feature): need an option for route policy to apply to dynamic interfaces l2tp\*/ipoe\*/pppoe\* (for TCP MSS setting)
- T4817 (feature): Please add support for RFC 9234
- T4765 (default): Normalize field names in op mode JSON outputs
- T4751 (enhancement): Feature Request: system login: 2FA OTP key generator in VyOS CLI
- T4726 (default): Add completion and validation for the accel-ppp RADIUS vendor option
- T4722 (default): Improve abbreviation/acronym consistency
- T4172 (feature): Patch ndppd to not read route table if there are no auto prefixes
- T4085 (feature): Rewrite L2TP/PPTP/SSTP/PPPoE services to get\_config\_dict
- T4031 (feature): Ability to configure DMVPN in vrf

- T4030 (bug): SR-IOV and interface renaming bug
- T4014 (feature): Add “command” and “arg” configuration options for containers
- T3965 (default): arm: Extend configure scripts to allow for arm builds
- T3813 (bug): Some custom sysctl parameters can't be applied bug
- T3778 (bug): Abnormal network communication and settings
- T3591 (bug): OpenVPN with/without VRF not working (NordVPN)
- T3372 (feature): Support public HTTPS repos in live-build
- T5963 (bug): QoS policy shaper rate calculations could be wrong for some ethernet devices
- T5962 (feature): QoS policy set default speed to 100mbit or 1gbit instead of 10mbit
- T5697 (bug): event-handler keep failing
- T4779 (default): Make raw op mode command outputs use bytes for data amount values

### 3.2.76 2024-01-19

- T5897 (bug): VyOS with Cloud-init and VRF stuck at reboot/shutdown process
- T5554 (bug): Disable sudo for PAM RADIUS
- T4754 (default): Improvement: system login: show configured 2FA OTP key
- T5857 (bug): show interfaces wireless info
- T5841 (default): Remove old ssh-session-cleanup.service
- T5543 (bug): Fix source address handling in static joins
- T5884 (default): Minor description fix (op-mode: generate wireguard)
- T5781 (default): Add ability to add additional minisign keys

### 3.2.77 2024-01-18

- T5863 (bug): Failure to Load Config on Recent 1.5 Versions
- T4638 (bug): Deleting a parent interface does not delete its underlying VLAN interfaces
- T5953 (default): Rename 'close\_action' value from `hold` to `trap` in IPSEC IKE
- T905 (bug): The command show remote-config does not work for remote-platform openvpn

### 3.2.78 2024-01-17

- T5923 (bug): Config mode system\_console.py is not aware of revised GRUB file structure
- T4658 (feature): Rename DPD action `hold` to `trap`
- T5932 (bug): 1.4-rolling-202304120317 to 1.4.0-rc1: dynamic dns migration fail

### 3.2.79 2024-01-16

- T5951 (bug): [1.4.0-RC2] show hardware dmi Operational Mode Command Broken
- T5937 (bug): [1.3.5 -> 1.4.0-RC1 Migration] IPv6 BGP Neighbor Peer Groups Missing / Not Migrated
- T5889 (bug): Migration NAT 5-to-6 bug
- T5859 (bug): Invalid format of pool range in accel-ppp services
- T5842 (feature): Rewrite PPTP service to get\_config\_dict
- T5801 (feature): Rewrite L2TP service to get\_config\_dict
- T5688 (default): Create the same view of pool configuration for all accel-ppp services

### 3.2.80 2024-01-15

- T5944 (bug): "reboot in 1" not working
- T5936 (bug): [1.3.5 -> 1.4.0-RC1 Migration] OSPF Passive Interface Configuration Not Working Correctly
- T5247 (bug): the bug of the command "show interfaces system"
- T5901 (bug): Cloud-init and DHCP exit hook errors
- T4856 (bug): DHCP-client exit hook for IPsec is incorrect
- T2556 (bug): "show interfaces vrrp" does not return any interface

### 3.2.81 2024-01-14

- T4428 (feature): Update ddclient to newer version

### 3.2.82 2024-01-12

- T5925 (feature): Containers change systemd KillMode
- T5920 (bug): Quick Start documentation contains error
- T5919 (bug): Firewall - opmode for ipv6
- T5306 (default): bgp config migration failed with v6only option configured with peer-group
- T3429 (bug): Hyper-V integration services not working on VyOS 1.4 (sagitta/current)

### 3.2.83 2024-01-11

- T5896 (bug): Config Error on Boot with Podman and Firewall
- T5532 (bug): After add system image the boot stuck and works again after the second reboot
- T5512 (bug): build linux-firmware script cannot expand asterisks if firmware name is a glob string
- T5379 (bug): show system updates doesnt seem to be working
- T5275 (default): Add op mode commands for exporting certificates to PEM files with correct headers
- T5274 (default): Add a deprecation warning for OpenVPN site-to-site with pre-shared secret
- T5262 (default): Warn the user about unsaved config on reboot/shutdown attempts
- T5257 (feature): Cannont assign netflow source ip to ip in non default VRF
- T5026 (feature): Python3 modules crypt and spwd are deprecated
- T5814 (bug): VyOS 1.3 to 1.4 LTS Firewall ruleset migration script breaks configuration
- T4610 (bug): Firewall with 20K entries cannot load after reboot
- T3191 (bug): PAM RADIUS freezing when accounting does not configured on RADIUS server
- T5917 (feature): Restore annotations of (running)/(default boot) in select image list
- T5916 (default): Added segment routing check for index size and SRGB size
- T5913 (feature): Allow for Peer-Groups in ipv4-labeled-unicast SAFI

### 3.2.84 2024-01-10

- T5918 (bug): Verification problem for `set vpn ipsec interface`
- T5911 (bug): pki: service update ignored if certificate name contains a hyphen (-)
- T5886 (feature): Add support for ACME protocol (LetsEncrypt)
- T5766 (bug): http: rewrite conf-mode script to get\_config\_dict()
- T5144 (default): Modernize dynamic dns operation
- T4689 (feature): Support RFS(Receive Flow Steering)
- T4659 (feature): Use vtysh to display bridge and some interface parameter information
- T4646 (bug): USB serial output console does not work
- T4577 (bug): WWAN commit failed which simple config
- T4502 (feature): Consider implementing (NAT/other) flow table offload
- T4446 (default): Unified CLI for displaying neighbors (ARP, IP, and NDP)
- T4427 (default): Remove the vyos-utils package list from vyos-build
- T4300 (feature): Extend list of supported interfaces for Cloud-init Network Configuration

- T4250 (bug): Organize logrotate settings to avoid duplicates
- T4236 (feature): Generate ovpn openvpn client configuration files
- T4222 (feature): Support for TWAMP as round-trip metric
- T3833 (bug): Cloud-init not finding data source in OpenStack
- T5902 (bug): http: remove virtual-host configuration in webserver
- T3499 (bug): Podman is not compatible with nat rules
- T3430 (bug): Cloud-init failing with “Unable to render networking” on VyOS 1.3
- T3011 (bug): router becomes unreachable for few minutes when vti interfaces goes down
- T5791 (default): Update dynamic dns configuration path to be consistent with other areas of VyOS
- T5708 (default): Additional dynamic dns improvements to align with ddclient 3.11.1 release
- T5573 (bug): Fix ddclient cache entries
- T5012 (feature): Control network configuration from Cloud-Init config
- T3116 (feature): Support back-end L4 level load balancing
- T5614 (default): Add conntrack helper matching on firewall
- T4782 (enhancement): Allow multiple CA certificates (on e.g. EAPoL)
- T2199 (default): Rewrite firewall in new XML/Python style

### 3.2.85 2024-01-09

- T5898 (bug): Replace partprobe with partx due to unable to install VyOS
- T5838 (feature): Add Infiniband kernel modules
- T5785 (bug): API output of show container image broken
- T5410 (feature): Improve `utils.convert.convert\_data()` to process all stdtypes
- T5269 (default): OpenVPN non-TLS site-to-site mode deprecation
- T5249 (feature): Add rollback-soft feature to rollback without a reboot
- T4944 (default): Prevent op mode functions from returning bare literals in raw output
- T4910 (default): Rewrite the remote access VPN op mode in the new style
- T4470 (feature): Rewrite load-balancing wan to XML/Python
- T3763 (bug): wireguard checks if port already binding
- T3489 (bug): NUMA has been disabled for the past few years and no-one has noticed
- T3476 (feature): Update availability check
- T2845 (bug): BGP conf\_mode unable to delete configuration with peer-group
- T2844 (bug): BGP conf\_mode errors disable-send-community
- T2755 (default): Requirements for partial interface setup
- T2721 (enhancement): Set FQ-CoDel as the default queueing mechanism for every class in Shaper

- [T2511](#) (feature): Migrate vyatta-op-quagga to new XML format
- [T2302](#) (default): Convert configuration scripts from executables to modules and use a script runner
- [T2281](#) (feature): DHCP and Static IPs on Same Interface
- [T2216](#) (default): Containerized third-party applications for VyOS
- [T2171](#) (feature): Unify creation and manipulation of interfaces
- [T1759](#) (feature): Replacing Vyatta::Interface perl
- [T2408](#) (enhancement): DHCP Relay upstream and downstream interfaces
- [T1297](#) (feature): Add GARP settings to VRRP/keepalived

### 3.2.86 2024-01-08

- [T5888](#) (bug): Firewall upgrade fails because of icmpv6
- [T5844](#) (bug): HTTPS API doesn't start without configured keys even when GraphQL authentication type is set to token
- [T5664](#) (bug): 1.4 user has no permissions?
- [T5215](#) (default): Add a built-in ICMP health check for VRRP groups
- [T5045](#) (bug): BFD is not starting after upgrade to 1.4-rolling-202302150317
- [T4193](#) (default): Add support for transparent firewall
- [T3754](#) (default): Make config scripts more testable
- [T3663](#) (default): Use inotify file watching where applicable
- [T3480](#) (bug): Does not possible to change console baud-rate
- [T2897](#) (default): Remove cluster command
- [T5904](#) (feature): op-mode: add "show ipv6 route vrf <name> <prefix>" command

### 3.2.87 2024-01-07

- [T5891](#) (bug): OpenVPN IPv6 config issue with 1.4-rc1
- [T5887](#) (feature): Upgrade Linux Kernel to 6.6.y (2023 LTS edition)

### 3.2.88 2024-01-06

- [T3670](#) (feature): Option to disable HTTP port 80 redirect

### 3.2.89 2024-01-05

- T3642 (feature): PKI configuration
- T5894 (feature): Extend `get_config_dict()` with additional parameter `with_pki` that defaults to `False`

### 3.2.90 2024-01-04

- T4072 (feature): Feature Request: Firewall on bridge interfaces
- T3459 (default): Inform the user when unable to install outdated image

### 3.2.91 2024-01-03

- T5880 (bug): `verify_source_interface` should not allow dynamic interfaces like `ppp`, `l2tp`, `ipoe` or `sstp` client interfaces
- T5879 (bug): tunnel: sourcing from dynamic `pppoe0` interface will fail on reboots
- T4500 (bug): Missing firewall logs

### 3.2.92 2024-01-02

- T5885 (default): `image-tools`: relax restriction on image-name length from 32 to 64

### 3.2.93 2024-01-01

- T5883 (bug): Preserve file ownership in `/config` subdirs on add system image
- T5474 (feature): Establish common file name pattern for XML conf mode commands

### 3.2.94 2023-12-30

- T5875 (bug): login: removing and re-adding a user keeps the home directory but UID will change, thus SSH keys no longer work
- T5653 (feature): Command to display fingerprint

### 3.2.95 2023-12-29

- T5829 (bug): Can't Add IPv6 Address to Containers
- T5852 (bug): Reboots fail with `eapol` WAN interface
- T5869 (bug): `vyos.template.first_host_address()` does not honor RFC4291 section 2.6.1

### 3.2.96 2023-12-28

- T4163 (feature): [BMP-BGP] Routing monitoring feature
- T5867 (feature): Upgrade podman to Debian Trixie version 4.7.x
- T5866 (feature): Add op-mode command to restart IPv6 RA daemon
- T5861 (bug): Flavor build system fails with third-party packages
- T5854 (feature): Extend override-default script to allow embedded default value settings
- T5792 (default): Upgrade ddclient 3.11.2 release

### 3.2.97 2023-12-25

- T5855 (feature): Migrate "set service lldp snmp enable" -> "set service lldp snmp"
- T5837 (bug): vyos.configdict.node\_changed does not return keys per adding
- T5856 (bug): SNMP service removal fails

### 3.2.98 2023-12-24

- T5853 (default): Typo interfaces-virtual-ethernet.xml.in

### 3.2.99 2023-12-22

- T5804 (bug): SNAT "any" interface error
- T4760 (bug): VyOS does not support running multiple instances of DHCPv6 clients

### 3.2.100 2023-12-21

- T5778 (bug): The show dhcp server leases operation mode command does not work as expected
- T5775 (default): Migrated Firewall Global State Policy ineffective on latest firewall zone config
- T5637 (bug): Firewall default-action log
- T5796 (bug): Openconnect - HTTPS security headers are missing
- T3580 (feature): Refactoring firewall ipv6 rule icmpv6
- T2898 (feature): Support NDP proxy
- T2229 (feature): PPPoE Default Queue type selection

### 3.2.101 2023-12-20

- T5823 (feature): Protocol BGP add default values for config dictionary
- T5798 (enhancement): reverse-proxy load-balancing service should support multiple certificates for frontend

### 3.2.102 2023-12-19

- T5828 (default): Fix GRUB installation on arm64

### 3.2.103 2023-12-18

- T5751 (feature): Adjust new image tools for non-interactive use
- T5831 (feature): show system image should reverse order by addition date
- T5825 (bug): image-tools: restore authentication on 'add system image'
- T5821 (bug): image-tools: restore vrf-aware 'add system image'
- T5819 (bug): Don't echo password on install image
- T5806 (bug): Clear old raid data on new install image
- T5789 (bug): image-tools should copy ssh host keys on image update
- T5758 (default): Restore scanning configs when live installing

### 3.2.104 2023-12-15

- T5824 (bug): busybox cannot connect some websites from initramfs
- T5803 (default): git/github: Adjust configuration for safe and baseline defaults

### 3.2.105 2023-12-14

- T5773 (bug): Unable to load config via HTTP
- T5816 (bug): BGP Large Community List Validation Broken
- T5812 (bug): rollback check max revision number does not work
- T5749 (feature): Show MAC address VRF and MTU by default for "show interfaces"
- T5774 (bug): commit-archive to FTP server broken after update (VyOS 1.5-rolling)
- T5826 (default): Add dmicode as an explicit dependency
- T5793 (default): mdns-repeater: Cleanup avahi-daemon configuration in /etc

### 3.2.106 2023-12-13

- T591 (feature): Support SRv6

### 3.2.107 2023-12-12

- T4704 (feature): Allow to set metric (MED) to rtt with rtt,+rtt or -rtt
- T5815 (enhancement): Add load\_config module
- T5413 (default): Deny the opportunity to use one public/private key pair on both wireguard peers.

### 3.2.108 2023-12-11

- T5741 (bug): WAN Load Balancing failover route tables aren't created

### 3.2.109 2023-12-10

- T5658 (default): Add VRF support for mtr

### 3.2.110 2023-12-09

- T5808 (bug): op-mode: ipv6 ospfv3 graceful-restart description contains incorrect info
- T5802 (bug): ping (ip or hostname) interface <tab> produces error
- T5747 (feature): op-mode add MAC VRF and MTU for show interfaces summary
- T3983 (bug): show pki certificate Doesn't show x509 certificates

### 3.2.111 2023-12-08

- T5782 (enhancement): Use a single config mode script for https and http-api
- T5768 (enhancement): Remove auxiliary http-api.conf for simplification of http-api config mode script
- T5809 (default): Enable GRUB support for gzip compressed kernels

### 3.2.112 2023-12-04

- T5769 (bug): VTI tunnels lose their v6 Link Local addresses when set down/up

### 3.2.113 2023-12-03

- T5753 (feature): Add VXLAN vnifilter support
- T5759 (feature): Change VXLAN default MTU to 1500 bytes

### 3.2.114 2023-11-30

- T4601 (bug): dhcp : relay agent IP address issue.

### 3.2.115 2023-11-28

- T4276 (bug): IPsec peers dh-group negotiation issue with pfs enabled and multiple proposals configured with IKEv1

### 3.2.116 2023-11-27

- T5763 (bug): Fix imprecise check for remote file name in vyos-load-config.py
- T5783 (feature): frr: smoketests must notice any daemon crash

### 3.2.117 2023-11-26

- T5760 (feature): DHCP client custom dhcp-options
- T2405 (feature): archive to GIT or other platform

### 3.2.118 2023-11-25

- T5655 (bug): commit-archive: Ctrl+C should not error out with stack trace, signal should be caught
- T4946 (default): Rewrite "add system image" in the new op-mode
- T4454 (default): `install-image` should check free storage

### 3.2.119 2023-11-24

- T5776 (feature): Enable VFIO support
- T5402 (bug): VRRP router with rfc3768-compatibility sends multiple ARP replies
- T3895 (default): VYOS firewall rules do not adhere to time schedule unless placed in UTC mode.

### 3.2.120 2023-11-23

- T4891 (bug): BFD flapping loop
- T4867 (bug): "show bgp neighbors ... advertised-routes" and some other commands fail for IPv4 neighbors

### 3.2.121 2023-11-22

- T5767 (feature): Add reboot and poweroff the system via API
- T5729 (bug): Firewall, nat and policy route - Switch to valueless
- T5681 (feature): Interface match - Simplified and unified cli
- T4877 (bug): Need verification in using import vrf and import vpn, export vpn commands
- T4021 (bug): Long commit time on bridge interface with 1-4094 allowed VLAN tags
- T5338 (feature): Add 'mpls bgp forwarding' feature
- T3818 (bug): BGP export route-map only works after bgpd restart
- T5590 (default): Firewall "log enable" logs every packet
- T5426 (default): Add exceptions in vici functions calls

### 3.2.122 2023-11-21

- T5762 (bug): http: api: smoketests fail as they can not establish IPv6 connection to uvicorn backend server

### 3.2.123 2023-11-20

- T2816 (default): Rewrite IPsec scripts with the new XML/Python approach

### 3.2.124 2023-11-18

- T1354 (feature): Add support for VLAN-Aware bridges

### 3.2.125 2023-11-16

- T5726 (bug): HTTPS API image cannot be updated
- T5738 (feature): Extend XML building blocks
- T5736 (feature): igmp: migrate "protocols igmp" to "protocols pim"
- T5733 (feature): pim(6): rewrite FRR PIM daemon configuration to get\_config\_dict() and add missing IGMP features
- T5689 (default): FRR 9.0.1 in VyOS current segfaults on show rpki prefix \$prefix
- T5595 (feature): Multicast - PIM bfd feature enable
- T3638 (bug): Passwords With Dollar Sign Set Incorrectly

### 3.2.126 2023-11-15

- T5695 (feature): Build FRR with LUA scripts `--enable-scripting` option
- T5665 (bug): radius user not working
- T5728 (bug): Improve compatibility between OpenVPN on VyOS 1.5 and OpenVPN Connect Client
- T5732 (bug): generate firewall rule-resequence drops geoip country-code from output
- T5661 (enhancement): Add `show show ssh dynamic-protection attacker` and `show log ssh dynamic-protection`
- T1276 (bug): dhcp relay + VLAN fails

### 3.2.127 2023-11-13

- T5698 (feature): EVPN ESI Multihoming
- T5563 (bug): container: Container environment variable cannot be set
- T5706 (bug): Systemd-udevd high CPU utilization for multiple dynamic ppp/l2tp/ipoe interfaces

### 3.2.128 2023-11-10

- T5727 (bug): validator: Use native URL validator instead of regex-based validator

### 3.2.129 2023-11-08

- T5720 (bug): PPPoE-server adding new interface does not work
- T5716 (bug): PPPoE-server shaper template bug down-limiter option does not rely on fwmark
- T5702 (feature): Add ability to set `include_ifmib_iface_prefix` and `ifmib_max_num_ifaces` for SNMP
- T5648 (bug): ldpd neighbour template errors
- T5564 (bug): Both `show firewall group` and `show firewall summary` fails
- T5559 (feature): Selective proxy-arp/proxy-ndp when doing SNAT/DNAT
- T5541 (bug): Zone-Based Firewalling in VyOS Sagitta 1.4
- T5513 (bug): Anomalies in `show firewall` command after refactoring
- T4864 (bug): ``show firewall`` command errors

### 3.2.130 2023-11-07

- [T5586](#) (feature): Disable by default SNMP for Keepalived VRRP

### 3.2.131 2023-11-06

- [T5705](#) (bug): rsyslog - Not working when using facility=all
- [T5704](#) (feature): PPPoE-server add max-starting option
- [T5707](#) (bug): Wireguard peer public key update leaves redundant peers and breaks connectivity
- [T4269](#) (feature): node.def generator should automatically add default values

### 3.2.132 2023-11-05

- [T4020](#) (feature): Add ability to control FRR daemons options

### 3.2.133 2023-11-03

- [T5700](#) (bug): Monitoring telegraf deprecated plugins inputs outputs
- [T5018](#) (bug): Redirect to IFB removed after change in qos policy

### 3.2.134 2023-11-02

- [T5701](#) (feature): Update telegraf package

### 3.2.135 2023-11-01

- [T5690](#) (bug): Change to definition of environment variable 'vyos\_rootfs\_dir' is incorrect

### 3.2.136 2023-10-31

- [T5699](#) (feature): vxlan: migrate "external" CLI know to "parameters external"
- [T5668](#) (feature): Disable VXLAN bridge learning and enable neigh\_suppress when using EVPN

### 3.2.137 2023-10-27

- [T5652](#) (bug): Config migrate to image upgrade does not properly generate home directory
- [T4057](#) (bug): Commit time for deleting sflow configuration ~1.5 min

### 3.2.138 2023-10-26

- T5683 (bug): reverse-proxy pki filenames mismatch
- T4903 (bug): conntrack ignore does not support IPv6 addresses
- T4309 (feature): Support network/address-groups and ipv6-network/ipv6-address-groups in conntrack ignore
- T5606 (feature): IPsec VPN: Allow multiple CAs certificates
- T5650 (default): Progressbars suffer from staircasing effect
- T5568 (default): Install image from live ISO always defaults boot to KVM entry
- T3509 (default): No BCP38 for IPv6 on VyOS

### 3.2.139 2023-10-23

- T5299 (bug): QoS shaper ceiling does not work
- T5667 (feature): BGP label-unicast - enable ecmp
- T5337 (bug): MPLS/BGP: Route leak does not happen from the VPNv4 table to specific vrf

### 3.2.140 2023-10-22

- T5254 (bug): Modification of any interface setting sets MTU back to default when MTU has been inherited from a bond
- T5671 (feature): vxlan: change port to IANA assigned default port

### 3.2.141 2023-10-21

- T5670 (bug): bridge: missing member interface validator
- T5617 (feature): Add an option to exclude single values to the numeric validator
- T5414 (bug): dhcp-server does not allow valid bootfile-names
- T5261 (feature): Add AWS gateway load-balanceing tunnel handler (gwlbun)
- T5260 (bug): Python3 module crypt is deprecated
- T5191 (default): Replace underscores with hyphens in command-line options generated by vyos.opmode
- T5172 (default): Set Python3 version dependency for vyos-1x to 3.10
- T4956 (default): 'show hardware cpu' issue on arm64
- T4837 (default): Expose "show ip route summary" in the op mode API
- T4770 (feature): Rewrite OpenVPN op-mode to vyos.opmode format
- T4657 (bug): op-mode scripts with type hints in `return` do not work
- T4604 (bug): bgpd eats huge amount of memory (about 500Megs a day)
- T4432 (default): Display load average normalized according to the number of CPU cores

- [T4416](#) (default): Convert 'traceroute' operation to the new syntax and expand available options using python
- [T4402](#) (bug): OpenVPN client-ip-pool option is broken
- [T3433](#) (default): A review of the use of racist language in VyOS
- [T2719](#) (feature): Standardized op mode script structure

### 3.2.142 2023-10-20

- [T5233](#) (bug): Op-mode flow-accounting netflow with disable-imt errors
- [T5232](#) (bug): Flow-accounting uacstd.service cannot restart correctly

### 3.2.143 2023-10-19

- [T4913](#) (default): Rewrite the wireless op mode in the new style

### 3.2.144 2023-10-18

- [T5642](#) (bug): op cmd: generate tech-support archive: does not work
- [T5521](#) (bug): Home owner directory changed to vyos for the user after reboot

### 3.2.145 2023-10-17

- [T5662](#) (bug): Fix indexing error in configdep script organization
- [T5235](#) (bug): SSH keys with special characters cannot be applied via Cloud-init

### 3.2.146 2023-10-16

- [T5165](#) (feature): Policy local-route ability set protocol and port

### 3.2.147 2023-10-14

- [T5629](#) (bug): Policy local-route bug after migration to destination node address

### 3.2.148 2023-10-13

- [T5227](#) (feature): mDNS reflector should allow additional domains to browse and allow filtering services
- [T5166](#) (feature): Remove local minisign package from build repo for 1.4
- [T5118](#) (bug): Cleanup vestigial ntp completion script
- [T5115](#) (default): Support custom port for name servers for forwarding zones
- [T5113](#) (default): PDNS: Support custom port for DNS forwarders
- [T5112](#) (feature): Enable support for Network Time Security (NTS) for chrony

- T5143 (enhancement): Apply constraint on powerdns forward-zones configuration

### 3.2.149 2023-10-12

- T5649 (bug): vyos-1x should generate XML cache after building command templates for less cryptic error on typo

### 3.2.150 2023-10-10

- T5489 (feature): Change to BBR as TCP congestion control, or at least make it an config option
- T5479 (bug): Helper leftovers found in nftables (firewall) even with all helpers disabled
- T5436 (bug): vyos-preconfig-bootup.script is missing
- T5014 (feature): Destination NAT - Add Load Balancing capabilities

### 3.2.151 2023-10-08

- T5630 (feature): pppoe: allow to specify MRU in addition to already configurable MTU

### 3.2.152 2023-10-06

- T5096 (feature): Change 'accept' firewall rule action from 'return' to 'accept'
- T5576 (feature): Add bgp remove-private-as all option
- T3506 (default): Migrate loadkey command to op-mode

### 3.2.153 2023-10-05

- T4320 (default): Remove legacy version files in vyatta-cfg-system/cfg-version

### 3.2.154 2023-10-04

- T5632 (feature): Add jq package to parse JSON files
- T3655 (bug): NAT Problem with VRF
- T5585 (bug): Fix file access mode for dynamic dns configuration

### 3.2.155 2023-10-03

- T5618 (bug): Flow-accounting crushes when IMT is enabled
- T5561 (feature): NAT - Inbound or outbound interface should not be mandatory
- T5553 (feature): Firewall - Add action continue
- T5250 (bug): Firewall - show firewall group
- T4383 (bug): Flow Accounting returns permission error and fails to start
- T5626 (feature): Only select required Kernel CGROUP controllers
- T5628 (feature): op-mode: login: DeprecationWarning: 'spwd'

### 3.2.156 2023-10-01

- T936 (feature): Reimplementation of tech-support diagnostic file generation

### 3.2.157 2023-09-30

- T5048 (bug): QoS doesn't work correctly root task
- T4989 (bug): QoS Policy Limiter - classes for marked traffic do not work

### 3.2.158 2023-09-28

- T5596 (feature): bgp: add new features from FRR 9
- T5412 (feature): Add support for extending config-mode dependencies in supplemental package

### 3.2.159 2023-09-26

- T5480 (bug): Ability to disable SNMP for VRRP keepalived service

### 3.2.160 2023-09-25

- T5533 (bug): Keepalived VRRP IPv6 group enters in FAULT state

### 3.2.161 2023-09-24

- T5511 (feature): Cleanup of unused directories (and files) in order to shrink image-size

### 3.2.162 2023-09-23

- T5518 (default): Add MLD protocol support

### 3.2.163 2023-09-22

- T5602 (feature): For reverse-proxy type of load-balancing feature, support "backup" option in backends configuration
- T5609 (enhancement): Add util to get drive device name from id
- T5608 (enhancement): Rewrite add/delete raid member to Python and remove from vyatta-op
- T5607 (bug): Adjust RAID smoketest for non-deterministic SCSI device probing

### 3.2.164 2023-09-20

- T5588 (bug): Add kernel conntrack\_bridge module
- T5271 (default): Add support for peer-fingerprint to OpenVPN
- T5241 (feature): Support veth interfaces to working with netns
- T5238 (default): interface virtual-etherne - error when it doesn't use a peer
- T5592 (feature): salt: upgrade minion to 3005.2

### 3.2.165 2023-09-19

- T5597 (feature): isis: add new features from FRR 9.
- T4284 (feature): QoS: rewrite to XML and Python

### 3.2.166 2023-09-18

- T5419 (feature): Software/Hardware fastpath with nftables flowtable

### 3.2.167 2023-09-15

- T5581 (feature): Add "show ip nht" op-mode command (IPv4 nexthop tracking table)

### 3.2.168 2023-09-11

- T5567 (bug): vyos-1x: webproxy: maximum-object-size allowed ranges not in sync with Equuleus
- T5551 (bug): Missing check for boot\_configuration\_complete raises error in vyos-save-config.py
- T5353 (bug): config-mgmt: normalize archive updates and commit log entries
- T3424 (default): PPPoE IA-PD doesn't work in VRF
- T2773 (feature): EIGRP support for VRF

### 3.2.169 2023-09-10

- T5565 (bug): Builds as vyos-999-timestamp instead of vyos-1.4-rolling-timestamp
- T5555 (bug): Fix timezone migrator (system 13-to-14)
- T5529 (bug): Missing symbolic link in linux-firmware package.

### 3.2.170 2023-09-09

- T5540 (bug): vyos-1x: Wrong VHT configuration for WiFi 802.11ac
- T5423 (bug): ipsec: no output for op-cmd "show vpn ike secrets"
- T3700 (feature): Support VLAN tunnel mapping of VLAN aware bridges

### 3.2.171 2023-09-08

- T5502 (bug): Firewall - wrong parser for inbound and/or outbound interface
- T5460 (feature): Firewall - remove config-trap
- T5450 (feature): Firewall interface group - Allow inverted matcher
- T4426 (default): Add arpwatch to the image
- T4356 (bug): DHCP v6 client only supports single interface configuration

### 3.2.172 2023-09-07

- T5510 (feature): Shrink imagesize and improve read performance by changing mksquashfs syntax

### 3.2.173 2023-09-06

- T5542 (bug): ipoe-server: external-dhcp(dhcp-relay) not woking / not implemented
- T5548 (bug): HAProxy renders timeouts incorrectly
- T5544 (feature): Allow CAP\_SYS\_MODULE to be set on containers

### 3.2.174 2023-09-05

- T5524 (feature): Add config directory to liveCD
- T5519 (bug): Function `call` sometimes hangs
- T5508 (bug): Configuration Migration Fails to New Netfilter Firewall Syntax
- T5495 (feature): Enable snmp module also for frr/ldpd
- T2958 (bug): DHCP server doesn't work from a live CD
- T5428 (bug): dhcp: client renewal fails when running inside VRF

### 3.2.175 2023-09-04

- T5536 (bug): show dhcp client leases causes No module named 'vyos.validate'
- T5506 (bug): Container bridge interfaces do not have a link-local address

### 3.2.176 2023-09-03

- T5538 (bug): Change order within variable lb\_config\_tmpl to fit order of manpage and fix some typos
- T4612 (feature): Support arbitrary netmasks in firewall rules

### 3.2.177 2023-08-31

- T5190 (feature): Cloud-Init cannot fetch Meta-data on machines where the main Ethernet interface is not eth0
- T4895 (bug): Tag nodes are overwritten when configured by Cloud-Init from User-Data
- T4776 (bug): NVME storage is not detected properly during installation
- T5531 (feature): Containers add label option
- T5525 (default): Change dev.packages.vyos.net repo to rolling-packages.vyos.net  
vyos-build:current uses

### 3.2.178 2023-08-30

- T4933 (default): Malformed lines cause vyos.util.colon\_separated\_to\_dict fail with a nondescript error
- T4790 (bug): RADIUS login does not work if sum of timeouts more than 50s
- T4113 (bug): Incorrect GRUB configuration parsing
- T5520 (bug): Likely source of corruption on system update exposed by change in coreutils for Bookworm
- T4151 (feature): IPV6 local PBR Support
- T4485 (default): OpenVPN: Allow multiple CAs certificates

### 3.2.179 2023-08-29

- T3940 (bug): DHCP client does not remove IP address when stopped by the 02-vyos-stopdhclient hook
- T3713 (default): Create a meta-package for user utilities
- T3339 (bug): Cloud-Init domain search setting not applied
- T3577 (bug): Generating vpn x509 key pair fails with command not found

### 3.2.180 2023-08-28

- T4745 (bug): CLI TAB issue with values with '-' at the beginning in conf mode
- T5472 (bug): NAT redirect should not require port

### 3.2.181 2023-08-27

- T4759 (bug): domain-group on policy route not working
- T1097 (feature): Make firewall groups work everywhere that's appropriate

### 3.2.182 2023-08-26

- T5039 (bug): Can't add new local user
- T5023 (bug): PKI commit fails to update dependents
- T4512 (feature): enable-default-log on zone-policy
- T5003 (default): Upgrade base system to Debian 12 "Bookworm"

### 3.2.183 2023-08-25

- T5468 (feature): Remove unused manpages to free up space
- T5463 (feature): Containers allow publish IPv6 address port
- T4412 (bug): commit archive: reboot not working with sftp
- T3702 (feature): Policy: Allow routing by fwmark
- T3536 (default): Unable to list all available routes

### 3.2.184 2023-08-24

- T5448 (feature): Add service zabbix-agent
- T5006 (bug): Http api segfault with concurrent requests
- T5505 (feature): system: zebra route-map is not removed from FRR
- T5305 (bug): REST API configure operation should not be defined as async
- T4292 (feature): Rewrite vyatta-save-config.pl to Python

### 3.2.185 2023-08-23

- T5478 (bug): Cannot configure resolver-cache options for firewall
- T5466 (feature): L3VPN - label allocation mode
- T5453 (bug): Fix nat66 - broken after load-balance was introduced in nat
- T5446 (bug): bgp: validity check for bestpath med option
- T5500 (feature): Minor fixes to configtree render

- [T5469](#) (default): Incorrect dependency set in the openvpn-dco package when building VyOS for arm64
- [T5387](#) (feature): dhcp6c: add a no release option
- [T5491](#) (feature): Hostapd - AP-Mode - allow white-/blacklisting of Clients
- [T4889](#) (default): Add nftables NAT REDIRECT [to localhost] to CLI

### 3.2.186 2023-08-22

- [T5407](#) (bug): Static routes pointed to container networks fail to persist after reboot

### 3.2.187 2023-08-20

- [T5470](#) (bug): wlan: can not disable interface if SSID is not configured

### 3.2.188 2023-08-18

- [T5488](#) (bug): System conntrack ignore does not take any effect

### 3.2.189 2023-08-17

- [T4202](#) (bug): NFT: Zone policies fail to apply when "l2tp+" is in the interface list
- [T5409](#) (feature): Add 'set interfaces wireguard wgX threaded'
- [T5476](#) (feature): netplug: replace Perl helper scripts with a Python equivalent
- [T5223](#) (bug): tunnel key doesn't clear
- [T5490](#) (feature): login: add missing regex for home directory and radius server key

### 3.2.190 2023-08-16

- [T5483](#) (bug): Residual dhcp-server test file causing zabbix-agent smoketest to fail

### 3.2.191 2023-08-15

- [T5293](#) (feature): Support for Floating Rules (Global Firewall-Rules that are automatically applied before all other Zone Rules)
- [T5273](#) (default): Add op mode commands for displaying certificate details and fingerprints
- [T5270](#) (default): Make OpenVPN `tls dh-params` optional

### 3.2.192 2023-08-14

- T5477 (bug): op-mode pki.py should use Config for defaults
- T5461 (feature): Improve rootfs directory variable
- T5457 (feature): Add environmental variable pointing to current rootfs directory
- T5440 (bug): Restore pre/postconfig scripts if user deleted them

### 3.2.193 2023-08-12

- T5467 (bug): ospf(v3): removing an interface from the OSPF process does not clear FRR configuration

### 3.2.194 2023-08-11

- T5465 (feature): adjust-mss: config migration fails if applied to a VLAN or Q-in-Q interface
- T2665 (bug): vyos.xml.defaults for tag nodes
- T5434 (enhancement): Replace remaining calls of vyos.xml library
- T5319 (enhancement): Remove remaining workarounds for incorrect defaults
- T5464 (feature): ipv6: add support for per-interface dad (duplicate address detection) setting

### 3.2.195 2023-08-10

- T5416 (bug): Ignoring "ipsec match-none" for firewall
- T5329 (bug): Wireguard interface as GRE tunnel source causes configuration error on boot

### 3.2.196 2023-08-09

- T5452 (bug): Uncaught error in generate\_cache during vyos-1x build
- T5443 (enhancement): Add merge\_defaults as Config method
- T5435 (enhancement): Expose utility function for default values at path

### 3.2.197 2023-08-07

- T5406 (bug): "update webproxy blacklists" fails when vrf is being configured
- T5302 (bug): QoS class with multiple matches generates one filter rule but expects several rules
- T5266 (bug): QoS- HTB error when match with a dscp parameter for queue-type 'priority'
- T5071 (bug): QOS-Rewrite: DSCP match missing

### 3.2.198 2023-08-06

- T5420 (feature): nftables - upgrade to latest 1.0.8
- T5445 (feature): dyndns: add possibility to specify update interval (timeout)

### 3.2.199 2023-08-05

- T5291 (bug): vyatta-cfg-cmd-wrapper missing `${vyos_libexec_dir}` variable
- T5290 (bug): Failing commits for SR-IOV interfaces using ixgbevf driver due to change speed/duplex settings
- T5439 (bug): Upgrade to FRR version 9.0 added new daemons which must be adjusted

### 3.2.200 2023-08-04

- T5427 (bug): Change migration script len arguments checking

### 3.2.201 2023-08-03

- T5301 (bug): NTP: chrony only allows one bind address
- T5154 (bug): Chrony - multiple listen addresses

### 3.2.202 2023-08-02

- T5374 (feature): Ability to set 24-hour time format
- T5350 (bug): Confusing warning message when committing VRRP config
- T5430 (bug): bridge: vxlan interfaces are not listed as bridgable in completion helpers
- T5429 (bug): vxlan: source-interface is not honored and throws config error
- T5415 (feature): Upgrade FRR to version 9.0
- T5422 (feature): Support LXD Agent

### 3.2.203 2023-08-01

- T5399 (bug): "show ntp" fails when vrf is being configured
- T5346 (bug): MPLS sysctl not persistent for L2TP interfaces
- T5343 (feature): BGP peer group VPNv4 & VPNv6 Address Family Support
- T5339 (feature): Geneve interface - option to use IPv4 as inner protocol
- T5335 (bug): ISIS: error when loading config from file

### 3.2.204 2023-07-31

- T5421 (feature): Add arg to completion helper 'list\_interfaces' to filter out vlan subinterfaces

### 3.2.205 2023-07-29

- T5403 (feature): Add support for extending xml cache

### 3.2.206 2023-07-28

- T4602 (bug): DHCP `ping-check` enabled by default
- T5411 (feature): Remove old background monitoring implementation
- T5317 (enhancement): configtree: remove mutable references
- T5316 (enhancement): configtree: use a single pass of the diff algorithm

### 3.2.207 2023-07-27

- T5368 (feature): FastNetmon service ids ddos-protection add support sflow mode

### 3.2.208 2023-07-26

- T5398 (bug): FRR mangles container network interface names
- T5365 (bug): Container systemd units require authentication
- T4974 (feature): OpenVPN- Data Channel Offload(DCO)

### 3.2.209 2023-07-25

- T5377 (feature): ospf: add graceful restart FRR feature (RFC 3623)

### 3.2.210 2023-07-21

- T5373 (bug): LLDP seems to be running even if its disabled on all interfaces
- T5328 (default): bgp: Incorrect warning showed for address-family configured with neighbor as interface
- T5363 (bug): Bash history file does not exists after reboot and any other file in home directory
- T5385 (bug): reference\_tree: catch parse error on non-transcluded files
- T5361 (bug): "monitor log" behaves like "show log"

### 3.2.211 2023-07-20

- T5362 (bug): ``set high-availability vrrp global-parameters version 3`` seems to have no effect
- T5355 (bug): IPsec: OP cmd : "show vpn ike sa" does not show output
- T5330 (enhancement): Keep track of source of config dict value when merging defaults
- T4497 (feature): ping cannot force ipv4 or ipv6
- T4288 (bug): IPsec tunnel will break when ESP timeout

### 3.2.212 2023-07-19

- T5340 (bug): SNMP and VRF
- T5059 (feature): add 'disable' option to DHCP relay config

### 3.2.213 2023-07-17

- T2051 (bug): Throughput anomalies

### 3.2.214 2023-07-16

- T141 (feature): TACACS+ Support

### 3.2.215 2023-07-15

- T5341 (feature): Improve CLI for high-availability virtual-server to work with multiple ports

### 3.2.216 2023-07-14

- T5358 (bug): 99-ipsec-dhclient-hook prevents DHCP stateless routes from being installed in VRF table
- T4376 (bug): DNAT with multiwan and policy routing, incoming connections only work on primary interface
- T305 (default): loadbalancing does not work with one pppoe connection and another connection of either dhcp or static

### 3.2.217 2023-07-13

- T4713 (bug): `vyos@vyos:~$ show nat destination rules` | doesn't work
- T2315 (feature): Ability to have right address-family for BGP peers.

### 3.2.218 2023-07-12

- T5347 (bug): Compare commit revision bug
- T5161 (default): BFD Static Route Monitoring
- T5105 (bug): DHCP Server - Wrong error message
- T4927 (bug): Need to change restart to reload-or-restart in Webproxy module
- T3835 (bug): vyos router 1.2.7 snmp Dos bug
- T5352 (default): Fix missing dependency for netavark
- T4959 (feature): Add container registry authentication config for containers

### 3.2.219 2023-07-11

- T5314 (bug): QOS Default classes are not configured with correct qdisc
- T4862 (bug): webproxy domain-block does not work
- T4844 (bug): Incorrect permissions of the safeguard DB directory
- T4815 (bug): Fix various name server config issues
- T4810 (bug): Op-mode show/monitor log pppoe interface does not show any logs
- T4758 (feature): Rewrite show dhcp server to vyos.opmode format
- T4262 (bug): install image doesn't respect chosen root partition size
- T3810 (bug): webproxy squidguard rules don't work properly after rewriting to python.
- T1928 (bug): Is the 'Welcome to VyOS' message when using SSH an information leak?
- T1877 (default): Feature Request: Allow NAT to use network and address groups
- T4813 (feature): L3VPN over GRE Tunnels
- T4943 (bug): Radius SSH login displays "permission denied" on 1.4 rolling release
- T4542 (default): route-map: "match prefix-len" incorrect behavior
- T4392 (default): Multiline login banner text reports error on commit

### 3.2.220 2023-07-10

- T5345 (bug): Error incorrectly raised in revised multi\_to\_list when tag node value name == tag node name
- T3578 (bug): Prefix-List(6) update cause empty prefix-list(6)
- T762 (feature): Include rulset in firewall

### 3.2.221 2023-07-06

- T5336 (feature): Add Swedish keyboard-layout

### 3.2.222 2023-07-04

- T5333 (bug): Policy base routing PBR generetes incorrect rules with name POSTROUTING
- T5081 (feature): ISIS and OSPF sincronization with IGP-LDP sync

### 3.2.223 2023-07-03

- T5295 (bug): QoS shaper incorrect rate limit the traffic
- T5334 (feature): ospf: add support for External Route Summarisation Type-5 and Type-7

### 3.2.224 2023-07-02

- T5332 (bug): Show policy route not working when no interface is configured

### 3.2.225 2023-07-01

- T5304 (feature): Containers add bind-propagation option rshared
- T5296 (bug): QoS class cannot calculate correctly the default bandwidth auto
- T5210 (bug): IPSec cosmetic bug for Warning vti inrerface
- T5277 (bug): Dhcpv6-relay does not start on boot

### 3.2.226 2023-06-30

- T5315 (feature): vrrp: add support for version 3
- T5283 (bug): IPoE server assigns network address
- T5313 (bug): UDP broadcast relay - missing verify() that relay interfaces have an IP address assigned

### 3.2.227 2023-06-29

- [T5320](#) (enhancement): Add warning when entering config mode after a boot configuration error

### 3.2.228 2023-06-28

- [T1237](#) (feature): Static Route Path Monitoring, failover

### 3.2.229 2023-06-26

- [T5159](#) (bug): DHCPv6-server leases op-command shows warning message even if configured

### 3.2.230 2023-06-25

- [T5240](#) (bug): Service router-advert failed to start radvd with more than 3 name-servers
- [T5312](#) (bug): Nonescaped special character in help text

### 3.2.231 2023-06-24

- [T5303](#) (bug): Rsyslog.service is not working
- [T5298](#) (bug): Add RFKILL support into kernel.
- [T5308](#) (enhancement): Remove workarounds for incorrect defaults in get\_interface\_dict
- [T5228](#) (enhancement): Simplify get\_config\_dict and add argument with\_defaults
- [T5310](#) (bug): Need some help troubleshooting NIC detection.

### 3.2.232 2023-06-22

- [T5297](#) (default): Utility function to check if config under node has been changed between revisions

### 3.2.233 2023-06-20

- [T5300](#) (bug): verification of port availability can return false negative on boot
- [T5248](#) (feature): Ability to load config via API in JSON format

### 3.2.234 2023-06-19

- T5281 (feature): Add kernel options for vhost-net
- T5072 (default): QoS-Rewrite: protocol name used literally
- T4969 (bug): QoS Policy - Unable to set class match mark number

### 3.2.235 2023-06-18

- T5256 (bug): QoS expects protocol number but not protocol name

### 3.2.236 2023-06-13

- T5258 (bug): git Actions use ubuntu-22.04 instead of deprecated ubuntu-18.04 for PR conflicts checker
- T5222 (feature): Add load-balancing reverse-proxy based on haproxy
- T5213 (feature): Accel-ppp sending accounting interim updates acct-interim-interval option
- T5171 (feature): Use XML for conf-mode "load-balancing wan" instead of legacy templates

### 3.2.237 2023-06-12

- T5282 (bug): Poweroff now does not work
- T5264 (feature): Add Mellanox Technologies firmware flash module mlxfw to kernel
- T5286 (feature): Remove XDP support

### 3.2.238 2023-06-10

- T5231 (feature): Add op-mode for load-balancing reverse-proxy

### 3.2.239 2023-06-09

- T5253 (bug): MPLS config removed at boot when wireguard interfaces present

### 3.2.240 2023-06-05

- T5259 (bug): Openconnect cannot pass migration 1-to-2

### 3.2.241 2023-06-02

- [T5252](#) (bug): Route distinguisher and route targets changing upon adding interface to new VRF
- [T5251](#) (bug): Uncaught errors for functions delete/delete\_value in Python module configtree.py

### 3.2.242 2023-06-01

- [T5127](#) (bug): VPNv4/VPNv6 routes are not reinstalled following link flap

### 3.2.243 2023-05-28

- [T5244](#) (feature): dropbear: update to 2022.83
- [T5242](#) (feature): interfaces: smoketest: automatically detect "capabilities"
- [T5234](#) (feature): Add bash identifier for given VRF instance

### 3.2.244 2023-05-25

- [T5237](#) (feature): interfaces virtual-ethernet - Extend capabilities of Vlans/QinQ
- [T4686](#) (feature): Provides support for veth

### 3.2.245 2023-05-24

- [T4605](#) (feature): Firewall change default table names
- [T4550](#) (feature): router-advert: Add deprecate-prefix & decrement-lifetimes options

### 3.2.246 2023-05-23

- [T4916](#) (feature): Rewrite IPsec authentication

### 3.2.247 2023-05-22

- [T5214](#) (bug): PPPoE-server incorrect warning if a named pool is defined
- [T4977](#) (feature): Babel routing protocol support

### 3.2.248 2023-05-21

- [T4733](#) (default): Feature Request: dhcp server: add VRF support
- [T5218](#) (enhancement): Revise vyos xml lib for bug fixes and extensions

### 3.2.249 2023-05-17

- [T5226](#) (default): Deduplicate and standardize validators and constraints for hostname and IP address
- [T5225](#) (bug): BGP allowas-in unusable
- [T5208](#) (bug): Failed to start nvmmf-autoconnect.service during the boot

### 3.2.250 2023-05-16

- [T5194](#) (default): Add reference tree to vyoslx-config

### 3.2.251 2023-05-15

- [T3896](#) (feature): Extend ocserv support to allow for per-group configs

### 3.2.252 2023-05-12

- [T2778](#) (feature): Migrate "system syslog" to get\_config\_dict() to support new features
- [T2769](#) (feature): Add VRF support for syslog

### 3.2.253 2023-05-10

- [T5209](#) (bug): dhclient load-balancing exit hook 04-dhcp-wanlb returned non-zero exit status
- [T5065](#) (bug): Mixing `destination port xxx` and `destination group port-group yyy` in firewall rules doesn't work, but can be committed
- [T5060](#) (feature): add a VRRP 'maintenance mode'

### 3.2.254 2023-05-09

- [T5202](#) (bug): After removal load-balancing a pid remained which used in dhclient-exit-hooks

### 3.2.255 2023-05-06

- T5206 (bug): `ethtool.py:Ethtool.__init__` has always true conditional due to typo

### 3.2.256 2023-05-05

- T5082 (feature): container: switch to netavark network stack

### 3.2.257 2023-05-04

- T5193 (feature): Ability to specify NS records to specify NS servers for subdomains
- T3891 (bug): X550-T2/Possibly other X550/X540 cards no link on VyOS
- T5010 (bug): bgp: EVPN route-target not honored
- T5196 (feature): wwan: op-mode should inform user if there is no WWAN interface

### 3.2.258 2023-05-03

- T5163 (feature): Policy route-map add match source-protocol

### 3.2.259 2023-05-02

- T5042 (bug): Command 'show vpn ipsec remote-access' does not work

### 3.2.260 2023-04-27

- T5185 (bug): Static IPv6 route with blackhole fails
- T5175 (bug): http-api: error in MultiPart parser for FastAPI version `>= 0.91.0`
- T5183 (bug): IPv6 route6 problem
- T5181 (bug): Wrong dependencies or priorities for zebra vni vrf interfaces and bgpd
- T5128 (feature): Policy route - Allow wildcard interfaces
- T5055 (feature): Firewall - Add packet type matcher (pkttype)
- T5050 (feature): Firewall - Add options for logging packets
- T5037 (feature): Firewall - Add queue action
- T5176 (bug): http-api: update vyos-http-api-tools for FastAPI security vulnerability
- T5174 (bug): vrf: ensure no duplicate VNIs can be created
- T5123 (default): Display route originator in `show ospf table` command

### 3.2.261 2023-04-25

- [T5179](#) (bug): multi nodes defined in XML are not properly represented as list in `get_config_dict()`

### 3.2.262 2023-04-17

- [T5052](#) (bug): Error displaying dhcpv6 prefix delegation leases
- [T5150](#) (feature): Rework CLI definitions to apply route-maps between routing daemons and zebra/kernel
- [T3734](#) (bug): Move EVPN VRF up in FRR config

### 3.2.263 2023-04-13

- [T5152](#) (bug): Telegraf agent hostname isn't qualified
- [T4727](#) (feature): Add RADIUS rate limit support to PPTP server
- [T4939](#) (bug): VRRP command no-preempt not work as expected
- [T4791](#) (default): Consistent normalization of 'raw' output of op-mode scripts for CLI and API
- [T3608](#) (default): Standardize warnings from configure scripts

### 3.2.264 2023-04-11

- [T4924](#) (bug): Systemctl strongswan.service for some reason is not disabled
- [T4197](#) (bug): Vyos arm64-latest build issue with telegraf pkg
- [T4051](#) (bug): Connected routes strange / not working

### 3.2.265 2023-04-10

- [T5151](#) (bug): EAP-TLS TLSv1.0/1.1 regression after T5003
- [T5148](#) (bug): OpenVPN cannot start due to could not load plugin shared object / `openvpn-otp.so`
- [T5110](#) (bug): Show frr op-mode vtysh\_pam: Failed in account validation
- [T5078](#) (feature): VyOS BGP does not support 'show bgp neighbors \$NB filtered-routes'
- [T5070](#) (feature): show bgp nexthop unavailable in VRF
- [T5061](#) (bug): All containers restart on config change

### 3.2.266 2023-04-07

- T5149 (bug): op-mode openvpn should not raise error in case interface is disabled

### 3.2.267 2023-04-06

- T5147 (bug): Can't Commit with Container Network
- T5142 (feature): One of the requirements is to use a system auditing tool to monitor and log all security-relevant events.
- T5125 (feature): Add op-mode commands for hsflowd based sflow

### 3.2.268 2023-04-05

- T5145 (feature): Add maxsyslogins maximum number of all logins on system
- T5135 (default): Rewrite opennhrp script using vyos.ipsec library
- T4975 (bug): CLI does not work after cutting off the power or reset
- T5136 (bug): Possible config corruption on upgrade

### 3.2.269 2023-04-04

- T5141 (feature): Add numbers for dhclient-exit-hooks.d to enforce script order execution
- T5093 (bug): Command 'reset vpn ipsec-profile' doesn't work
- T4362 (bug): Wan Load Balancing - Can't create routing tables

### 3.2.270 2023-04-03

- T5139 (feature): IKE life-time should start from 0 for disable rekey
- T4173 (bug): Wan Load Balancing - Error on firewall NAT rules

### 3.2.271 2023-04-02

- T5134 (feature): Try if netavark networks can be moved to a VRF instance

### 3.2.272 2023-04-01

- T5047 (bug): Recreate only a specific container
- T5132 (default): Operational command "show isis vrf XXX route | neighbord" aren't working

### 3.2.273 2023-03-31

- T5129 (feature): Add AWS build flavour
- T5126 (feature): http-api: add 'allow-client' to restrict IP address of client connections

### 3.2.274 2023-03-30

- T5130 (bug): op-mode: drop remaining reference to obsoleted 'show\_interfaces.py'
- T4866 (feature): Rewrite show\_interfaces to standardized form
- T366 (bug): SNMP Query for BGP Tunnels Returns IPv4 Tunnels Only

### 3.2.275 2023-03-29

- T5100 (feature): Update FRR to 8.5
- T5094 (bug): FRR systemd logs unknow key LimitNOFILESoft
- T5085 (bug): ospfv3 route-map not applied in FRR configuration
- T5056 (bug): IPoE server vlan-mon is not working
- T5033 (bug): generate-public-key command fails for address with multiple public keys like GitHub
- T4876 (bug): mpls - LSP broken on FRR 8.4.1
- T5097 (bug): the operational command "show interfaces ethernet ethx" doesn't reflect a call to 'clear counters'
- T5089 (enhancement): Add unit test of config\_diff
- T5088 (enhancement): Add lexicographical-numeric compare function for vytree/configtree
- T5087 (enhancement): Add support for lexical ordering of nodes in config\_tree
- T4885 (feature): Rewrite 'clear interfaces counters' from Perl to Python
- T4846 (bug): L3VPN- network command doesn't install direct connected prefix

### 3.2.276 2023-03-28

- T5043 (feature): Need to create reset command for IKEv2 remote-access vpn connections

### 3.2.277 2023-03-27

- T5099 (feature): IPoE server add option 'next-pool' for named ip pools
- T5106 (feature): Extend generation of API client requests to configsession native functions and composite requests
- T5104 (bug): DHCP default route issues with static routes in VRFs
- T5079 (feature): xml: schema extension to support defaultValues on tagNodes
- T5114 (feature): bgp: implement new CLI commands introduced in FRR 8.5

### 3.2.278 2023-03-23

- T5108 (feature): Get rate limit for L2TP/PPTP/SSTP/IPoE in raw format
- T5086 (feature): Integrate hsflowd for sflow accounting
- T5107 (bug): Raise error in op-mode dns.py instead of calling exit

### 3.2.279 2023-03-22

- T5068 (feature): Generate op-mode API client requests along with schema generation

### 3.2.280 2023-03-21

- T5098 (feature): PPPoE client holdoff configuration
- T3694 (bug): Static routes not installed into kernel nor frr
- T5102 (feature): ospf: "redistribute babel" is always set

### 3.2.281 2023-03-20

- T5057 (bug): IPoE server incorrect interface regex
- T5095 (feature): Return list instead of dict for 'raw' output of op-mode openvpn

### 3.2.282 2023-03-19

- T4925 (feature): Need to add the possibility to configure Pseudo-Random Functions (PRF) in IKEv2

### 3.2.283 2023-03-17

- T5092 (bug): IPoE-server named pool must not rely on the authentication type
- T5091 (bug): IPoE server with RADIUS authentication does not verify radius configuration

### 3.2.284 2023-03-16

- T5073 (bug): IPoE-server interface option failed to parse
- T5063 (bug): IPoE-server ethX vlan must not be used with client-subnet
- T5058 (feature): Extend template filter range\_to\_regex
- T3083 (feature): Add feature event-handler
- T2516 (bug): vyos-container: cannot configure ethernet interface

### 3.2.285 2023-03-13

- T5074 (bug): Show IPSEC SA failed if remote access IKEv2 vpn is used.
- T4973 (bug): show dhcp server leases error for lease time 4294967295

### 3.2.286 2023-03-11

- T5076 (feature): CI/CD: Docker container is bloated by legacy and conflicting dependencies

### 3.2.287 2023-03-09

- T5066 (bug): Different GRE tunnel but same tunnel keys error
- T4952 (feature): Improve interface completion helper CLI experience

### 3.2.288 2023-03-08

- T4381 (default): OpenVPN: Add "Tunnel IP" column in "show openvpn server" operational command
- T4872 (bug): Op-mode show openvpn misses a case when parsing for tunnel IP

### 3.2.289 2023-03-07

- T2838 (bug): Ethernet device names changing, multiple hw-id being added
- T5051 (feature): Use Literal types to provide op-mode CLI choices and API enums
- T4900 (default): Cache intermediary results of get\_config\_diff in Config instance

### 3.2.290 2023-03-05

- T5040 (default): Generate API GraphQL schema on installation, rather than dynamically

### 3.2.291 2023-03-03

- T4625 (enhancement): Update ocerv to current revision (1.1.6)

### 3.2.292 2023-03-02

- T4967 (feature): Ability to set hostname for the container

### 3.2.293 2023-03-01

- T5015 (bug): Invalid format character error at hfsc class settings help text

### 3.2.294 2023-02-28

- T5029 (feature): Nginx change default root directory and fix regex
- T5025 (bug): Time-zone validation failed
- T4955 (bug): Openconnect radiusclient.conf generating with extra authserver
- T4843 (feature): Command-line arguments in container config
- T4219 (feature): support incoming-interface (iif) in local PBR
- T3903 (bug): Containers: after command "reboot" the host system will reboot after 1.5 minutes

### 3.2.295 2023-02-27

- T5028 (feature): Add package exfatprogs to VyOS
- T4985 (bug): reset vpn ipsec-peer command with peer name does not work

### 3.2.296 2023-02-26

- T4979 (feature): Add API request 'show\_user\_info' for UI

### 3.2.297 2023-02-25

- T5008 (bug): MACsec CKN of 32 chars is not allowed in CLI, but works fine
- T5007 (bug): Interface multicast setting is invalid
- T5027 (bug): OpenVPN options and site-to-site cannot pass smoketest
- T4978 (bug): KeyError: 'memory' container\_config['memory'] on upgrading to 1.4-rolling-202302041536
- T5034 (bug): Migrate multicast CLI node to valueLess

- T4948 (feature): pppoe: add CLI option to allow definition of host-uniq flag

### 3.2.298 2023-02-24

- T5030 (bug): HTTPS-API delete key without id error

### 3.2.299 2023-02-23

- T5013 (feature): Extend accelppp.py op-mode to get subnet start stop info from config
- T5002 (feature): Add uk (United Kingdom) keymap

### 3.2.300 2023-02-22

- T5024 (bug): check-qemu-install VM is not shutdown the first time
- T5011 (bug): Some interface drivers don't support min\_mtu and max\_mtu and verify\_mtu check should be skipped

### 3.2.301 2023-02-21

- T5021 (bug): IPsec SA is closed before negotiating a new one or it is negotiated on every second if big life-time is set in swanctl.conf
- T5020 (feature): Extend openvpn.py op-mode to get a list of configured clients

### 3.2.302 2023-02-20

- T5005 (feature): Skip user authentication for PPPoE Server with noauth option

### 3.2.303 2023-02-16

- T4971 (feature): Radius attribute "Framed-Pool" for PPPoE

### 3.2.304 2023-02-15

- T4991 (bug): Restore path level information to compare output

### 3.2.305 2023-02-14

- T4968 (bug): VPN IPsec check dpd and close action for empty values
- T1993 (feature): Extended pppoe rate-limiter

### 3.2.306 2023-02-13

- T4905 (feature): Convert show nhrp tunnel to tabulate format
- T4153 (bug): Monitor bandwidth-test initiate not working

### 3.2.307 2023-02-12

- T4998 (bug): pppoe username validation too restrictive (regression)

### 3.2.308 2023-02-11

- T2603 (feature): pppoe-server: reduce min MTU

### 3.2.309 2023-02-10

- T4857 (feature): SNMP - Implement FRR SNMP recommendations
- T4995 (feature): pppoe, wwan and sstp-client - rename user -> username on authentication

### 3.2.310 2023-02-07

- T4980 (bug): chrony not listening as a server
- T4868 (bug): L2TP ppp-options ipv6 does not work without ipv6 pool but should
- T4117 (bug): Does not possible to configure PoD/CoA for L2TP vpn

### 3.2.311 2023-02-01

- T4970 (default): pin OCaml pcre package to avoid JIT support

### 3.2.312 2023-01-31

- T4964 (bug): FRR bgp address-family l2vpn-evpn route-target export/import not working
- T4780 (feature): Firewall - Add interface group
- T4157 (default): Add jinja2 to pip test requirements

### 3.2.313 2023-01-30

- T4958 (feature): Add OpenConnect RADIUS Accounting support
- T4954 (bug): DNS cannot be configured via Network-Config v1 received from ConfigDrive / Cloud-Init
- T4118 (default): IPsec syntax overhaul

### 3.2.314 2023-01-29

- T4965 (default): empty description in firewall group causes configuration error on migration

### 3.2.315 2023-01-28

- T4961 (bug): Uncaught configtree error allows ntp migration 1-to-2 to fail silently on config.boot.default

### 3.2.316 2023-01-27

- T4960 (bug): Bugs in `cc\_vyos.py` code (Cloud-Init)

### 3.2.317 2023-01-26

- T4886 (feature): Firewall and Policy - Add connection mark
- T4957 (bug): config-mgmt should not attempt to archive config at boot
- T4962 (bug): Fix typo in regex in vyos.config\_mgmt compare function
- T4912 (default): Rewrite the IGMP op mode in the new style

### 3.2.318 2023-01-25

- T4941 (bug): Accel-ppp IPoE incompatibility with kernel 6.1

### 3.2.319 2023-01-24

- T4947 (feature): Support mounting container volumes as ro or rw

### 3.2.320 2023-01-23

- T4798 (default): Migrate the file-exists validator away from Python
- T4683 (enhancement): Add kitty-terminfo package to build
- T4953 (bug): Remove convert\_kwargs\_to\_snake\_case decorator in dynamic generation of GraphQL resolvers
- T4875 (default): Replace Python validator 'interface-name' to avoid Python startup cost
- T4664 (bug): Add validation to reject whitespace in tag node value names

### 3.2.321 2023-01-22

- T4906 (bug): ipsec connections shows only one connection as up

### 3.2.322 2023-01-21

- T4799 (bug): PowerDNS >= 4.7 does not get reloaded by vyos-hostsd
- T4878 (bug): Any interface bonding changes cause interface flapping
- T4387 (default): Create additional smoketests for multiwan PBR & load-balanced configurations

### 3.2.323 2023-01-20

- T4551 (bug): IPsec rekeying collisions bug
- T4942 (feature): Rewrite vyatta-config-mgmt to Python/XML

### 3.2.324 2023-01-17

- T4938 (bug): Interface input ifb does not work
- T4902 (bug): snmpd: exclude container storage from monitoring
- T4140 (bug): Lack of SNMP IANA mibs

### 3.2.325 2023-01-15

- T4832 (feature): dhcp: Add IPv6-only dhcp option support (RFC 8925)
- T4937 (feature): ocserv: upgrade package to version 1.1.6
- T4918 (bug): Odd show interface behavior
- T3008 (feature): Migrate from ntpd to chronyd

### 3.2.326 2023-01-13

- T4911 (default): Rewrite the LLDP op mode in the new format
- T4928 (feature): Upgrade Linux Kernel to 6.1.y (2022 LTS edition)

### 3.2.327 2023-01-12

- T4934 (bug): ospf: Fix inter-area route summarization
- T4929 (feature): Update Intel QAT drivers to 4.20.0-00001

### 3.2.328 2023-01-10

- T4880 (feature): Expose 'add/delete container image' in HTTP-API

### 3.2.329 2023-01-09

- T4922 (feature): Add ssh-client source-interface CLI option
- T4524 (bug): Squid webproxy not working properly

### 3.2.330 2023-01-08

- T4920 (bug): ospf: Fix `passive-interface default` option

### 3.2.331 2023-01-07

- T4884 (bug): Missing a community6 in snmpd config

### 3.2.332 2023-01-05

- T4904 (feature): Allow multiple ports for high-availability virtual-server
- T4789 (feature): Ability to get L2TP/PPTP/SSTP sessions info in a machine readable format
- T3937 (default): Rewrite "show system memory" in Python to make it usable as a library function

### 3.2.333 2023-01-04

- T4848 (bug): Minor bug in OpenConnect server with default route
- T4656 (feature): Support the listen-host config field of openconnect server

### 3.2.334 2023-01-03

- T4907 (bug): nat source translations couldn't show metrics

### 3.2.335 2023-01-02

- T4893 (feature): l2tp add ppp-options IPv6 interface identifier
- T4717 (feature): Connect to console server by name
- T725 (feature): Cake and FQ-PIE

### 3.2.336 2022-12-31

- T4898 (feature): Add mtu config option for dummy interfaces

### 3.2.337 2022-12-30

- T4834 (bug): Limit container network name to 15 characters
- T4901 (bug): Update Podman to v4.3.1
- T4899 (bug): Podman systemd services not being installed correctly

### 3.2.338 2022-12-28

- T4593 (feature): Upgrade strongswan to 5.9.8

### 3.2.339 2022-12-26

- T4511 (bug): IPv6 DNS lookup
- T4809 (feature): radvd: Allow use of AdvRASrcAddress

### 3.2.340 2022-12-25

- T3579 (feature): Rewrite vyatta-contrack in new XML and Python flavour

### 3.2.341 2022-12-24

- T4890 (bug): show conntrack table ipv4 fail
- T4879 (bug): IPSec migration failed with missing remote-id
- T4870 (feature): Containers switch to using overlay driver for podman storage

### 3.2.342 2022-12-23

- T4792 (feature): Add SSTP VPN client

### 3.2.343 2022-12-21

- T4887 (bug): Schema generation from op-mode functions should set default 'false' on boolean arguments

### 3.2.344 2022-12-18

- T4882 (bug): Missing ICMPv6 type names in firewall configuration

### 3.2.345 2022-12-15

- T4671 (bug): linux-firmware package is missing symlinks defined in WHENCE file

### 3.2.346 2022-12-14

- T4881 (bug): Return `opmode.Error` on `openconnect.py show_sessions`

### 3.2.347 2022-12-12

- T4861 (feature): Openconnect restart on adding users - Aborts all active connections

### 3.2.348 2022-12-09

- T4865 (bug): container impossible to generate local image from a file if it requires install some pkgs

### 3.2.349 2022-12-05

- T4860 (bug): Openconnect server incorrect unconfigured check
- T4804 (bug): PPPoE server incorrect unconfigured check
- T4854 (feature): BGP-route reflector allows to apply route-maps

### 3.2.350 2022-12-04

- T4825 (feature): interfaces `veth/veth-pairs -standalone` used
- T4805 (bug): PPPoE server does not restart service if pool was changed

### 3.2.351 2022-12-02

- T4830 (bug): nat66 - Error in port translation rules
- T4859 (bug): Correct calling of config mode script dependencies from `http-api.py`
- T4820 (enhancement): Support for inter-config-mode script dependencies
- T4858 (bug): L3VPN- Route Distinguisher notations
- T1024 (feature): Policy Based Routing by DSCP

### 3.2.352 2022-12-01

- T4841 (feature): add fan control
- T4847 (bug): Correct calling of config mode script dependencies from pki.py

### 3.2.353 2022-11-29

- T4842 (bug): Routing config broken if mpls config exists
- T4845 (default): Add smoketest to detect cycles in config-mode script dependency calls

### 3.2.354 2022-11-27

- T4739 (feature): ISIS and OSPF segment routing being refactored

### 3.2.355 2022-11-24

- T4794 (bug): show firewall name <name> - Can't use .items() on a list
- T4714 (feature): Delete unused ipset from the filecaps
- T3541 (bug): Route Map large community set additive is missing

### 3.2.356 2022-11-23

- T4836 (feature): Kernel: enable new features like switchdev, ESP in TCP and HSR
- T4835 (bug): SNMPD configuration incorrect for IPv6
- T4819 (feature): Allow printing Warning messages in multiple lines with \n
- T4807 (feature): Need to fix traceroute help completion
- T4660 (feature): Reorganize route map set community CLI
- T4526 (bug): keepalived-fifo.py unable to load config
- T4793 (feature): Create warning message about disable-route-autoinstall when ipsec vti is used
- T4492 (bug): Incorrect list of neighbors in help for "show bgp vrf VRF neighbors"
- T4496 (feature): ping vrf help does not list VRFs

### 3.2.357 2022-11-22

- T4823 (bug): swanctl.conf is broken when ipsec site-to-site peer set.
- T4706 (bug): NAT and NAT66 issues
- T4670 (feature): policy route - Update matching criteria

### 3.2.358 2022-11-21

- T4812 (feature): IPsec ability to show all configured connections
- T4829 (default): Tunnel argument to 'reset\_peer' in ipsec.py should have type hint Optional

### 3.2.359 2022-11-20

- T4827 (bug): route-map issues , not load configuration FRR

### 3.2.360 2022-11-19

- T4826 (bug): Wrong key type is used for SSH SK public keys
- T4720 (feature): Ability to configure SSH HostKeyAlgorithms
- T4828 (default): Raise appropriate op-mode errors in ipsec.py 'reset\_peer'

### 3.2.361 2022-11-18

- T4821 (bug): Correct calling of config mode script dependencies from firewall.py

### 3.2.362 2022-11-17

- T4750 (feature): Support of higher level SSH keys (sk-ssh-ed25519)

### 3.2.363 2022-11-15

- T4808 (feature): Add details of configtree operations to migration log

### 3.2.364 2022-11-12

- T4814 (bug): Regression in bundled powerdns version

### 3.2.365 2022-11-09

- T4800 (bug): undefined var includes\_chroot\_dir in build-vyos-image

### 3.2.366 2022-11-08

- T4771 (feature): Rewrite protocol BGP op-mode to vyos.opmode format
- T4806 (default): Update FRR to 8.4 in 1.4 version

### 3.2.367 2022-11-06

- T4803 (bug): The header 'Authorization' needs to be explicitly allowed in http-api CORS middleware

### 3.2.368 2022-11-05

- T4802 (feature): Ability to define per container shared-memory size

### 3.2.369 2022-11-01

- T4764 (bug): NAT tables vyos\_nat and vyos\_static\_nat not deleting after deleting nat
- T4177 (bug): Strip-private doesn't work for service monitoring

### 3.2.370 2022-10-31

- T4786 (feature): Add package python3-pyhumps
- T1875 (feature): Add the ability to use network address as BGP neighbor (bgp listen range)
- T4785 (feature): snmp: Allow !, @, \* and # in community name
- T4787 (feature): ipsec: add support for road-warrior/remote-access RADIUS timeout

### 3.2.371 2022-10-29

- T4783 (default): Add support for stunnel
- T4784 (feature): Add description node for static route/route6 tagNodes

### 3.2.372 2022-10-28

- T4291 (default): Consolidate component version read/write functions

### 3.2.373 2022-10-27

- T4763 (feature): Change XML for Show nat destination statistics
- T4762 (bug): Show nat rules with empty rules incorrect error
- T4778 (bug): Raise error UnconfiguredSubsystem if op-mode ipsec.py fails initialization

### 3.2.374 2022-10-26

- T4773 (default): Add camel\_case to snake\_case conversion utility

### 3.2.375 2022-10-25

- T4574 (default): Add token based authentication to GraphQL API

### 3.2.376 2022-10-24

- T4772 (default): Return list of dicts in 'raw' output of route.py instead of dict with redundant information

### 3.2.377 2022-10-23

- T3723 (bug): op-mode IPsec show vpn ipsec sa output with underscores

### 3.2.378 2022-10-21

- T4768 (default): Change name of api child node from 'gql' to 'graphql'

### 3.2.379 2022-10-18

- T4684 (feature): Rewrite show ip route by protocol to vyos.opmode format
- T4533 (bug): Radius clients don't have simple permissions
- T4753 (enhancement): Extend automatic generation of schema to query SystemStatus

### 3.2.380 2022-10-17

- T4725 (bug): Unable to reset vpn IPsec peer

### 3.2.381 2022-10-14

- T4672 (bug): RADIUS server disable does not work
- T4749 (enhancement): Use config\_dict for conf\_mode http-api.py

### 3.2.382 2022-10-13

- T4746 (bug): Monitoring nft. table vyos\_filter by default does not exist but telegraf checks this table
- T4744 (bug): BGP directly connected neighbors don't compatible with ebgp-multihop
- T4716 (feature): SSH ability to configure RekeyLimit
- T4343 (default): Expose powerdns network-timeout for service dns forwarding
- T4312 (bug): Telegraf configuration doesn't accept IPs for URL

- T4274 (default): Extend OpenConnect RADIUS Timeout to Permit 2FA Entry

### 3.2.383 2022-10-12

- T4747 (bug): Monitoring influxdb template input exec plugin does not work
- T4740 (bug): Show conntrack table ipv6 fail
- T4730 (bug): Conntrack-sync error - listen-address is not the correct type in config as it should be

### 3.2.384 2022-10-11

- T4742 (bug): Autocomplete in policy route rule x set table / does not show the tables created in the static protocols
- T4741 (bug): set firewall zone Local local-zone failed
- T4680 (bug): Telegraf prometheus-client listen-address invalid format

### 3.2.385 2022-10-10

- T538 (feature): Support for network mapping in NAT

### 3.2.386 2022-10-09

- T4738 (enhancement): Extend automatic generation of schema definition files to native configsession functions; use single resolver/directive

### 3.2.387 2022-10-08

- T4707 (feature): Enable OSPF segment routing

### 3.2.388 2022-10-07

- T4736 (bug): Error on JSON output of API query ShowConfig

### 3.2.389 2022-10-04

- T4708 (bug): 'show nat destination rules' throwing an error
- T4700 (feature): Firewall - Add interface match criteria
- T4699 (feature): Firewall - Add jump action - Add return action
- T4651 (feature): Firewall - Add options to match packet size
- T4702 (bug): Wireguard peers configuration is not synchronized with CLI
- T4685 (bug): Interface does not exist on boot when used as inbound-interface for local policy route
- T4652 (feature): Upgrade PowerDNS recursor to 4.7 series

- T4582 (default): Router-advert: Preferred lifetime cannot equal valid lifetime in PIOs

### 3.2.390 2022-09-29

- T4715 (feature): Auto logout user after a period of inactivity
- T4697 (bug): policy route: Generating ConfigError failes when tcp flag is missing on set tcp-mss rule commit

### 3.2.391 2022-09-27

- T4711 (feature): Ability to terminate user TTY and PTS sessions
- T4557 (feature): fastnetmon: allow configure limits per protocol (tcp, udp, icmp)

### 3.2.392 2022-09-21

- T4678 (feature): Rewrite service ipoe-server to get\_config\_dict
- T4703 (feature): accel-ppp: combine vlan-id and vlan-range into single CLI node

### 3.2.393 2022-09-20

- T4693 (bug): ISIS segment routing was broken...

### 3.2.394 2022-09-17

- T4666 (bug): EAP-TLS no longer allows TLSv1.0 after T4537, T4584
- T4665 (bug): Keepalived cannot use same VRID for VRRPv2 and VRRPv3

### 3.2.395 2022-09-16

- T4698 (enhancment): Drop validator name="range" and replace it with numeric
- T4695 (feature): Add 'es' and 'jp106' keymap option keyboard-layout
- T4669 (enhancment): Extend numeric.ml for inversion of values and range values

### 3.2.396 2022-09-15

- T4679 (bug): OpenVPN site-to-site incorrect check for IPv6 local and remote address
- T4691 (feature): Upgrade Linux Kernel to latest 5.15.y train
- T4630 (bug): Prevent attempts to use the same interface as a source interface for pseudo-ethernet and MACsec at the same time
- T4696 (default): Extend bgp parameters for bgp bestpath peer-type multipath-relax

### 3.2.397 2022-09-12

- T4617 (feature): VRF specification is needed for telegraf prometheus-client listen-address <address>
- T4690 (bug): Update GraphQL resolver for 'SystemStatus' following changes to 'show\_uptime' op-mode script
- T4647 (feature): Add Google Virtual NIC (gVNIC) support
- T4170 (feature): Rename "policy ipv6-route" -> "policy route6"

### 3.2.398 2022-09-09

- T4682 (feature): Rewrite 'show system storage' in standardized format
- T4681 (feature): Complete standardization of show\_uptime.py

### 3.2.399 2022-09-06

- T4640 (enhancement): Integrate op-mode exception hierarchy into API
- T4597 (bug): Check bind port before assign service HTTPS API and openconnect
- T4674 (bug): API should show op-mode error message, if present
- T4673 (bug): op-mode bridge.py should raise error on show\_fdb for nonexistent bridge interface

### 3.2.400 2022-09-05

- T4668 (bug): Adding/removing members from bond doesn't work/results in incorrect interface state
- T4663 (bug): Interface pseudo-ethernet does not change mode
- T4655 (bug): Firewall in 1.4 sets the default action 'accept' instead of 'drop'
- T4628 (bug): ConfigTree() throws ValueError() if tagNode contains whitespaces

### 3.2.401 2022-09-01

- T4606 (bug): monitor nat destination translation shows missing script
- T4435 (bug): Policy route and firewall - error when using undefined group
- T4147 (bug): New Firewall Implementation - proposed changes on group implementation

### 3.2.402 2022-08-31

- T4650 (feature): Rewire show nat translation to vyos.opmode format
- T4644 (bug): Check bind port before assign vpn sstp
- T4643 (bug): Smoketest exclude either sstp or openconnect from pki-misc default listen port
- T4569 (feature): Rewrite show bridge to new format
- T4547 (bug): Show vpn ipsec sa show unexpected prefix 'B' in packets
- T4367 (bug): NAT - Config tmp file not available

### 3.2.403 2022-08-29

- T4645 (bug): show nat source statistics lack argument --family
- T4634 (bug): Bgp neighbor disable-connected-check does not work
- T4631 (feature): Add port and protocol to nat66
- T4623 (feature): Add show conntrack statistics
- T4595 (bug): DPD interval and timeout do not work in DMVPN
- T4594 (feature): Rewrite op-mode IPsec to vyos.opmode format
- T4508 (bug): Problem with values of the same environment in different event handlers
- T4653 (bug): Interface offload options are not applied correctly
- T4546 (bug): Does not connect Cisco spoke to VyOS hub.
- T4061 (default): Add util function to check for completion of boot config
- T4654 (bug): RPKI cache incorrect description
- T4572 (bug): Add an option to force interface MTU to the value received from DHCP

### 3.2.404 2022-08-26

- T4642 (bug): proxy: hyphen not allowed in proxy URL

### 3.2.405 2022-08-25

- T4626 (bug): Error showing nat66 source and destination
- T4622 (feature): Firewall allow drop packets by TCP MSS size

### 3.2.406 2022-08-24

- T4641 (bug): prefix-list allows ipv6 prefix as input
- T4633 (feature): Change keepalived to v2.2.7

### 3.2.407 2022-08-23

- T4618 (bug): Traffic policy not set on virtual interfaces
- T4538 (bug): Macsec does not work correctly when the interface status changes.

### 3.2.408 2022-08-22

- T4089 (bug): Show nat destination rules shows ip address instead of interface 'any'
- T4632 (bug): VLAN-aware bridge not working
- T4637 (feature): Upgrade to podman 4.2.0

### 3.2.409 2022-08-20

- T4596 (bug): "show openconnect-server sessions" command does not work in the openconnect module

### 3.2.410 2022-08-19

- T4620 (bug): UPnP does not work due to incorrect template
- T4619 (bug): Static arp is not set if another entry is present
- T4611 (bug): UPnP rule IP should be a prefix instead of an address
- T4614 (feature): OpenConnect split-dns directive

### 3.2.411 2022-08-18

- T4613 (bug): UPnP configuration without listen option fail
- T4570 (bug): Exception when trying to set up VXLAN over Wireguard

### 3.2.412 2022-08-17

- T4598 (feature): nat66 - Add exclude options
- T4480 (default): add an ability to configure squid acl safe ports and acl ssl safe ports

### 3.2.413 2022-08-16

- T4592 (bug): macsec: can not create two interfaces using the same source-interface
- T4584 (bug): hostap: create custom package build
- T4413 (default): Add an API endpoint with basic system stats
- T4537 (bug): MACsec not working with cipher gcm-aes-256

### 3.2.414 2022-08-15

- T4609 (bug): Unable to Restart Container VyOS 1.4
- T4565 (bug): vlan aware bridge not working with - Kernel: T3318: update Linux Kernel to v5.4.205 #249
- T3988 (default): Feature Request: IPsec Multiple local/remote prefix for the tunnel
- T2763 (feature): New SNMP resource request - SNMP over TCP

### 3.2.415 2022-08-14

- T4579 (bug): bridge: can not delete member interface CLI option when VLAN is enabled
- T4421 (default): Add support for floating point numbers in the numeric validator
- T3507 (bug): Bond with mode LACP show u/u in show interfaces even if peer is not configured

### 3.2.416 2022-08-12

- T4603 (feature): Need a config option to specify NAS-IP-Address for vpn l2tp

### 3.2.417 2022-08-10

- T4408 (feature): Add sshguard to protect against brut-forces

### 3.2.418 2022-08-08

- T4586 (feature): Add to NAT66: SNAT destination address and DNAT source address.

### 3.2.419 2022-08-04

- T4257 (feature): Discussion on changing BGP autonomous system number syntax

### 3.2.420 2022-08-02

- T4585 (feature): Rewrite op-mode containers to vyos.opmode
- T4515 (default): Reduce telegraf binary size

### 3.2.421 2022-08-01

- T4581 (bug): 'show system cpu' not working
- T4578 (feature): Rewrite show dns forwarding statistics to new format

### 3.2.422 2022-07-31

- T4580 (bug): Handle the case of op-mode file names with hyphens in GraphQL schema/resolver generation

### 3.2.423 2022-07-30

- T4575 (feature): vyos.utill add new wrapper "rc\_cmd" to get the return code and output
- T4562 (feature): Rewrite show vrf to new format
- T4545 (feature): Rewrite show nat source rules
- T4543 (bug): Show source nat statistics shows incorrect interface
- T4503 (default): Prevent op mode scripts from restarting services if there's a commit in progress
- T4411 (feature): Add migration for service monitoring telegraf influxdb

### 3.2.424 2022-07-29

- T4554 (enhancement): Implement GraphQL resolvers for standardized op-mode scripts
- T4518 (feature): Add XML for CLI conf mode load-balancing wan
- T4544 (enhancement): Generate schema definitions from standardized op-mode scripts

### 3.2.425 2022-07-28

- T4531 (bug): NAT op-mode errors with exclude rules
- T3435 (bug): NAT rules show corruption

### 3.2.426 2022-07-27

- T4571 (bug): Sflow with vrf configured does not use vrf to validate agent-address IP from vrf-configured interfaces
- T4552 (bug): Unable to reset IPsec IPv6 peer

### 3.2.427 2022-07-26

- T4568 (bug): show vpn debug peer doesn't work
- T4556 (feature): fastnetmon: Allow configure white\_list\_path and populate with hosts/networks that should be ignored.
- T4495 (feature): Combine BGP reset op commands

### 3.2.428 2022-07-25

- T4567 (default): Merge experimental branch of GraphQL development
- T4560 (bug): VRF and BGP neighbor local-as error
- T4493 (bug): Incorrect help for "show bgp neighbors"
- T1233 (bug): ipsec vpn sa showing down

### 3.2.429 2022-07-22

- T4145 (bug): Conntrack table not showing after firewall rewriting

### 3.2.430 2022-07-21

- T4555 (feature): fastnetmon: add IPv6 support
- T4553 (default): Allow to set ban time on ddos-protection configuration

### 3.2.431 2022-07-20

- T4056 (bug): Traffic policy not set in live configuration

### 3.2.432 2022-07-18

- T4523 (feature): OP-mode Extend conntrack output to get marks, zones and directions
- T4228 (bug): bond: OS error thrown when two bonds use the same member
- T4539 (feature): qat: update Intel QuickAssist release version 1.7.L.4.16.0-00017
- T4534 (bug): bond: bridge: error out if member interface is assigned to a VRF instance
- T4525 (bug): Delete interface from VRF and add it to bonding error
- T4522 (feature): bond: add ability to specify mii monitor interval via CLI

- T4535 (feature): FRR: upgrade to stable/8.3 version
- T4521 (bug): bond: ARP monitor interval is not configured despite set via CLI
- T4540 (feature): firmware: update to Linux release 20220708

### 3.2.433 2022-07-17

- T4028 (bug): FRR 8.1 routes not being applied to routing table after reboot if an interface has 2 ip addresses

### 3.2.434 2022-07-15

- T4494 (bug): Cannot reset BGP peer within VRF
- T4536 (feature): FRR: move to systemd for daemon control

### 3.2.435 2022-07-14

- T4491 (bug): Use empty string for internal name of root node of config\_tree

### 3.2.436 2022-07-13

- T1375 (feature): Add clear dhcp server lease function

### 3.2.437 2022-07-12

- T4527 (bug): Prevent to create VRF name default
- T4084 (default): Dehardcode the default login banner
- T3948 (feature): IPSec VPN: Add a new option "none" for the connection-type
- T235 (feature): Ability to configure manual IP Rules

### 3.2.438 2022-07-10

- T3836 (bug): Setting a default IPv6 route while getting IPv4 gateway via DHCP removes the IPv4 gateway

### 3.2.439 2022-07-09

- T4507 (feature): IPoE-server add multiplier option for shaper
- T4499 (bug): NAT source translation not showing a single output
- T4468 (bug): web-proxy source group cannot start with a number bug
- T4373 (feature): PPPoE-server add multiplier option for shaper
- T3353 (bug): PPPoE server wrong vlan-range generating config
- T3648 (bug): op-mode: nat rules broken

- T4517 (feature): ip: Add options to enable directed broadcast forwarding

### 3.2.440 2022-07-07

- T4456 (bug): NTP client in VRF tries to bind to interfaces outside VRF, logs many messages
- T4509 (feature): Feature Request: DNS64

### 3.2.441 2022-07-06

- T4513 (bug): Webproxy monitor commands do not work
- T4299 (feature): Firewall - GeoIP filtering

### 3.2.442 2022-07-05

- T4378 (bug): Unable to submit wildcard ("\*.example.com") A or AAAA records in dns forwarder
- T2683 (default): no dual stack in system static-host-mapping host-name
- T478 (feature): Firewall address group (multi and nesting)

### 3.2.443 2022-07-04

- T4501 (bug): Syslog-identifier does not work in event handler
- T3600 (bug): DHCP Interface static route breaks PBR
- T4498 (feature): bridge: Add option to enable/disable IGMP/MLD snooping

### 3.2.444 2022-07-01

- T2455 (bug): No support for the IPv6 VTI
- T4490 (feature): BGP- warning message that AFI/SAFI is needed to establish the neighborhood
- T4489 (bug): MPLS sysctl not persistent for tunnel interfaces

### 3.2.445 2022-06-29

- T4477 (feature): router-advert: support RDNSS lifetime option

### 3.2.446 2022-06-28

- T4486 (bug): Container can't be deleted
- T4473 (bug): Use container network without network declaration error
- T4458 (feature): Firewall - add support for matching ip ttl in firewall rules
- T3907 (feature): Firewall - Set log levels

### 3.2.447 2022-06-27

- T4484 (default): Firewall op-mode summary doesn't correctly handle address group containing ranges

### 3.2.448 2022-06-25

- T4482 (bug): dhcp: toggle of "dhcp-options no-default-route" has no effect
- T4483 (feature): Upgrade fastnetmon to v1.2.2 community edition

### 3.2.449 2022-06-22

- T1748 (feature): vbash: beautify tab completion output/line breaks

### 3.2.450 2022-06-20

- T1856 (feature): Support configuring IPSec SA bytes

### 3.2.451 2022-06-18

- T4467 (bug): Validator Does Not Accept Signed Numbers

### 3.2.452 2022-06-17

- T4209 (bug): Firewall incorrect handler for recent count and time

### 3.2.453 2022-06-16

- T4352 (bug): wan-load balance - priority traffic rule doesn't work

### 3.2.454 2022-06-15

- T4450 (feature): Route-map - Extend options for ip|ipv6 address match
- T4449 (feature): Route-map - Extend options for ip next-hop match
- T990 (feature): Make DNAT/SNAT a valid state in firewall rules.

### 3.2.455 2022-06-12

- T4420 (feature): Feature Request: ocserv: show configured 2FA OTP key
- T4380 (default): Feature Request: ocserv: 2FA OTP key generator in VyOS CLI

### 3.2.456 2022-06-10

- T4365 (bug): NAT - Error on setting up tables
- T4465 (feature): node.def generation misses whitespace on multiple use of <path>

### 3.2.457 2022-06-09

- T4444 (default): sstp: Feature request. Port number changing support
- T2580 (feature): Support for ip pools for ippoe

### 3.2.458 2022-06-08

- T4447 (bug): DHCPv6 prefix delegation `sla-id` limited to 128

### 3.2.459 2022-05-31

- T4212 (default): PermissionError when generating/installing server Certificate (generate pki certificate sign ...)
- T4199 (bug): Commit failed when setting icmpv6 type any
- T4148 (bug): Firewall - Error messages not that clear as it were in old firewall
- T3659 (bug): Configuration won't accept IPv6 addresses for site-to-site VPN tunnel prefixes/traffic selectors

### 3.2.460 2022-05-30

- T4315 (feature): Telegraf - Output to prometheus

### 3.2.461 2022-05-29

- T2473 (feature): Xml for EIGRP [conf\_mode]

### 3.2.462 2022-05-28

- T4448 (feature): rip: add support for explicit version selection

### 3.2.463 2022-05-26

- T4442 (feature): HTTP API add action "reset"

### 3.2.464 2022-05-25

- T4410 (feature): Telegraf - Output to Splunk
- T4382 (bug): Replacing legacy loadFile exposes missing steps in migration scripts and other errors

### 3.2.465 2022-05-21

- T4437 (bug): flow-accounting: support IPv6 flow collectors

### 3.2.466 2022-05-20

- T4418 (feature): Telegraf - output Plugin azure-data-explorer

### 3.2.467 2022-05-19

- T4434 (bug): DMVPN: cisco-authentication password length is 8 characters
- T3938 (default): Rewrite the uptime script in Python to allow using it as a library
- T4334 (default): Make the config lexer reentrant

### 3.2.468 2022-05-17

- T4424 (bug): policy local-route6 shows ipv4 format

### 3.2.469 2022-05-16

- T4377 (default): generate tech-support archive includes previous archives

### 3.2.470 2022-05-12

- T4417 (bug): VRRP doesn't start with conntrack-sync
- T4100 (feature): Firewall increase maximum number of rules

### 3.2.471 2022-05-11

- T4405 (bug): DHCP client sometimes ignores `no-default-route` option of an interface

### 3.2.472 2022-05-10

- T4156 (default): Adding DHCP Option 13 (bootfile-size)
- T1972 (feature): Allow setting interface name for virtual\_ipaddress in VRRP VRID

### 3.2.473 2022-05-07

- T4361 (bug): `vyos.config.exists()` does not work for nodes with multiple values
- T4354 (bug): Slave interfaces fall out from bonding during configuration change
- T4419 (feature): vrf: support to disable IP forwarding within a given VRF

### 3.2.474 2022-05-06

- T4385 (bug): bgp: peer-group member cannot override remote-as of peer-group

### 3.2.475 2022-05-05

- T4414 (feature): Add route-map "as-path prepend last-as x" option

### 3.2.476 2022-05-03

- T4395 (feature): Extend show vpn debug

### 3.2.477 2022-05-01

- T4369 (bug): OpenVPN: daemon not restarted on changes to "openvpn-option" CLI node
- T4363 (bug): salt-minion: default mine\_interval option is not set
- T4353 (feature): Add Jinja2 linter to vyos-1x build process

### 3.2.478 2022-04-29

- T4388 (bug): dhcp-server: missing constraint on tftp-server-name option
- T4366 (bug): geneve: interface is removed on changes to e.g. description

### 3.2.479 2022-04-28

- T4400 (bug): Container OP mode has delete where show and update should be

### 3.2.480 2022-04-27

- T4398 (bug): IPSec site-to-site generates unexpected passthrough option
- T4397 (feature): arp: migrate static ARP entry configuration to get\_config\_dict() and make it VRF aware
- T4357 (feature): Allow free-form setting of DHCPv6 server options

### 3.2.481 2022-04-26

- T4210 (bug): NAT source/destination negated ports throws an error
- T4235 (default): Add config tree diff algorithm

### 3.2.482 2022-04-25

- T4390 (feature): op-mode: extend "show log" and "monitor log" with additional daemons/subsystems to read journalctl logs
- T4391 (bug): PPPoE: IPv6 not working after system boot

### 3.2.483 2022-04-24

- T4342 (bug): "show ip ospf neighbor address x.x.x.x" gives "unknown command" error

### 3.2.484 2022-04-23

- T4386 (default): Applying limiter on traffic-policy "in" fails, incorrectly reports mirror or redirect policy in use

### 3.2.485 2022-04-22

- T4389 (feature): dhcp: add vendor option support for Ubiquiti Unifi controller

### 3.2.486 2022-04-21

- T4384 (feature): pppoe: replace default-route CLI option with common CLI nodes already present for DHCP

### 3.2.487 2022-04-20

- T4345 (bug): New firewall code does not accept "rate/time interval" syntax used in old config
- T4231 (feature): Feature Request: ocserv: 2FA (password+OTP) support in Openconnect

### 3.2.488 2022-04-19

- T4379 (bug): PPPoE: default-route lost after applying additional static routes
- T4344 (bug): DHCP statistics not matching, conf-mode generates incorrect pool name with dash
- T4268 (bug): Elevated LA while using VyOS monitoring feature

### 3.2.489 2022-04-18

- T4351 (bug): Openvpn conf-mode "openvpn-option" is not respected
- T4278 (default): vyos-vm-images: fix vagrant libvirt box
- T4368 (bug): bgp: AS specified for local as is the same as the remote as and this is not allowed.
- T4370 (feature): vxlan: geneve: support configuration of df bit option

### 3.2.490 2022-04-15

- T4327 (default): Ethernet interface configuration fails on Hyper-V due to speed/duplex/autoneg ethtool command error
- T4364 (feature): salt-minion: Upgrade to 3004 and migrate to get\_config\_dict()

### 3.2.491 2022-04-13

- T4333 (feature): Jinja2: add plugin to test if a variable is defined and not none to reduce template complexity

### 3.2.492 2022-04-08

- T4331 (bug): IPv6 link local addresses are not configured when an interface is in a VRF
- T4347 (default): Return complete and consistent error codes from HTTP API
- T4339 (bug): wwan: tab-completion results in "No such file or directory" if there is no WWAN interface
- T4338 (bug): wwan: changing interface description should not trigger reconnect
- T4324 (bug): wwan: check alive script should only be run via cron if a wwan interface is configured at all

### 3.2.493 2022-04-07

- T4330 (bug): MTU settings cannot be applied when IPv6 is disabled
- T4346 (feature): Deprecate "system ipv6 disable" option to disable address family within OS kernel
- T4319 (bug): The command "set system ipv6 disable" doesn't work as expected.
- T4341 (feature): login: disable user-account prior to deletion and wait until deletion is complete
- T4336 (feature): isis: add support for MD5 authentication password on a circuit

### 3.2.494 2022-04-06

- T4308 (feature): Op-comm "Show log frr" to view specific protocol logs

### 3.2.495 2022-04-04

- T4329 (bug): Bgp policy route-map bug with set several extcommunity rt

### 3.2.496 2022-04-02

- T4335 (bug): open-vmdk fails to build under gcc-10.+

### 3.2.497 2022-04-01

- T4332 (bug): bgp: deterministic-med cannot be disabled while addpath-tx-bestpath-per-AS is in use

### 3.2.498 2022-03-31

- T4326 (feature): Add bgp option no-suppress-duplicates
- T4323 (default): ospf6d crashes on latest vyos nightly

### 3.2.499 2022-03-29

- T3686 (bug): Bridging OpenVPN tap with no local-address breaks
- T3635 (default): Add ability to use mDNS repeater with VRRP

### 3.2.500 2022-03-26

- T4321 (default): Allow BGP neighbors between different VIFs on the same VyOS

### 3.2.501 2022-03-24

- T4301 (bug): The "arp-monitor" option in bonding interface settings does not work
- T4294 (bug): Adding a new openvpn-option does not restart the OpenVPN process
- T4290 (bug): BGP source-interface fails to commit
- T4230 (bug): OpenVPN server configuration deleted after reboot when using a VRRP virtual-address

### 3.2.502 2022-03-23

- T4314 (bug): Latest 1.4 Rolling release config migration error

### 3.2.503 2022-03-21

- T4304 (feature): [OSPF]import/export filter inter-area prefix

### 3.2.504 2022-03-20

- T4298 (default): vyos-vm-images: fix ansible group name and remove obsolete empty command

### 3.2.505 2022-03-18

- T4286 (bug): Fix for firewall ipv6 name address validator

### 3.2.506 2022-03-15

- T4302 (feature): FRRouting upgrade to release 8.2.2
- T4293 (default): Add "set ip-next-hop unchanged" in route-map

### 3.2.507 2022-03-14

- T4275 (default): Incorrect val\_help for local/remote prefix in ipsec vpn

### 3.2.508 2022-03-12

- T4296 (bug): Interface config injected by Cloud-Init may interfere with VyOS native
- T4265 (feature): Add op-mode for bgp flowspec state and routes

### 3.2.509 2022-03-11

- T4297 (bug): Interface configuration saving fails for ice/iavf based interfaces because they can't change speed/duplex settings

### 3.2.510 2022-03-09

- T3981 (feature): VRF support for flow-accounting

### 3.2.511 2022-03-05

- T4259 (bug): The conntrackd daemon can be started wrongly

### 3.2.512 2022-03-03

- T4283 (feature): Add support to "reject" routes - emit an ICMP unreachable when matched

### 3.2.513 2022-03-01

- T4277 (feature): flow-accounting: support sending flow-data via VRF interface

### 3.2.514 2022-02-28

- T4273 (bug): ssh: Upgrade from 1.2.X to 1.3.0 breaks config
- T4115 (bug): reboot in <x> not working as expected
- T3656 (bug): IPSec 1.4 : "show vpn ike sa" does not show the correct default ike version

### 3.2.515 2022-02-26

- T4272 (feature): lldp: migrate Python script to use get\_config\_dict()

### 3.2.516 2022-02-24

- T4267 (bug): Error - Missing required "ip key" parameter

### 3.2.517 2022-02-23

- T4194 (bug): prefix-list no check for duplicate entries
- T4264 (bug): vxlan: interface is destroyed and rebuild on description change
- T4263 (bug): vyos.util.leaf\_node\_changed() dos not honor valueLess nodes

### 3.2.518 2022-02-21

- T4120 (feature): [VXLAN] add ability to set multiple unicast-remotes

### 3.2.519 2022-02-20

- T4254 (feature): VPN IPSec charon add options cisco\_flexvpn and install\_virtual\_ip\_on
- T4249 (feature): Add support for device mapping in containers
- T3617 (bug): IPSec 1.4 generate invalid configuration
- T4261 (feature): MACsec: add DHCP client support
- T4203 (bug): Reconfigure DHCP client interface causes brief outages

### 3.2.520 2022-02-19

- T4258 (bug): [DHCP-SERVER] error parameter on Failover

### 3.2.521 2022-02-17

- T4255 (bug): Unexpected print of dict bridge on delete
- T4240 (bug): Cannot add wlan0 to bridge via configure
- T4154 (bug): Error add second gre tunnel with the same source interface

### 3.2.522 2022-02-16

- T4237 (bug): Conntrack-sync error - error adding listen-address command

### 3.2.523 2022-02-15

- T4160 (bug): Firewall - Error in rules that matches everything except something
- T3006 (bug): Accel-PPP & vlan-mon config get invalid VLAN
- T3494 (bug): DHCPv6 leases traceback when PD using
- T1292 (bug): Issues while deleting all rules from a firewall

### 3.2.524 2022-02-13

- T4242 (bug): ethernet speed/duplex can never be switched back to auto/auto
- T4191 (bug): Lost access to host after VRF re-creating

### 3.2.525 2022-02-11

- T3872 (feature): Add configurable telegraf monitoring service

### 3.2.526 2022-02-08

- T4227 (bug): Typo in help completion of hello-time option of bridge interface

### 3.2.527 2022-02-07

- T4233 (bug): ssh: sync regex for allow/deny usernames to "system login"

### 3.2.528 2022-02-06

- T4223 (bug): policy route cannot have several entries with the same table
- T4216 (bug): Firewall: can't use negated groups in firewall rules
- T4178 (bug): policy based routing tcp flags issue
- T4164 (bug): PBR: network groups (as well as address and port groups) don't resolve in `nftables\_policy.conf`
- T3970 (feature): Add support for op-mode PKI direct install into an active config session

- T3828 (bug): ipsec: Subtle change in "pfs enable" behavior from equuleus -> sagitta

### 3.2.529 2022-02-05

- T4226 (bug): VRRP transition-script does not work for groups name which contains -(minus) sign

### 3.2.530 2022-02-04

- T4196 (bug): DHCP server client-prefix-length parameter results in non-functional leases

### 3.2.531 2022-02-03

- T4218 (bug): firewall: rule name is not allowed to start with a number
- T3643 (bug): show vpn ipsec sa doesn't show tunnels in "down" state

### 3.2.532 2022-02-01

- T4224 (bug): Ethernet interfaces configured for DHCP not working on latest rolling snapshot (vyos-1.4-rolling-202201291849-amd64.iso)
- T4225 (bug): Performance degradation with latest rolling release
- T4220 (bug): Commit broke dhclient 78b247b724f74bdabab0706aaa7f5b00e5809bc1
- T4138 (bug): NAT configuration allows to set incorrect port range and invalid port

### 3.2.533 2022-01-28

- T4184 (bug): NTP allow-clients address doesn't work it allows to use ntp server for all addresses
- T4217 (bug): firewall: port-group requires protocol to be set - but not in VyOS 1.3

### 3.2.534 2022-01-27

- T4213 (default): ipv6 policy routing not working anymore
- T4188 (bug): Firewall does not correctly handle conntracking
- T3762 (feature): Support network and address groups for policy ipv6-route
- T3560 (feature): Ability to create groups of MAC addresses
- T3495 (feature): Modernising port/protocol definitions

### 3.2.535 2022-01-25

- T4205 (feature): Disable Debian Version in SSH (DebianBanner->no)
- T4131 (bug): Show firewall group incorrect format members

### 3.2.536 2022-01-24

- T4204 (feature): Update Accel-PPP to a newer revision
- T1795 (default): Commit rollback by timeout

### 3.2.537 2022-01-23

- T4186 (bug): Firewall icmp type - Offered options not supported
- T4181 (bug): Firewall ipv6-network-group - incorrect description on helper

### 3.2.538 2022-01-21

- T4200 (bug): Assigning ipv6-name to interface is not generating nftables rules
- T4144 (bug): Firewall address-group - Improve error messages
- T4137 (bug): Firewall group configuration allows to set incorrect port range and invalid port
- T4133 (bug): Firewall network group error with zone-based firewall rules

### 3.2.539 2022-01-20

- T4171 (bug): Interface config migration error on 1.2.8 -> 1.4 upgrade

### 3.2.540 2022-01-19

- T4195 (feature): [OSPF-ECMP]enable set maximun-path

### 3.2.541 2022-01-18

- T4159 (bug): Empty firewall group (address, network & port) generates invalid nftables config, commit fails
- T4155 (bug): PBR: `set table main` fails in `firewall.py` with newer rolling releases
- T3873 (feature): Zone based Firewall - Filter traffic in same zone
- T3286 (feature): Switch the firewall from iptables to nftables
- T292 (feature): [ZBF] Allow filtering intra zone traffic

### 3.2.542 2022-01-17

- T3164 (bug): console-server ssh does not work with RADIUS PAM auth

### 3.2.543 2022-01-15

- T4183 (feature): IPv6 link-local address not accepted as wireguard peer
- T4150 (bug): VRRP with conntrack-sync does not work
- T4110 (feature): [IPV6-SSH/DNS} enable IPv6 link local addresses as listen-address %eth0

### 3.2.544 2022-01-14

- T4182 (bug): Show vrrp if vrrp not configured bug
- T4179 (feature): Add op-mode CLI for show high-availability virtual-server

### 3.2.545 2022-01-13

- T4175 (bug): BGP configuration failed
- T4109 (feature): Extend high-availability/keepalived for support virtual-server lb

### 3.2.546 2022-01-12

- T4174 (bug): Validation fails when entering port range with upper port 65535
- T4162 (bug): VPN ipsec ike-group - Incorrect value help for ikev2-reauth
- T4161 (bug): Policy route-map - Incorrect value help for local preference
- T4152 (bug): NHRP shortcut-target holding-time does not work

### 3.2.547 2022-01-11

- T4149 (bug): [Firewall-IPV6] Error delete Fw rules on VIF/INT
- T3950 (bug): CLI backtrace on update if DNS not defined
- T4166 (bug): Debug output missing when frr.py called under vyos-configd

### 3.2.548 2022-01-10

- T3299 (bug): Allow the web proxy service to listen on all IP addresses
- T3115 (feature): Add support for firewall on L3 VIF bridge interface

### 3.2.549 2022-01-09

- T4142 (bug): Input ifbX interfaces not displayed in op-mode
- T3914 (bug): VRRP rfc3768-compatibility doesn't work with unicast peers

### 3.2.550 2022-01-08

- T4116 (bug): Webproxy/Squid not working with IPv6 listen-address

### 3.2.551 2022-01-07

- T3924 (bug): VRRP stops working with VRF

### 3.2.552 2022-01-06

- T4135 (bug): Declare zone policy firewall without local zone errors
- T4130 (bug): Firewall state policy errors chain
- T4141 (bug): Set high-availability vrrp sync-group without members error

### 3.2.553 2022-01-04

- T4134 (bug): Incorrect firewall protocol completion help uppercase and duplicates
- T4132 (bug): Impossible to show a specific firewall group

### 3.2.554 2022-01-03

- T4126 (feature): Ability to set priority to site to site IPSec vpn tunnels
- T4052 (bug): Validator return traceback on VRRP configuration with the script path not in config dir
- T4128 (bug): keepalived: Upgrade package to add VRF support

### 3.2.555 2021-12-31

- T4081 (bug): VRRP health-check script stops working when setting up a sync group

### 3.2.556 2021-12-30

- T4124 (feature): snmp: migrate to get\_config\_dict()

### 3.2.557 2021-12-29

- T4111 (bug): IPSec generates wrong configuration colons for IPv6 peers
- T4023 (feature): Add grepcidr or similar functionality
- T4086 (default): system login banner is not removed on deletion.

### 3.2.558 2021-12-28

- T3380 (bug): "show vpn ike sa" does not display IPv6 peers

### 3.2.559 2021-12-27

- T3979 (bug): vyos-hostd unable to hostfile-update
- T2566 (bug): sstp not able to run tunnels ipv6 only
- T4093 (bug): SNMPv3 snmpd.conf generation bug
- T2764 (enhancement): Increase maximum number of NAT rules

### 3.2.560 2021-12-26

- T4104 (bug): RAID1: "add raid md0 member sda1" does not restore boot sector
- T4108 (default): OSPFv3: add support for auto-cost parameter
- T4107 (default): OSPFv3: add support for "default-information originate"

### 3.2.561 2021-12-25

- T4101 (bug): commit-archive: Use of uninitialized value \$source\_address in concatenation
- T4099 (feature): flow-accounting: sync "source-ip" and "source-address" between netflow and sflow ion CLI
- T4097 (feature): flow-accounting: migrate implementation to get\_config\_dict()
- T4105 (feature): flow-accounting: drop "sflow agent-address auto"
- T4106 (feature): flow-accounting: support specification of capture packet lenght
- T4102 (feature): OSPFv3: add support for NSSA area-type
- T4055 (feature): Add VRF support for HTTP(S) API service

### 3.2.562 2021-12-24

- T3854 (bug): Missing op-mode commands for conntrack-sync

### 3.2.563 2021-12-23

- T3354 (default): Convert strip-private script from Perl to Python

### 3.2.564 2021-12-22

- T3678 (bug): VyOS 1.4: Invalid error message while deleting ipsec vpn configuration
- T3356 (feature): Script for remote file transfers

### 3.2.565 2021-12-21

- T4083 (bug): Cluster heartbeat doesn't start b.c lack of directory /run/heartbeat/
- T4070 (bug): NATv4 : inbound-interface type "any" is missing.
- T4053 (bug): VRRP impossible to set scripts out of the /config directory
- T3931 (bug): SSTP doesn't work after rewriting to PKI

### 3.2.566 2021-12-20

- T4088 (default): Fix typo in login banner

### 3.2.567 2021-12-19

- T3912 (default): Use a more informative default post-login banner

### 3.2.568 2021-12-17

- T4059 (bug): VRRP sync-group transition script does not persist after reboot

### 3.2.569 2021-12-16

- T4046 (feature): Sflow - Add Source address parameter
- T3556 (bug): Commit-archive via scp causes 100% CPU on boot
- T4076 (enhancement): Allow setting CORS options in HTTP API
- T4037 (default): HTTP transfers do not follow redirects
- T4029 (default): Broken SFTP uploads

### 3.2.570 2021-12-15

- T4077 (bug): op-mode: bfd: drop "show protocols bfd" in favour of "show bfd"
- T4073 (bug): "show protocols bfd peer <>" shows incorrect peer information.

### 3.2.571 2021-12-14

- T4071 (feature): Allow HTTP API to bind to unix domain socket

### 3.2.572 2021-12-12

- T4069 (feature): BGP: add additional available parameters to VyOS CLI
- T4036 (bug): VXLAN incorrect raiseError if set multicast network instead of single address

### 3.2.573 2021-12-10

- T4068 (feature): Python: ConfigError should insert line breaks into the error message

### 3.2.574 2021-12-09

- T4033 (bug): VRRP - Error security when setting scripts
- T4064 (bug): IP address for vif is not removed from the system when deleted in configuration
- T4060 (enhancement): Extend configquery for use before boot configuration is complete
- T4058 (bug): BFD: add BGP and OSPF "bfd profile" support
- T4054 (bug): BFD profiles configuration incorrect behavior.

### 3.2.575 2021-12-07

- T4041 (servicerequest): "transition-script" doesn't work on "sync-group"

### 3.2.576 2021-12-06

- T4012 (feature): Add VRF support for TFTP

### 3.2.577 2021-12-04

- T4049 (feature): support command-style output with compare command
- T4047 (bug): Wrong regex validation in XML definitions
- T4042 (bug): BGP L2VPN / EVPN and RD type 0 set
- T4048 (bug): BGP: L2VPN/EVPN and individual RD and RT settings for each VNI
- T4045 (bug): Unable to "format disk <new> like <old>"
- T4044 (feature): BFD: add vrf support
- T4043 (feature): BFD: add support for passive mode

### 3.2.578 2021-12-02

- T4035 (bug): Geneve interfaces aren't displayed by operational mode commands

### 3.2.579 2021-12-01

- T3695 (bug): OpenConnect reports commit success when ocscriv fails to start due to SSL cert/key file issues

### 3.2.580 2021-11-30

- T4010 (bug): DMVPN generates incorrect configuration life\_time for swanctl.conf
- T3725 (feature): show configuration in json format

### 3.2.581 2021-11-29

- T3946 (enhancement): Automatically resize the root partition if the drive has extra space

### 3.2.582 2021-11-28

- T3999 (bug): show lldp neighbor Traceback error
- T3928 (feature): Add OSPFv3 VRF support

### 3.2.583 2021-11-27

- T3755 (feature): ospf: adjust to new FRR 8 syntax where "no passive-interface " moved to interface section
- T3753 (feature): frr: upgrade to stable/8.1 release train

### 3.2.584 2021-11-26

- T3978 (bug): containers add network without declaring prefix raise ConfigError

### 3.2.585 2021-11-25

- T4006 (default): Add additional Linux capabilities to container configuration
- T3986 (bug): Incorrect description for vpn ipsec site-to-site authentication and connection

### 3.2.586 2021-11-24

- T4015 (feature): Update Accel-PPP to a newer revision
- T3865 (bug): loadkey command help text missing escape sequence
- T1083 (feature): Implement persistent/random address and port mapping options for NAT rules

### 3.2.587 2021-11-23

- T3990 (bug): WATCHFRR: crashlog and per-thread log buffering unavailable (due to files left behind in /var/tmp/frr/ after reboot)

### 3.2.588 2021-11-20

- T3998 (bug): route-target completion incorrect description

### 3.2.589 2021-11-19

- T4003 (bug): API for "show interfaces ethernet" does not include the interface description
- T4011 (bug): ethernet: deleting interface should place interface in admin down state

### 3.2.590 2021-11-18

- T3612 (bug): IPoE Server address pool issues.
- T3995 (feature): OpenVPN: do not stop/start service on configuration change
- T4008 (feature): dhcp: change client retry interval from 300 -> 60 seconds
- T3795 (bug): WWAN: issues with non connected interface / no signal
- T3510 (bug): RADIUS username is not shown on CLI

### 3.2.591 2021-11-17

- T3350 (bug): OpenVPN config file generation broken
- T3996 (bug): SNMP service error in log

### 3.2.592 2021-11-15

- T3994 (bug): VRF: unable to delete vrf when name contains numbers, hyphen or underscore
- T3960 (bug): FRR Misconfig when using multiple VRF VNI
- T3724 (feature): Allow setting host-name in l2tp section of accel-ppp
- T645 (feature): Allow multiple prefixes in ipsec tunnel

### 3.2.593 2021-11-10

- T3966 (default): OpenVPN fix the smoketests
- T3834 (default): [OPENVPN] Support for Two Factor Authentication totp.
- T3982 (bug): DHCP server commit fails if static-mapping contains + or .

### 3.2.594 2021-11-09

- T3962 (bug): Image cannot be built without open-vm-tools

### 3.2.595 2021-11-07

- T3626 (bug): Configuring and disabling DHCP Server

### 3.2.596 2021-11-06

- T3514 (bug): NIC flap at any interface change

### 3.2.597 2021-11-05

- T3972 (bug): Removing vif-c interface raises KeyError

### 3.2.598 2021-11-04

- T3969 (bug): Container incorrect raiseError format if network doesn't exist
- T3662 (bug): Container configuration upgrade destroys system
- T3964 (bug): SSTP: local-user static-ip CLI node accepts invalid IPv4 addresses

### 3.2.599 2021-11-03

- T3952 (default): Add sh bgp ipv4/ipv6 vpn command
- T3610 (bug): DHCP-Server creation for not primary IP address fails

### 3.2.600 2021-11-01

- T3958 (default): OpenVPN breaks the smoketests
- T3956 (bug): GRE tunnel - unable to move from source-interface to source-address, commit error

### 3.2.601 2021-10-31

- T3945 (feature): Add route-map for bgp aggregate-address
- T3954 (bug): FTDI cable makes VyOS sagitta latest hang, /dev/serial unpopulated, config system error
- T3943 (bug): "netflow source-ip" prevents image upgrades if IP address does not exist locally

### 3.2.602 2021-10-29

- T3942 (feature): Generate IPSec debug archive from op-mode

### 3.2.603 2021-10-28

- T3951 (bug): After resetting vti ipsec tunnel old child SA still active
- T3941 (bug): "show vpn ipsec sa" shows established time of parent SA not child SA's
- T3916 (feature): Add additional Linux capabilities to container configuration

### 3.2.604 2021-10-27

- T3944 (bug): VRRP fails over when adding new group to master

### 3.2.605 2021-10-22

- T3897 (feature): Dynamic DNS doesn't work with IPv6 addresses
- T3832 (feature): Allow to set DHCP client-id in hexadecimal format
- T3188 (bug): Tunnel local-ip to dhcp-interface Change Fails to Update
- T3917 (default): Use Avahi as mDNS repeater for IPv6 support

### 3.2.606 2021-10-21

- T3926 (bug): strip-private does not sanitize "cisco-authentication" from NHRP configuration
- T3925 (feature): Tunnel: dhcp-interface not implemented - use source-interface instead
- T3923 (feature): Kernel: Enable TLS/IPSec offload support for Mellanox ConnectX NICs
- T3927 (feature): Kernel: Enable kernel support for HW offload of the TLS protocol

### 3.2.607 2021-10-20

- T3918 (bug): DHCPv6 prefix delegation incorrect verify error
- T3921 (bug): tunnel: KeyError when using dhcp-interface

### 3.2.608 2021-10-19

- T3396 (bug): syslog can't be configured with an ipv6 literal destination in 1.2.x

### 3.2.609 2021-10-18

- T3002 (default): VRRP change on IPSec interface causes packet routing issues

### 3.2.610 2021-10-17

- T3786 (bug): GRE tunnel source address 0.0.0.0 error
- T3217 (default): Save FRR configuration on each commit
- T3381 (bug): Change GRE tunnel failed
- T3254 (bug): Dynamic DNS status shows incorrect last update time
- T1243 (bug): BGP local-as accept wrong values
- T697 (bug): Clean up and sanitize package dependencies
- T578 (feature): Support Linux Container

### 3.2.611 2021-10-16

- T3879 (bug): GPG key verification fails when upgrading from a 1.3 beta version

### 3.2.612 2021-10-15

- T3748 (bug): Container deletion bug
- T3693 (feature): ISIS Route redistribution ipv6 support missing
- T3676 (feature): Container option to add Linux capabilities
- T3613 (feature): Selectors for route-based IPsec tunnel (vti)
- T3692 (bug): VyOS build failing due to repo.saltstack.com
- T3673 (feature): BGP large-community del operation missing

### 3.2.613 2021-10-14

- T3811 (bug): NAT (op\_mode): NAT op\_mode command fails.
- T3801 (feature): containers: do not use podman CLI to create container networks

### 3.2.614 2021-10-13

- T3904 (bug): NTP pool associations silently fail
- T3277 (feature): DNS Forwarding - reverse zones

### 3.2.615 2021-10-12

- T3216 (bug): Removal of restricted-shell broke configure mode for RADIUS users
- T3881 (bug): Wrong description for container section restart
- T3868 (bug): Regex and/or wildcard not accepted with large-community-list
- T3701 (bug): ipoe server fails to start when configuring radius dynamic-author on ipoe

### 3.2.616 2021-10-10

- T3750 (bug): pdns-recursor 4.4 issue with dont-query and private DNS servers
- T3885 (default): dhcpv6-pd: randomly generated DUID is not persisted
- T3899 (enhancement): Add support for hd44780 LCD displays

### 3.2.617 2021-10-09

- T3894 (bug): Tunnel Commit Failed if system does not have `eth0`

### 3.2.618 2021-10-08

- T3893 (bug): MGRE Tunnel commit crash If sit tunnel available

### 3.2.619 2021-10-05

- T3741 (feature): [BGP] default no-ipv4-unicast - by default

### 3.2.620 2021-10-04

- T3888 (bug): Incorrect warning when poweroff command executed from configure mode.
- T3890 (feature): dhcp(v6): provide op-mode commands to retrieve both server and client logfiles
- T3889 (feature): Migrate to journalctl when reading daemon logs

### 3.2.621 2021-10-03

- T3880 (bug): EFI boot shows error on display

### 3.2.622 2021-10-02

- T3882 (feature): Upgrade PowerDNs recursor to 4.5 series
- T3883 (bug): VRF - Delete vrf config on interface

### 3.2.623 2021-09-30

- T3874 (bug): D-Link Ethernet Interface not working.
- T3869 (default): Rewrite vyatta\_net\_name/vyatta\_interface\_rescan in Python

### 3.2.624 2021-09-28

- T3853 (default): nat66 rules gets deleted on reboot in 1.4-rolling-202109240217

### 3.2.625 2021-09-27

- T3863 (default): nat66: commit fails/hangs on non existing interface

### 3.2.626 2021-09-26

- T3860 (bug): Error on pppoe, tunnel and wireguard interfaces for IPv6 EUI64 addresses
- T3857 (feature): reboot: send wall message to all users for information
- T3867 (bug): vxlan: multicast group address is not validated
- T3859 (bug): Add "log-adjacency-changes" to ospfv3 process
- T3826 (bug): PKI: op-mode - do input validation when listing certificates

### 3.2.627 2021-09-25

- T3657 (default): BGP neighbors ipv6 not able to establish with IPv6 link-local addresses

### 3.2.628 2021-09-23

- T3850 (bug): Dots are no longer allowed in SSH public key names

### 3.2.629 2021-09-21

- T3847 (feature): keepalived/vrrp: migrate to get\_config\_dict() - cleanup

### 3.2.630 2021-09-20

- T3823 (bug): strip-private does not filter public IPv6 addresses

### 3.2.631 2021-09-19

- T3841 (feature): dhcp-server: add ping-check option to CLI
- T2738 (bug): Modifying configuration in the "interfaces" section from VRRP transition scripts causes configuration lockup and high CPU utilization
- T3840 (feature): dns forwarding: Cache size should allow values > 10k
- T3672 (bug): DHCP-F0 with multiple subnets results in invalid/non-functioning dhcpd.conf configuration file output

### 3.2.632 2021-09-18

- T3831 (bug): External traffic stops routing when IPSEC tunnel comes up with interface vti0
- T1968 (default): Allow multiple static routes in dhcp-server
- T3838 (feature): dhcp-server - sync cli for name-servers to other subsystems
- T3839 (feature): dhcp-server: Allow configuration of a DNS server and domain name on the shared-network level

### 3.2.633 2021-09-17

- T3830 (bug): ipsec: remote-id no longer included in IKE AUTH if not explicitly specified

### 3.2.634 2021-09-11

- T3402 (feature): Add VyOS programming library for operational level commands

### 3.2.635 2021-09-10

- T3802 (bug): Commit fails if ethernet interface doesn't support flow control
- T3819 (bug): Upgrade Salt Stack 3002.3 -> 3003 release train
- T915 (feature): MPLS Support

### 3.2.636 2021-09-09

- T3812 (bug): Vyos and frr route-map config out of sync
- T3814 (bug): wireguard: commit error showing incorrect peer name from the configured name
- T3805 (bug): OpenVPN insufficient privileges for rtnetlink when closing TUN/TAP interface
- T3815 (bug): pki : the file command 'generate pki wireguard key-pair file' is not working

### 3.2.637 2021-09-07

- T1894 (bug): FRR config not loaded after daemons segfault or restart
- T3807 (bug): Op Command "show interfaces wireguard" does not show the output

### 3.2.638 2021-09-06

- T3806 (bug): Don't set link local ipv6 address if MTU less then 1280
- T3803 (default): Add source-address option to the ping CLI
- T3431 (bug): Show version all bug
- T2920 (bug): Commit crash when adding the second mGRE tunnel with the same key

### 3.2.639 2021-09-05

- T3804 (feature): cli: Migrate and merge "system name-servers-dhcp" into "system name-server"

### 3.2.640 2021-09-04

- T3619 (bug): Performance Degradation 1.2 --> 1.3 | High ksoftirqd CPU usage

### 3.2.641 2021-09-03

- T3788 (bug): Keys are not allowed with ipip and sit tunnels
- T3634 (feature): Add op command option for ping for do not fragment bit to be set
- T3798 (feature): bgp: add support for "neighbor <X> local-as replace-as" option

### 3.2.642 2021-09-02

- T3792 (bug): login: A hyphen present in a username from "system login user" is replaced by an underscore
- T3790 (bug): Does not possible to configure PPTP static ip-address to users
- T2947 (bug): Nat translation many-many with prefix does not map 1-1.

### 3.2.643 2021-08-31

- T3789 (feature): Add custom validator for base64 encoded CLI data
- T3782 (default): Ingress Shaping with IFB No Longer Functional with 1.3

### 3.2.644 2021-08-30

- T3768 (default): Remove early syntaxVersion implementation
- T2941 (default): Using a non-ASCII character in the description field causes UnicodeDecodeError in configsource.py
- T3787 (bug): Remove deprecated UDP fragmentation offloading option

### 3.2.645 2021-08-29

- T3708 (bug): isisd and gre-bridge commit error
- T3783 (bug): "set protocols isis spf-delay-ietf" is not working
- T2750 (default): Use m4 as a template processor

### 3.2.646 2021-08-28

- T3743 (bug): l2tp doesn't work after reboot if outside-address not 0.0.0.0

### 3.2.647 2021-08-27

- T3182 (bug): Main blocker Task for FRR 7.4/7.5 series update
- T3568 (feature): Add XML for firewall conf-mode
- T2108 (default): Use minisign/signify instead of GPG for release signing

### 3.2.648 2021-08-26

- T3776 (default): Rename FRR daemon restart op-mode commands
- T3739 (feature): policy: route-map: add EVPN match support

### 3.2.649 2021-08-25

- T3773 (bug): Delete the "show system integrity" command (to prepare for a re-implementation)
- T3775 (bug): Typo in generated Strongswan VPN-config

### 3.2.650 2021-08-24

- T3772 (bug): VRRP virtual interfaces are not shown in show interfaces

### 3.2.651 2021-08-23

- T3769 (feature): Containers: Network Bridging

### 3.2.652 2021-08-22

- T3090 (feature): Move 'adjust-mss' firewall options to the interface section.
- T3765 (default): container: additional op-mode commands

### 3.2.653 2021-08-20

- T1950 (default): Store VyOS configuration syntax version data in JSON file

### 3.2.654 2021-08-19

- T3751 (bug): pki generate ca add new line after passphrase
- T3764 (bug): Unconfigurable IKE and ESP lifetime
- T3234 (bug): multi\_to\_list fails in certain cases, with root cause an element redundancy in XML interface-definitions
- T3732 (feature): override-default helper should support adding defaultValues to default less nodes
- T3759 (default): [L3VPN] VPNv4/VPNv6 add commands

### 3.2.655 2021-08-18

- T3752 (bug): generate pki certificate file xxx doesn't touch file

### 3.2.656 2021-08-16

- T3738 (default): openvpn fails if server and authentication are configured
- T1594 (bug): l2tpv3 error on IPv6 local-ip

### 3.2.657 2021-08-15

- T3756 (default): VyOS generates invalid QR code for wireguard clients
- T3757 (default): OSPF: add support to configure the area at an interface level

### 3.2.658 2021-08-14

- T3745 (feature): op-mode IPsec show vpn ipse sa sorting

### 3.2.659 2021-08-13

- T3749 (bug): V4/V6 Counters in network container validation aren't being reset
- T3728 (bug): FRR not respect configured RD and RT for L3VNI
- T3727 (bug): VPN IPsec ESP proposal and ESP presented in config mismatch
- T3740 (bug): HTTPs API breaks when the address is IPv6

### 3.2.660 2021-08-12

- T3731 (bug): `verify_accel_ppp_base_service` return wrong config error for SSP
- T3405 (feature): PPPoE server unit-cache
- T2432 (default): `dhcpd`: Can't create new lease file: Permission denied
- T3746 (feature): Inform users logging into the system about a pending reboot
- T3744 (default): Dns forwarding statistics formatting missing a new line

### 3.2.661 2021-08-11

- T3709 (feature): `Snmp`: Allow enable MIDs/OIDs `ipCidrRouteTable`

### 3.2.662 2021-08-09

- T3720 (bug): IPsec set vti secondary address cause interface disable

### 3.2.663 2021-08-08

- T3705 (bug): IPsec: VTI interface does not honor `default-esp-group`
- T2027 (bug): `get_config_dict` is failing when the configuration section is empty/missing

### 3.2.664 2021-08-05

- T3719 (bug): Restart vpn shows some missed files

### 3.2.665 2021-08-04

- T3704 (feature): Add ability to interact with Areca RAID adapters
- T3718 (bug): VPN IPsec IKE group by default not use DH-group 2

### 3.2.666 2021-08-02

- T3601 (default): Error in ssh keys for vmware cloud-init if ssh keys is left empty.

### 3.2.667 2021-08-01

- T3707 (bug): Ping incorrect ip host checks

### 3.2.668 2021-07-31

- [T3716](#) (feature): Linux kernel parameters ignore\_routes\_with\_link\_down- ignore disconnected routing connections

### 3.2.669 2021-07-30

- [T1176](#) (default): FRR - BGP replicating routes
- [T1210](#) (feature): About IKEv2 IPSec VPN remote access

### 3.2.670 2021-07-23

- [T3699](#) (bug): login: verify selected "system login user" name is not already used by the base system.
- [T3698](#) (default): Support bridge monitoring

### 3.2.671 2021-07-13

- [T3679](#) (default): Point the unexpected exception message link to the new rolling release location

### 3.2.672 2021-07-11

- [T3665](#) (bug): Missing VRF support for VxLAN but already documented

### 3.2.673 2021-07-10

- [T3636](#) (feature): SSTP / L2TP ipv6 support broken

### 3.2.674 2021-07-09

- [T3667](#) (bug): brctl is damaged

### 3.2.675 2021-07-06

- [T3660](#) (feature): Conntrack-Sync configuration command to specify destination udp port for peer

### 3.2.676 2021-07-03

- [T57](#) (enhancement): Make it possible to disable the entire IPsec peer

### 3.2.677 2021-07-01

- [T3658](#) (feature): Add support for dhcpdv6 fixed-prefix6
- [T2035](#) (bug): Executing vyos-smoketest multiple times makes ssh test fail on execution

### 3.2.678 2021-06-29

- [T3593](#) (bug): PPPoE server called-sid format does not work
- [T1441](#) (feature): Add support for IPSec XFRM interfaces

### 3.2.679 2021-06-25

- [T3641](#) (feature): Upgrade base system from Debian Buster -> Debian Bullseye
- [T3649](#) (feature): Add bonding additional hash-policy

### 3.2.680 2021-06-23

- [T3647](#) (feature): Bullseye: gcc defaults to passing --as-needed to linker

### 3.2.681 2021-06-22

- [T3629](#) (bug): IPoE server shifting address in the range
- [T3645](#) (feature): Bullseye: ethtool changed output for ring-buffer information

### 3.2.682 2021-06-21

- [T3563](#) (default): commit-archive breaks with IPv6 source addresses

### 3.2.683 2021-06-20

- [T3637](#) (bug): vrf: bind-to-all didn't work properly
- [T3639](#) (default): GCC preprocessor clobbers C comments

### 3.2.684 2021-06-19

- T3633 (feature): Add LRO offload for interface ethernet

### 3.2.685 2021-06-18

- T3599 (default): Migrate NHRP to XML/Python

### 3.2.686 2021-06-17

- T3624 (feature): BGP: add support for extended community bandwidth definition

### 3.2.687 2021-06-16

- T3623 (default): Fix for dummy interface option in the operational command "clear interfaces dummy"
- T3630 (feature): op-mode: add "show version kernel" command

### 3.2.688 2021-06-13

- T3620 (feature): Rename WWAN interface from wirelessmodem to wwan to use QMI interface
- T2173 (feature): Add the ability to use VRF on VTI interfaces
- T3622 (feature): WWAN: add support for APN authentication
- T3606 (bug): SNMP unknown notification OID
- T3621 (bug): PPPoE interface does not validate if password is supplied when username is set

### 3.2.689 2021-06-12

- T3611 (bug): WWAN interface (MC7710) no longer works on Kernel 5.10
- T1534 (bug): IPSec w/ IKEv2 Invalid local-address "any"
- T3616 (bug): Update to FastAPI causes regression in vyos-http-api-server

### 3.2.690 2021-06-11

- T3614 (bug): Container network name with hyphen fail

### 3.2.691 2021-06-10

- T3250 (bug): PPPoE server: wrong local usernames
- T3138 (bug): ddclient improperly updated when apply rfc2136 config
- T2645 (default): Editing route-map action requires adding a new rule

### 3.2.692 2021-06-08

- T3605 (default): Allow to set prefer-global for ipv6-next-hop
- T3607 (feature): [route-map] set ipv6 next-hop prefer-global
- T3289 (bug): No description for node "service" conf-mode

### 3.2.693 2021-06-07

- T3461 (bug): OpenConnect Server redundancy check
- T3455 (bug): system users can not be added in "edit"
- T3588 (default): IPSec: migrate no longer available options from CLI which are now hardcoded/enabled in strongSwan

### 3.2.694 2021-06-06

- T842 (feature): Adopt VyOS CLI to latest StrongSwan options and deprecated Keywords

### 3.2.695 2021-06-04

- T3595 (default): Cannot create new VTI interface
- T3592 (feature): Set default TTL 64 for tunnels

### 3.2.696 2021-06-03

- T3384 (feature): Support UDP bandwidth testing

### 3.2.697 2021-06-02

- T3233 (bug): Interface redirect to dum0

### 3.2.698 2021-06-01

- T3585 (default): Fix NHRP module for updated interfaces tunnel syntax
- T3594 (bug): Disable by default service strongswan-starter

### 3.2.699 2021-05-30

- T3518 (bug): Warning messages when using SCP commit-archive
- T3093 (default): Add xml for vpn ipsec
- T1866 (bug): Commit archive over SFTP doesn't work with non-standard ports
- T3590 (feature): bgp: add option for limiting maximum number of prefixes to be sent to a peer
- T3589 (feature): op-mode: support clearing out logfiles from CLI
- T2641 (feature): Rewrite vpn ipsec OP commands in new style XML syntax
- T3351 (feature): Installer checking MD5 checksums on the ISO image

### 3.2.700 2021-05-29

- T1944 (bug): FRR: Invalid route in BGP causes update storm, memory leak, and failure of Zebra
- T1888 (feature): Update to StrongSwan 5.9.1

### 3.2.701 2021-05-27

- T3561 (feature): router-advert: support advertising specific routes
- T2669 (bug): DHCP-server overlapping ranges.

### 3.2.702 2021-05-26

- T3540 (bug): Keepalived memory utilisation issue when constantly getting its state in JSON format

### 3.2.703 2021-05-24

- T3575 (bug): pseudo-ethernet: must check source-interface MTU
- T3571 (bug): Broken Show Tab Complete
- T3555 (bug): GRE TAP tunnel does not silent fragment packets / kernel fix available
- T3576 (bug): ISIS does not support IPV6

### 3.2.704 2021-05-23

- T3570 (default): Prevent setting of a larger MTU on child interfaces
- T3573 (bug): as-path-prepend Description Invalid
- T3572 (feature): Basic Drive Diagnostic Tools

### 3.2.705 2021-05-22

- T3564 (default): Multiple BGP Confederation Peers Not Allowed

### 3.2.706 2021-05-21

- T3551 (bug): QoS control failure of VLAN sub interface

### 3.2.707 2021-05-20

- T3554 (feature): Add area-type stub for ospfv3
- T3565 (feature): sysctl: rewrite in XML and Python and drop from vyatta-cfg-system

### 3.2.708 2021-05-19

- T3562 (feature): Update Accel-PPP to a newer revision
- T3559 (feature): Add restart op-command for OpenConnect Server

### 3.2.709 2021-05-18

- T3525 (default): VMWare resume script syntax errors

### 3.2.710 2021-05-15

- T3549 (bug): DHCPv6 "service dhcpv6-server global-parameters name-server" is not correctly exported to dhcpdv6.conf when multiple name-server entries are present
- T3532 (bug): Not possible to change ethertype after interface creation
- T3550 (bug): Router-advert completion typo
- T3547 (feature): conntrackd: remove deprecated config options
- T3535 (feature): Rewrite vyatta-conntrack-sync in new XML and Python flavor

### 3.2.711 2021-05-14

- T3346 (bug): nat 4-to-5 migration script fails when a 'source' or 'destination' node exists but there are no rules
- T3248 (default): Deal with VRRP mode-force command that exists in 1.2 but not in 1.3
- T3426 (default): add support for script arguments to vyos-configd

### 3.2.712 2021-05-13

- T3539 (bug): Typo in RPKI interface definition
- T439 (feature): local PBR support
- T3544 (feature): DHCP server should validate configuration before applying it
- T3543 (feature): Support for setting lacp\_rate on LACP bonded interfaces

### 3.2.713 2021-05-12

- T3302 (default): Make vyos-configd relay stdout from scripts to the user's console
- T3542 (bug): udev net.rules not installed in image since may 2nd

### 3.2.714 2021-05-10

- T3374 (bug): IPv6 GRE Tunnel issues

### 3.2.715 2021-05-09

- T3530 (bug): BGP peer-group can't contain a hyphen

### 3.2.716 2021-05-06

- T3523 (bug): VRF BGP daemon route-map command missing
- T3519 (bug): Cannot add / assign L2TPv3 to vrf

### 3.2.717 2021-05-05

- T3520 (bug): Cannot add tunnel interface to isis within vrf
- T3335 (bug): Some OSPFv3 show commands do not work

### 3.2.718 2021-05-04

- T3504 (feature): BGP Per Peer Graceful Restart

### 3.2.719 2021-05-02

- T3511 (bug): Update libnss-mapuser and libpam-radius packages from CUMULUS Linux

### 3.2.720 2021-05-01

- T3379 (feature): Add global-parameters name-server for dhcpv6-server
- T3491 (default): Change Kernel HZ to 1000

### 3.2.721 2021-04-29

- T3503 (bug): "route-reflector-client" fails when "remote-as" is "internal"
- T3502 (bug): "system ip multipath layer4-hashing" doesn't work

### 3.2.722 2021-04-28

- T3473 (bug): IPSec op-mode show sa error

### 3.2.723 2021-04-27

- T2946 (bug): Calling 'stty\_size' causes show interfaces API to fail

### 3.2.724 2021-04-25

- T3490 (bug): priority inversion on PBR "policy route" create, breaks default route from dhcp (live iso)
- T3468 (bug): Tunnel interfaces aren't suggested as being available for bridging (regression)
- T3497 (bug): Prefix list with rule containing only action is not detected as error during parse
- T3492 (bug): BGP Configuration Migration failed (badly!) from rolling 202102240218 to rolling 202104221210
- T1802 (feature): Wireguard QR code in cli for mobile devices

### 3.2.725 2021-04-24

- T3472 (bug): `commit-confirm` script not found
- T3439 (bug): `Commit-archive` location not working for `scp`

### 3.2.726 2021-04-23

- T3395 (bug): WAN load-balancing fails with `nexthop dhcp`
- T3290 (bug): Disabling GRE `conntrack` module fails

### 3.2.727 2021-04-20

- T3488 (bug): Specifying an invalid "interface address" like `dhcp` leads to commit error

### 3.2.728 2021-04-18

- T3481 (default): Exclude tag node values from key mangling
- T3475 (bug): XML dictionary cache unable to process `syntaxVersion` elements

### 3.2.729 2021-04-17

- T3470 (bug): `as-override` isn't applied to `frr`

### 3.2.730 2021-04-15

- T3386 (bug): PPPoE-server don't start with local authentication
- T3190 (feature): Unable to subtract value from local-preference in route-map

### 3.2.731 2021-04-14

- T3398 (bug): Can't commit
- T3055 (bug): op-mode incorrect naming for ipsec policy-based tunnels

### 3.2.732 2021-04-13

- T3436 (feature): Refactoring `ospf` op-mode for support `vrf`
- T3434 (feature): Refactoring `bgp` op-mode for support `vrf`

### 3.2.733 2021-04-12

- T3454 (enhancement): dhclient reject option
- T3328 (bug): Bgp not possible to delete bgp route-map

### 3.2.734 2021-04-10

- T3460 (bug): bgp, Configuration FRR failed while committing code

### 3.2.735 2021-04-09

- T3464 (bug): OSPF: route-map names containing a hyphen are not "found"

### 3.2.736 2021-04-08

- T3462 (default): show ipv6 bgp -- missing
- T3463 (bug): Prevent IPv4 Route exchange with IPv6 neighbors

### 3.2.737 2021-04-05

- T3438 (bug): VRF: removing vif which belongs to a vrf, will delete the entire vrf from the operating system
- T3418 (bug): BGP: system wide known interface can not be used as neighbor

### 3.2.738 2021-04-04

- T3457 (feature): Output the "monitor log" command in a colorful way

### 3.2.739 2021-03-31

- T3445 (bug): vyos-1x build include not all nodes

### 3.2.740 2021-03-30

- T3448 (bug): Loading vyos on a system without xdp installed fails

### 3.2.741 2021-03-29

- T3415 (feature): bridge: add support for isolated interfaces (private-vlan)
- T1711 (feature): BGP - migrate from tagNode to node (remove ASN from tagNode)

### 3.2.742 2021-03-28

- T3440 (bug): HTTP API: give uvicorn time to initialize before restarting Nginx proxy

### 3.2.743 2021-03-27

- T3423 (bug): Cannot create ipv4 static route for default gateway in vrf

### 3.2.744 2021-03-26

- T3412 (default): HTTP API: move to FastAPI as web framework
- T2397 (feature): HTTP API: export OpenAPI definition

### 3.2.745 2021-03-24

- T3419 (bug): show interfaces | strip-private fails

### 3.2.746 2021-03-22

- T3284 (bug): merge/load fail silently if unable to resolve host

### 3.2.747 2021-03-21

- T3417 (default): ISIS: provide per VRF instance support
- T3416 (bug): NTP: when running inside a VRF op-mode commands do not work

### 3.2.748 2021-03-20

- T3392 (bug): vrrp over dhcp default route bug (unexpected vrf)
- T3373 (feature): Upgrade to SaltStack version 3002.5
- T3329 (default): "system conntrack ignore" rules can no longer be created due to an iptables syntax change
- T3300 (feature): Add DHCP default route distance
- T3306 (feature): Extend set route-map aggregator as to 4 Bytes

### 3.2.749 2021-03-18

- T3411 (default): Extend the redirect\_stdout context manager in vyos-configd to redirect stdout from subprocesses
- T3271 (bug): qemu-kvm grub issue

### 3.2.750 2021-03-17

- **T3413** (bug): Configuring invalid IPv6 EUI64 address results in "OSError: illegal IP address string passed to inet\_pton"

### 3.2.751 2021-03-14

- **T3345** (default): BGP: add per VRF instance support
- **T3344** (default): Per VRF dynamic routing support
- **T3325** (bug): Bgp listen-range wrong commit message
- **T1513** (default): Move OSPF and RIP interface configuration under protocols

### 3.2.752 2021-03-13

- **T3406** (bug): tunnel: interface no longer supports specifying encaps limit none - or migrator is missing
- **T3407** (bug): console-server: do not allow to spawn a console-server session on serial port used by "system console"

### 3.2.753 2021-03-11

- **T3305** (bug): Ingress qdisc does not work anymore in 1.3-rolling-202101 snapshot
- **T2927** (bug): isc-dhcpd release and expiry events never execute

### 3.2.754 2021-03-09

- **T3382** (bug): Error creating Console Server

### 3.2.755 2021-03-08

- **T3387** (bug): Command "Monitor vpn ipsec" is not working

### 3.2.756 2021-03-07

- **T3388** (bug): show interfaces doesn't display pppoeX
- **T3211** (feature): ability to redistribute ISIS into other routing protocols

### 3.2.757 2021-03-04

- T3377 (bug): show interfaces throws error

### 3.2.758 2021-03-02

- T3375 (bug): Interface becomes up at boot even when disabled

### 3.2.759 2021-02-28

- T3370 (bug): dhcp: Invalid domain name "private"
- T3369 (feature): VXLAN: add IPv6 underlay support
- T3363 (bug): VyOS-Build interactive prompt when using Podman
- T3320 (bug): Bgp neighbor peer-group without peer-group fail

### 3.2.760 2021-02-27

- T3365 (bug): Bgp neighbor interface ordering for remote-as
- T3225 (bug): Adding a BGP neighbor with an address on a local interface throws a `vyos.frr.CommitError: Configuration FRR failed while committing code: ''`
- T3368 (feature): macsec: add support for gcm-aes-256 cipher
- T3173 (feature): Need 'nopmtudisc' option for tunnel interface

### 3.2.761 2021-02-26

- T3324 (bug): Bgp space in the password
- T3357 (default): HTTP-API redirect from http correct https port
- T3323 (bug): Bgp ttl-security and ebgp-multihop fail

### 3.2.762 2021-02-24

- T3303 (feature): Change welcome message on boot

### 3.2.763 2021-02-22

- T3322 (bug): Bgp neighbor timers not applied to FRR config
- T3327 (bug): OSPFv3: Cannot add dummy interface

### 3.2.764 2021-02-21

- T3331 (bug): Bgp unsuppress-map should be as "value leafNode"
- T3330 (bug): Bgp capability orf prefix-list fail
- T3163 (feature): ethernet ring-buffer can be set with an invalid value

### 3.2.765 2021-02-19

- T3326 (bug): OSPFv3: Cannot add L2TPv3 interface
- T3332 (bug): BGP unnumbered - UnboundLocalError: local variable 'peer\_group' referenced before assignment

### 3.2.766 2021-02-18

- T3259 (default): many dn timer rules makes the vyos http api crash, even showConfig op timeouts

### 3.2.767 2021-02-17

- T3312 (feature): SolarFlare NICs support

### 3.2.768 2021-02-16

- T3313 (bug): ospfv3 interface missing options
- T3318 (feature): Update Linux Kernel to v5.4.208 / 5.10.142

### 3.2.769 2021-02-15

- T3311 (bug): BGP Error: Remote AS must be set for neighbor or peer-group

### 3.2.770 2021-02-14

- T2848 (feature): bgp-add-path configuration options

### 3.2.771 2021-02-12

- T3301 (bug): Wrong format and valueHelp for policy as-path-list regex

### 3.2.772 2021-02-11

- T3281 (default): Rewrite protocol RIPng [conf-mode] to new XML/Python style
- T3282 (default): Add XML for [conf-mode] RIPng
- T3279 (default): Rewrite protocol STATIC [op-mode] to new XML/Python style
- T3297 (bug): Optimize irrelevant error stack hints

### 3.2.773 2021-02-08

- T3295 (feature): Update Linux Kernel to v5.4.96 / 5.10.14

### 3.2.774 2021-02-05

- T3030 (feature): Support ERSPAN Tunnel Protocol

### 3.2.775 2021-02-04

- T3283 (feature): Support for IPv4 neigh tables
- T3280 (default): Add XML for [conf-mode] STATIC

### 3.2.776 2021-02-03

- T3278 (feature): Add XML for "protocols vrf" [conf-mode]
- T3239 (default): XML: override 'defaultValue' for mtu of certain interfaces; remove workarounds
- T2910 (feature): XML: generator should support override of variables

### 3.2.777 2021-02-02

- T3018 (bug): Unclear behaviour when configuring vif and vif-s interfaces
- T3255 (default): Rewrite protocol RPKI to new XML/Python style
- T3263 (feature): OSPF Hello subsecond timer

### 3.2.778 2021-01-31

- T3276 (feature): Update Linux Kernel to v5.4.94 / 5.10.12

### 3.2.779 2021-01-30

- T3240 (feature): Support per-interface DHCPv6 DUIDs
- T3273 (default): PPPoE static default-routes deleted on interface down when not added by interface up

### 3.2.780 2021-01-29

- T3261 (bug): Does not possible to disable pppoe client interface.
- T3272 (default): OSPF: interface config is not removed

### 3.2.781 2021-01-27

- T3257 (feature): tcpdump supporting complete protocol
- T3244 (default): Rewrite protocol OSPFv3 to new XML/Python style

### 3.2.782 2021-01-26

- T3251 (bug): PPPoE client trying to authorize with the wrong username
- T3256 (default): Add XML for protocol RPKI [conf-mode]

### 3.2.783 2021-01-25

- T3249 (feature): Support operation mode forwarding table output

### 3.2.784 2021-01-24

- T3227 (bug): Latest releases don't work with RPKI (crash)
- T3230 (bug): RPKI can't be deleted
- T3221 (bug): FRR config
- T3245 (default): Add XML for protocol ospfv3 [conf-mode]

### 3.2.785 2021-01-23

- T3236 (default): Add XML for [conf-mode] OSPF

### 3.2.786 2021-01-17

- T3222 (bug): Typo in BGP dampening description
- T3226 (bug): Repair bridge smoke test damage

### 3.2.787 2021-01-16

- T3215 (bug): Operational command "show ipv6 route" is broken
- T3157 (bug): salt-minion fails to start due to permission error accessing /root/.salt/minion.log
- T3137 (feature): Let VLAN aware bridge approach the behavior of professional equipment

### 3.2.788 2021-01-15

- T3210 (feature): ISIS three-way-handshake
- T3184 (feature): Add correct descriptions for BGP neighbors

### 3.2.789 2021-01-14

- T3213 (bug): show interface command python error

### 3.2.790 2021-01-12

- T3205 (bug): Does not possible to configure tunnel mode gre-bridge

### 3.2.791 2020-12-20

- T3132 (feature): Enable egress flow accounting

### 3.2.792 2020-11-29

- T2297 (feature): NTP add support for pool configuration

## 3.3 1.3 Equuleus

### 3.3.1 2024-04-25

- T6249 (default): ISO builder fails because of changed buster-backport repository

### 3.3.2 2024-04-23

- T6261 (default): Typo in op\_mode connect\_disconnect print statement for check\_ppp\_running

### 3.3.3 2024-04-17

- T6243 (bug): Update vyos-http-api-tools for package idna security advisory

### 3.3.4 2024-04-12

- T3437 (bug): BGP Confederation Addition Causes Error

### 3.3.5 2024-04-10

- T6124 (bug): Docker equuleus build image doesn't build due to fpm

### 3.3.6 2024-04-08

- T6196 (bug): Route-map and summary-only do not work in BGP aggregation at the same time

### 3.3.7 2024-04-07

- T1244 (default): Support for StartupResync in conntrackd

### 3.3.8 2024-04-05

- T2590 (bug): DHCPv6 not updating nameservers and search domains since replacing isc-dhcp-client with WIDE dhcp6c

### 3.3.9 2024-04-04

- T4146 (bug): Nginx should not listen on port 80
- T1976 (default): deleting address-family under neighbor will disable neighbor
- T5625 (default): "restart vpn" does not work if ipsec-interfaces is not set
- T3020 (bug): The "scp" example is wrong in the bash-completion for "set system config-management commit-archive location"
- T2250 (default): vyos-build "make iso" error if configure was ran outside of the docker container
- T2139 (default): openvpn: allow "dh-file none" to disable DH for ECDH keys
- T2014 (default): Use vendor specific NTP Pool hostname
- T1118 (bug): Obsolete "utc" option in time selector in firewall
- T948 (feature): integrate aws cloud watch scripts into AMI

### 3.3.10 2024-04-02

- T6150 (bug): Impossible to set a static IP address via Radius in IPoE

### 3.3.11 2024-04-01

- T6193 (bug): dhcp-client: invalid warning "is not a DHCP interface but uses DHCP name-server option" for VLAN interfaces

### 3.3.12 2024-03-22

- T6110 (bug): dhcp server - If failover is defined, range is required
- T5624 (default): Remove /etc/debian\_version from the image

### 3.3.13 2024-03-11

- T2998 (bug): SNMP v3 oid "exclude" option doesn't work
- T6096 (bug): Config commits are not synced properly because `vyos-sync` is deleted by `vyos-router`
- T6057 (feature): Add ability to disable syslog for `conntrackd`
- T5504 (feature): Keepalived VRRP ability to set more than one peer-address

### 3.3.14 2024-03-07

- T3992 (bug): Traceback on adding interface to bridge with configured ip address

### 3.3.15 2024-03-06

- T6088 (bug): Configuration corrupted after saving and powercut or force reboot

### 3.3.16 2024-02-16

- T2113 (bug): OpenVPN Options error: you cannot use `--verify-x509-name` with `--compat-names` or `--no-name-remapping`
- T5418 (bug): PPPoE-Server Client IP pool Subnet

### 3.3.17 2024-02-15

- T2612 (bug): HTTPS API, changing API key fails but goes through
- T656 (enhancement): Rewrite wirelessmodem in new style XML interface definition

### 3.3.18 2024-02-14

- T2044 (bug): RPKI doesn't boot properly

### 3.3.19 2024-02-08

- T6014 (feature): Bump keepalived version

### 3.3.20 2024-02-07

- T6017 (bug): Update vyos-http-api-tools for security advisory

### 3.3.21 2024-02-02

- T5914 (bug): CVE-2023-48795 - Terrapin vulnerability
- T5739 (bug): Password recovery does not work if public keys are configured

### 3.3.22 2024-02-01

- T5967 (bug): Multi-hop BFD connections can't be established; please add minimum-ttl option.

### 3.3.23 2024-01-22

- T4721 (feature): Static IPv6 Route Tags Missing

### 3.3.24 2024-01-20

- T5187 (bug): Update Realtek r8152 driver
- T5182 (bug): Update Intel ice driver
- T5180 (bug): initramfs-tools ignores firmware from updates directory
- T4990 (bug): Commit results may not be properly saved if power is cut immediately after a successful commit
- T4039 (feature): Rsyslog to use 'protocol23format' for protocol UDP
- T3813 (bug): Some custom sysctl parameters can't be applied bug
- T2579 (feature): The root task for VRF features
- T2546 (feature): The root task for rewriting [op-mode] to XML
- T2452 (default): Serial console related issues

### 3.3.25 2024-01-19

- T5543 (bug): Fix source address handling in static joins

### 3.3.26 2024-01-14

- T5715 (bug): IPsec VPN: restart vpn is not working

### 3.3.27 2024-01-13

- T5924 (bug): Build cannot pass the smoketest dialup-router-medium-vpn

### 3.3.28 2024-01-11

- T5275 (default): Add op mode commands for exporting certificates to PEM files with correct headers
- T5274 (default): Add a deprecation warning for OpenVPN site-to-site with pre-shared secret
- T3191 (bug): PAM RADIUS freezing when accounting does not configured on RADIUS server

### 3.3.29 2024-01-10

- T4646 (bug): USB serial output console does not work
- T4466 (bug): intel i225-v nic does not detect link after boot
- T4222 (feature): Support for TWAMP as round-trip metric
- T1369 (bug): GCP Networking Failure

### 3.3.30 2024-01-09

- T3242 (bug): PPPoE Server overhead on virtual interfaces creation
- T2755 (default): Requirements for partial interface setup
- T2494 (bug): systemd dependencies issues
- T2343 (feature): Disable memory ballooning in VM templates
- T2254 (default): Provide more information on the build branch in the version data
- T2223 (feature): convert operational show interfaces to python/XML
- T1925 (bug): DMVPN is always listed as down in "show vpn ipsec sa"
- T1297 (feature): Add GARP settings to VRRP/keepalived

### 3.3.31 2024-01-08

- T5318 (bug): Security Vulnerabilities for VyOS 1.3.3
- T3980 (bug): vrrp transition-script validator makes warning fatal and also causes a python NameError exception
- T2799 (feature): VyOS Certificates Manager

### 3.3.32 2023-12-29

- T5852 (bug): Reboots fail with eapol WAN interface

### 3.3.33 2023-12-22

- T4760 (bug): VyOS does not support running multiple instances of DHCPv6 clients

### 3.3.34 2023-12-21

- T5714 (bug): IPSec VPN: op-mode: "show log vpn" does not show results
- T3039 (feature): Resize a root partition and filesystem automatically during deployment in virtual environments
- T2404 (bug): Cannot change MTU
- T2353 (bug): Interface [conf\_mode] errors parent task
- T5796 (bug): Openconnect - HTTPS security headers are missing

### 3.3.35 2023-12-19

- T2116 (feature): Processing configuration via Cloud-init User-Data

### 3.3.36 2023-12-18

- T2191 (feature): Using tallow to block sshd probes

### 3.3.37 2023-12-15

- T5824 (bug): busybox cannot connect some websites from initramfs

### 3.3.38 2023-12-12

- [T5817](#) (bug): Show openvpn server fails in some cases
- [T5413](#) (default): Deny the opportunity to use one public/private key pair on both wireguard peers.

### 3.3.39 2023-11-30

- [T4601](#) (bug): dhcp : relay agent IP address issue.

### 3.3.40 2023-11-28

- [T5777](#) (bug): frr: backport and upstream recent bgpd daemon crashes

### 3.3.41 2023-11-27

- [T5763](#) (bug): Fix imprecise check for remote file name in vyos-load-config.py

### 3.3.42 2023-11-25

- [T5655](#) (bug): commit-archive: Ctrl+C should not error out with stack trace, signal should be caught

### 3.3.43 2023-11-24

- [T5402](#) (bug): VRRP router with rfc3768-compatibility sends multiple ARP replies

### 3.3.44 2023-11-22

- [T5578](#) (bug): "ikev2-reauth" description contains outdated information

### 3.3.45 2023-11-15

- [T5661](#) (enhancement): Add show show ssh dynamic-protection attacker and show log ssh dynamic-protection
- [T1276](#) (bug): dhcp relay + VLAN fails

### 3.3.46 2023-11-07

- T5586 (feature): Disable by default SNMP for Keepalived VRRP

### 3.3.47 2023-11-06

- T4269 (feature): node.def generator should automatically add default values

### 3.3.48 2023-10-26

- T5684 (bug): services using VRF generates the error "Failed to load BPF prog: 'Operation not permitted'" when the system boots.
- T5594 (bug): VRRP - Error if using IPv6 Link Local as hello source address

### 3.3.49 2023-10-21

- T5670 (bug): bridge: missing member interface validator
- T5191 (default): Replace underscores with hyphens in command-line options generated by vyos.opmode
- T4402 (bug): OpenVPN client-ip-pool option is broken
- T2719 (feature): Standardized op mode script structure

### 3.3.50 2023-10-19

- T5669 (bug): VXLAN interface changing port does not work

### 3.3.51 2023-10-17

- T5235 (bug): SSH keys with special characters cannot be applied via Cloud-init

### 3.3.52 2023-10-08

- T5630 (feature): pppoe: allow to specify MRU in addition to already configurable MTU

### 3.3.53 2023-10-06

- T5576 (feature): Add bgp remove-private-as all option

### 3.3.54 2023-10-04

- T5632 (feature): Add jq package to parse JSON files

### 3.3.55 2023-09-25

- T5533 (bug): Keepalived VRRP IPv6 group enters in FAULT state

### 3.3.56 2023-09-20

- T5271 (default): Add support for peer-fingerprint to OpenVPN

### 3.3.57 2023-09-11

- T5557 (bug): bgp: Use treat-as-withdraw for tunnel encapsulation attribute  
CVE-2023-38802
- T3424 (default): PPPoE IA-PD doesn't work in VRF

### 3.3.58 2023-09-10

- T5555 (bug): Fix timezone migrator (system 13-to-14)
- T5545 (bug): sflow is not working

### 3.3.59 2023-09-08

- T4426 (default): Add arpwatch to the image

### 3.3.60 2023-09-05

- T5524 (feature): Add config directory to liveCD
- T2958 (bug): DHCP server doesn't work from a live CD
- T5428 (bug): dhcp: client renewal fails when running inside VRF

### 3.3.61 2023-09-04

- T5506 (bug): Container bridge interfaces do not have a link-local address

### 3.3.62 2023-08-31

- T5190 (feature): Cloud-Init cannot fetch Meta-data on machines where the main Ethernet interface is not eth0
- T5140 (bug): Firewall network-group problems
- T4895 (bug): Tag nodes are overwritten when configured by Cloud-Init from User-Data
- T4874 (default): Add Warning message to Equuleus
- T4855 (bug): Trying to create more than one tunnel of the same type to the same address causes unhandled exception
- T4776 (bug): NVME storage is not detected properly during installation
- T3546 (feature): Add support for running scripts on PPPoE server session events
- T738 (feature): Add local-port and resolver port options for powerdns in CLI configuration tree

### 3.3.63 2023-08-30

- T5221 (bug): BGP as-override behavior differs from new FRR and other vendors
- T4933 (default): Malformed lines cause vyos.util.colon\_separated\_to\_dict fail with a nondescript error
- T4790 (bug): RADIUS login does not work if sum of timeouts more than 50s
- T4475 (bug): route-map does not support ipv6 peer
- T4459 (bug): API service with VRF doesn't work in 1.3.1
- T4407 (bug): Network-config v2 is broken in Cloud-init 22.1 and VyOS 1.3
- T4113 (bug): Incorrect GRUB configuration parsing
- T1764 (bug): Use lists instead of whitespace-separated strings in vyos.config
- T4121 (bug): Nameservers from DHCP client cannot be used in specific cases
- T4151 (feature): IPV6 local PBR Support
- T4306 (default): Do not check for dirty repository when building release images

### 3.3.64 2023-08-29

- T3940 (bug): DHCP client does not remove IP address when stopped by the 02-vyos-stopdhclient hook
- T3713 (default): Create a meta-package for user utilities
- T3339 (bug): Cloud-Init domain search setting not applied
- T2640 (feature): Running VyOS inside Docker containers
- T3577 (bug): Generating vpn x509 key pair fails with command not found

### 3.3.65 2023-08-28

- T4745 (bug): CLI TAB issue with values with '-' at the beginning in conf mode
- T2611 (bug): Prefix list names are shared between ipv4 and ipv6
- T2296 (default): Upgrade WALinux to 2.2.41
- T2123 (default): Configure 3 NTP servers
- T469 (bug): Problem after commit with errors

### 3.3.66 2023-08-25

- T4412 (bug): commit archive: reboot not working with sftp
- T3702 (feature): Policy: Allow routing by fwmark
- T3536 (default): Unable to list all available routes

### 3.3.67 2023-08-24

- T5006 (bug): Http api segfault with concurrent requests
- T5305 (bug): REST API configure operation should not be defined as async

### 3.3.68 2023-08-23

- T5387 (feature): dhcp6c: add a no release option

### 3.3.69 2023-08-20

- T5470 (bug): wlan: can not disable interface if SSID is not configured

### 3.3.70 2023-08-17

- T5486 (bug): Service dns dynamic cannot pass the smoketest
- T5223 (bug): tunnel key doesn't clear

### 3.3.71 2023-08-15

- T5273 (default): Add op mode commands for displaying certificate details and fingerprints
- T5270 (default): Make OpenVPN `tls dh-params` optional

### 3.3.72 2023-08-10

- T5329 (bug): Wireguard interface as GRE tunnel source causes configuration error on boot

### 3.3.73 2023-07-24

- T5354 (feature): Add sshguard to protect against brut-forces for 1.3

### 3.3.74 2023-07-17

- T2051 (bug): Throughput anomalies

### 3.3.75 2023-07-14

- T305 (default): loadbalancing does not work with one pppoe connection and another connection of either dhcp or static

### 3.3.76 2023-07-13

- T3045 (bug): Changes to Conntrack-Sync don't apply correctly (Multicast->UDP)
- T971 (bug): authentication public-keys options quoting issue

### 3.3.77 2023-07-12

- T5009 (bug): op-mode command: restart dhcp relay-agent not working
- T4927 (bug): Need to change restart to reload-or-restart in Webproxy module
- T3835 (bug): vyos router 1.2.7 snmp Dos bug
- T4959 (feature): Add container registry authentication config for containers
- T425 (feature): AWS CloudWatch monitoring scripts

### 3.3.78 2023-07-11

- T4862 (bug): webproxy domain-block does not work
- T4844 (bug): Incorrect permissions of the safeguard DB directory
- T4262 (bug): install image doesn't respect chosen root partition size
- T3810 (bug): webproxy squidguard rules don't work properly after rewriting to python.
- T1928 (bug): Is the 'Welcome to VyOS' message when using SSH an information leak?
- T4737 (bug): FRRouting/zebra 7.5.1 does not redistribute routes to other protocols
- T3852 (bug): DHCP client issue - interface has two dhclient processes when link is unplugged and then plug again
- T2118 (bug): Failure to boot after power outage due to dirty filesystem and no fsck in initramfs

### 3.3.79 2023-07-05

- T5331 (bug): ath10k\_pci not functioning

### 3.3.80 2023-06-30

- T5315 (feature): vrrp: add support for version 3
- T5313 (bug): UDP broadcast relay - missing verify() that relay interfaces have an IP address assigned

### 3.3.81 2023-06-26

- T5272 (default): Upgrade OpenVPN to 2.6 in Equuleus
- T5265 (bug): WAN load-balancing: missing completion helpers

### 3.3.82 2023-06-25

- T5240 (bug): Service router-advert failed to start radvd with more then 3 name-servers

### 3.3.83 2023-06-21

- T5280 (bug): Update Expired keys (2023-06-08) for PowerDNS

### 3.3.84 2023-06-13

- T5213 (feature): Accel-ppp sending accounting interim updates acct-interim-interval option

### 3.3.85 2023-05-29

- T5243 (bug): Default route is inactive if an interface has multiple ip addresses of the same subnet in 1.3.2 Equuleus

### 3.3.86 2023-05-19

- T5186 (bug): QoS test cannot pass for 1.3

### 3.3.87 2023-05-12

- T2769 (feature): Add VRF support for syslog

### 3.3.88 2023-05-08

- T5212 (bug): snmp community name -error with special carracter

### 3.3.89 2023-04-27

- T5175 (bug): http-api: error in MultiPart parser for FastAPI version >= 0.91.0
- T5176 (bug): http-api: update vyos-http-api-tools for FastAPI security vulnerability

### 3.3.90 2023-04-13

- T5152 (bug): Telegraf agent hostname isn't qualified
- T4727 (feature): Add RADIUS rate limit support to PPTP server
- T4939 (bug): VRRP command no-preempt not work as expected
- T3608 (default): Standardize warnings from configure scripts

### 3.3.91 2023-04-05

- T4975 (bug): CLI does not work after cutting off the power or reset
- T5136 (bug): Possible config corruption on upgrade

### 3.3.92 2023-04-01

- T5047 (bug): Recreate only a specific container

### 3.3.93 2023-03-31

- T5111 (bug): pppd-dns.service startup failed

### 3.3.94 2023-03-29

- T5033 (bug): generate-public-key command fails for address with multiple public keys like GitHub
- T5097 (bug): the operational command "show interfaces ethernet ethx" doesn't reflect a call to 'clear counters'

### 3.3.95 2023-03-21

- T5098 (feature): PPPoE client holdoff configuration

### 3.3.96 2023-03-19

- T4925 (feature): Need to add the possibility to configure Pseudo-Random Functions (PRF) in IKEv2

### 3.3.97 2023-03-16

- T3083 (feature): Add feature event-handler
- T2516 (bug): vyos-container: cannot configure ethernet interface

### 3.3.98 2023-03-09

- T5066 (bug): Different GRE tunnel but same tunnel keys error

### 3.3.99 2023-03-08

- T4381 (default): OpenVPN: Add "Tunnel IP" column in "show openvpn server" operational command
- T4872 (bug): Op-mode show openvpn misses a case when parsing for tunnel IP

### 3.3.100 2023-03-07

- T2838 (bug): Ethernet device names changing, multiple hw-id being added
- T2649 (default): Ensure configuration mode scripts conform to coding guidelines
- T4900 (default): Cache intermediary results of get\_config\_diff in Config instance

### 3.3.101 2023-03-03

- T4625 (enhancement): Update ocserver to current revision (1.1.6)

### 3.3.102 2023-02-28

- T4955 (bug): Openconnect radiusclient.conf generating with extra authserver
- T4219 (feature): support incoming-interface (iif) in local PBR

### 3.3.103 2023-02-25

- T5008 (bug): MACsec CKN of 32 chars is not allowed in CLI, but works fine
- T5007 (bug): Interface multicast setting is invalid
- T5017 (bug): Bug with validator interface-name
- T4992 (bug): Incorrect check is\_local\_address for bgp neighbor with option ip\_nonlocal\_bind set
- T4978 (bug): KeyError: 'memory' container\_config['memory'] on upgrading to 1.4-rolling-202302041536
- T4948 (feature): pppoe: add CLI option to allow definition of host-uniq flag

### 3.3.104 2023-02-22

- T5011 (bug): Some interface drivers don't support min\_mtu and max\_mtu and verify\_mtu check should be skipped

### 3.3.105 2023-02-18

- T4743 (feature): Enable IPv6 address for Dynamic DNS

### 3.3.106 2023-02-16

- T4971 (feature): Radius attribute "Framed-Pool" for PPPoE

### 3.3.107 2023-02-15

- T4993 (bug): Can't delete conntrack ignore rule

### 3.3.108 2023-02-14

- T4999 (feature): vyos.util backport dict\_search\_recursive
- T1993 (feature): Extended pppoe rate-limiter

### 3.3.109 2023-02-13

- T4153 (bug): Monitor bandwidth-test initiate not working

### 3.3.110 2023-02-11

- T2603 (feature): pppoe-server: reduce min MTU

### 3.3.111 2023-02-08

- T1288 (feature): FRR: rewrite staticd backend (/opt/vyatta/share/vyatta-cfg/templates/protocols/static/\*)

### 3.3.112 2023-02-07

- T4117 (bug): Does not possible to configure PoD/CoA for L2TP vpn

### 3.3.113 2023-02-01

- T4970 (default): pin OCaml pcre package to avoid JIT support

### 3.3.114 2023-01-30

- T4954 (bug): DNS cannot be configured via Network-Config v1 received from ConfigDrive / Cloud-Init

### 3.3.115 2023-01-24

- T4949 (feature): Backport "monitor log" and "show log" op-mode definitions from current to equuleus
- T4947 (feature): Support mounting container volumes as ro or rw

### 3.3.116 2023-01-23

- T4798 (default): Migrate the file-exists validator away from Python
- T4683 (enhancement): Add kitty-terminfo package to build
- T4875 (default): Replace Python validator 'interface-name' to avoid Python startup cost
- T4664 (bug): Add validation to reject whitespace in tag node value names

### 3.3.117 2023-01-22

- T4906 (bug): ipsec connections shows only one connection as up

### 3.3.118 2023-01-21

- T4896 (bug): ospfv3: Fix broken not-advertise option
- T4799 (bug): PowerDNS >= 4.7 does not get reloaded by vyos-hostsd

### 3.3.119 2023-01-17

- T4902 (bug): snmpd: exclude container storage from monitoring

### 3.3.120 2023-01-15

- T4832 (feature): dhcp: Add IPv6-only dhcp option support (RFC 8925)
- T4918 (bug): Odd show interface behavior

### 3.3.121 2023-01-09

- T4922 (feature): Add ssh-client source-interface CLI option

### 3.3.122 2023-01-07

- T4884 (bug): Missing a community6 in snmpd config

### 3.3.123 2023-01-05

- T3937 (default): Rewrite "show system memory" in Python to make it usable as a library function

### 3.3.124 2023-01-03

- T4869 (bug): A network with `/32` or `/128` mask cannot be removed from a network-group

### 3.3.125 2022-12-31

- T4898 (feature): Add mtu config option for dummy interfaces

### 3.3.126 2022-12-26

- T4511 (bug): IPv6 DNS lookup
- T4809 (feature): radvd: Allow use of AdvRASrcAddress

### 3.3.127 2022-12-18

- T4709 (bug): TCP MSS clamping broken in equuleus

### 3.3.128 2022-12-15

- T4671 (bug): linux-firmware package is missing symlinks defined in WHENCE file

### 3.3.129 2022-12-04

- T4825 (feature): interfaces veth/veth-pairs -standalone used

### 3.3.130 2022-12-02

- T4122 (bug): interface ip address config missing after upgrade from 1.2.8 to 1.3.0 (when redirect is configured?)
- T1024 (feature): Policy Based Routing by DSCP

### 3.3.131 2022-11-23

- T4793 (feature): Create warning message about disable-route-autoinstall when ipsec vti is used

### 3.3.132 2022-11-21

- T4812 (feature): IPsec ability to show all configured connections

### 3.3.133 2022-11-06

- T2913 (bug): Failure to install fpm while building builder docker image

### 3.3.134 2022-11-04

- T2417 (feature): Python validator cleanup

### 3.3.135 2022-11-01

- T4177 (bug): Strip-private doesn't work for service monitoring

### 3.3.136 2022-10-31

- [T1875](#) (feature): Add the ability to use network address as BGP neighbor (bgp listen range)
- [T4785](#) (feature): snmp: Allow !, @, \* and # in community name

### 3.3.137 2022-10-21

- [T2189](#) (bug): Adding a large port-range will take ~ 20 minutes to commit

### 3.3.138 2022-10-18

- [T4533](#) (bug): Radius clients don't have simple permissions

### 3.3.139 2022-10-13

- [T4312](#) (bug): Telegraf configuration doesn't accept IPs for URL

### 3.3.140 2022-10-12

- [T4730](#) (bug): Conntrack-sync error - listen-address is not the correct type in config as it should be

### 3.3.141 2022-10-11

- [T4680](#) (bug): Telegraf prometheus-client listen-address invalid format

### 3.3.142 2022-10-04

- [T4702](#) (bug): Wireguard peers configuration is not synchronized with CLI
- [T4652](#) (feature): Upgrade PowerDNS recursor to 4.7 series
- [T4648](#) (default): PPPoE: Ignore default router from RA when PPPoE default-route is set to none
- [T4582](#) (default): Router-advert: Preferred lifetime cannot equal valid lifetime in PIOs

### 3.3.143 2022-09-17

- [T4666](#) (bug): EAP-TLS no longer allows TLSv1.0 after T4537, T4584

### 3.3.144 2022-09-15

- T4679 (bug): OpenVPN site-to-site incorrect check for IPv6 local and remote address
- T4630 (bug): Prevent attempts to use the same interface as a source interface for pseudo-ethernet and MACsec at the same time

### 3.3.145 2022-09-12

- T4647 (feature): Add Google Virtual NIC (gVNIC) support

### 3.3.146 2022-09-05

- T4668 (bug): Adding/removing members from bond doesn't work/results in incorrect interface state
- T4628 (bug): ConfigTree() throws ValueError() if tagNode contains whitespaces

### 3.3.147 2022-08-29

- T4653 (bug): Interface offload options are not applied correctly
- T4061 (default): Add util function to check for completion of boot config
- T4654 (bug): RPKI cache incorrect description
- T4572 (bug): Add an option to force interface MTU to the value received from DHCP

### 3.3.148 2022-08-26

- T4642 (bug): proxy: hyphen not allowed in proxy URL

### 3.3.149 2022-08-23

- T4618 (bug): Traffic policy not set on virtual interfaces
- T4538 (bug): Macsec does not work correctly when the interface status changes.

### 3.3.150 2022-08-22

- T4629 (bug): Raised ConfigErrors contain dict instead of only the dict key
- T4632 (bug): VLAN-aware bridge not working

### 3.3.151 2022-08-19

- T4616 (bug): openconnect: KeyError: 'local\_users'
- T4614 (feature): OpenConnect split-dns directive

### 3.3.152 2022-08-16

- T4592 (bug): macsec: can not create two interfaces using the same source-interface
- T4584 (bug): hostap: create custom package build
- T4537 (bug): MACsec not working with cipher gcm-aes-256

### 3.3.153 2022-08-15

- T4565 (bug): vlan aware bridge not working with - Kernel: T3318: update Linux Kernel to v5.4.205 #249
- T4206 (bug): Policy Based Routing with DHCP Interface Issue
- T2763 (feature): New SNMP resource request - SNMP over TCP

### 3.3.154 2022-08-14

- T4579 (bug): bridge: can not delete member interface CLI option when VLAN is enabled
- T4421 (default): Add support for floating point numbers in the numeric validator
- T4415 (bug): Include license/copyright files in the image but remove user documentation from /usr/share/doc to reduce its size
- T4313 (bug): "generate public-key-command" throws unhandled exceptions when it cannot retrieve the key
- T4082 (bug): Add op mode command to restart ldpd
- T3714 (bug): Some sysctl custom parameters disappear after reboot
- T4260 (bug): Extend vyos.configdict.node\_changed() to support recursiveness
- T3785 (default): Add unicode support to configtree backend
- T3507 (bug): Bond with mode LACP show u/u in show interfaces even if peer is not configured

### 3.3.155 2022-08-11

- T4476 (default): Next steps after installation is not communicated properly to new users

### 3.3.156 2022-08-02

- T4515 (default): Reduce telegraf binary size

### 3.3.157 2022-07-30

- T4575 (feature): vyos.util add new wrapper "rc\_cmd" to get the return code and output
- T4532 (bug): Flow-accounting IPv6 server/receiver bug

### 3.3.158 2022-07-27

- T4571 (bug): Sflow with vrf configured does not use vrf to validate agent-address IP from vrf-configured interfaces

### 3.3.159 2022-07-18

- T4228 (bug): bond: OS error thrown when two bonds use the same member
- T4534 (bug): bond: bridge: error out if member interface is assigned to a VRF instance
- T4525 (bug): Delete interface from VRF and add it to bonding error
- T4522 (feature): bond: add ability to specify mii monitor interval via CLI
- T4521 (bug): bond: ARP monitor interval is not configured despite set via CLI

### 3.3.160 2022-07-14

- T4491 (bug): Use empty string for internal name of root node of config\_tree

### 3.3.161 2022-07-13

- T1375 (feature): Add clear dhcp server lease function

### 3.3.162 2022-07-12

- T4527 (bug): Prevent to create VRF name default
- T4084 (default): Dehardcode the default login banner
- T3864 (enhancement): Add Edgecore build to VyOS 1.3 Equuleus

### 3.3.163 2022-07-09

- T4507 (feature): IPoE-server add multiplier option for shaper
- T4468 (bug): web-proxy source group cannot start with a number bug
- T4373 (feature): PPPoE-server add multiplier option for shaper

### 3.3.164 2022-07-07

- T4456 (bug): NTP client in VRF tries to bind to interfaces outside VRF, logs many messages
- T4509 (feature): Feature Request: DNS64

### 3.3.165 2022-07-06

- T4513 (bug): Webproxy monitor commands do not work

### 3.3.166 2022-07-05

- T4510 (bug): set system static-host-mapping doesn't allow IPv4 and IPv6 for same name.
- T2654 (bug): Multiple names unable to be assigned to the same static mapping
- T2683 (default): no dual stack in system static-host-mapping host-name

### 3.3.167 2022-07-01

- T4489 (bug): MPLS sysctl not persistent for tunnel interfaces

### 3.3.168 2022-06-20

- T1856 (feature): Support configuring IPSec SA bytes

### 3.3.169 2022-06-16

- T3866 (bug): Configs with DNS forwarding listening on OpenVPN interfaces or interfaces without a fixed address cannot be migrated to the new syntax

### 3.3.170 2022-06-15

- T1890 (feature): Metatask: rewrite flow-accounting to XML and Python

### 3.3.171 2022-06-09

- T2580 (feature): Support for ip pools for ippoe

### 3.3.172 2022-06-08

- T4447 (bug): DHCPv6 prefix delegation `sla-id` limited to 128
- T4350 (bug): DMVPN opennhp spokes dont work behind NAT

### 3.3.173 2022-05-30

- T4315 (feature): Telegraf - Output to prometheus

### 3.3.174 2022-05-27

- T4441 (bug): wwan: connection not possible after a change added after 1.3.1-S1 release

### 3.3.175 2022-05-26

- T4442 (feature): HTTP API add action "reset"

### 3.3.176 2022-05-25

- T2194 (default): "show firewall" garbled output

### 3.3.177 2022-05-19

- T4430 (bug): Show firewall output with visual shift default rule

### 3.3.178 2022-05-16

- T4377 (default): generate tech-support archive includes previous archives

### 3.3.179 2022-05-12

- T4100 (feature): Firewall increase maximum number of rules

### 3.3.180 2022-05-11

- T4405 (bug): DHCP client sometimes ignores `no-default-route` option of an interface

### 3.3.181 2022-05-10

- T1972 (feature): Allow setting interface name for virtual\_ipaddress in VRRP VRID

### 3.3.182 2022-05-07

- T4361 (bug): `vyos.config.exists()` does not work for nodes with multiple values
- T4354 (bug): Slave interfaces fall out from bonding during configuration change

### 3.3.183 2022-05-03

- T4395 (feature): Extend show vpn debug

### 3.3.184 2022-05-01

- T4369 (bug): OpenVPN: daemon not restarted on changes to "openvpn-option" CLI node
- T4363 (bug): salt-minion: default mine\_interval option is not set

### 3.3.185 2022-04-29

- T4388 (bug): dhcp-server: missing constraint on tftp-server-name option
- T4366 (bug): geneve: interface is removed on changes to e.g. description

### 3.3.186 2022-04-26

- T4235 (default): Add config tree diff algorithm

### 3.3.187 2022-04-19

- T4344 (bug): DHCP statistics not matching, conf-mode generates incorrect pool name with dash
- T4268 (bug): Elevated LA while using VyOS monitoring feature

### 3.3.188 2022-04-08

- T4331 (bug): IPv6 link local addresses are not configured when an interface is in a VRF
- T4339 (bug): wwan: tab-completion results in "No such file or directory" if there is no WWAN interface
- T4338 (bug): wwan: changing interface description should not trigger reconnect
- T4324 (bug): wwan: check alive script should only be run via cron if a wwan interface is configured at all

### 3.3.189 2022-04-07

- T4330 (bug): MTU settings cannot be applied when IPv6 is disabled
- T4346 (feature): Deprecate "system ipv6 disable" option to disable address family within OS kernel
- T4337 (bug): isis: IETF SPF delay algorithm can not be configured - results in vyos.frr.CommitError
- T4319 (bug): The command "set system ipv6 disable" doesn't work as expected.
- T4341 (feature): login: disable user-account prior to deletion and wait until deletion is complete
- T4336 (feature): isis: add support for MD5 authentication password on a circuit

### 3.3.190 2022-04-06

- T4308 (feature): Op-comm "Show log frr" to view specific protocol logs

### 3.3.191 2022-03-29

- T3686 (bug): Bridging OpenVPN tap with no local-address breaks

### 3.3.192 2022-03-24

- T4294 (bug): Adding a new openvpn-option does not restart the OpenVPN process
- T4230 (bug): OpenVPN server configuration deleted after reboot when using a VRRP virtual-address

### 3.3.193 2022-03-21

- T4311 (bug): CVE-2021-4034: local privilege escalation in PolKit
- T4310 (bug): CVE-2022-0778: infinite loop in OpenSSL certificate parsing

### 3.3.194 2022-03-12

- T4296 (bug): Interface config injected by Cloud-Init may interfere with VyOS native
- T4002 (default): firewall group network-group long names restriction incorrect behavior

### 3.3.195 2022-03-11

- T4297 (bug): Interface configuration saving fails for ice/iavf based interfaces because they can't change speed/duplex settings

### 3.3.196 2022-03-05

- T4259 (bug): The conntrackd daemon can be started wrongly

### 3.3.197 2022-02-28

- T4273 (bug): ssh: Upgrade from 1.2.X to 1.3.0 breaks config
- T4115 (bug): reboot in <x> not working as expected

### 3.3.198 2022-02-24

- T4267 (bug): Error - Missing required "ip key" parameter

### 3.3.199 2022-02-23

- T4264 (bug): vxlan: interface is destroyed and rebuild on description change
- T4263 (bug): vyos.util.leaf\_node\_changed() dos not honor valueLess nodes

### 3.3.200 2022-02-21

- T4120 (feature): [VXLAN] add ability to set multiple unicast-remotes

### 3.3.201 2022-02-20

- T4261 (feature): MACsec: add DHCP client support
- T4203 (bug): Reconfigure DHCP client interface causes brief outages

### 3.3.202 2022-02-19

- T4258 (bug): [DHCP-SERVER] error parameter on Failover

### 3.3.203 2022-02-17

- T4241 (bug): ocserv openconnect looks broken in recent bulds of 1.3 Equuleus
- T4255 (bug): Unexpected print of dict bridge on delete
- T4240 (bug): Cannot add wlan0 to bridge via configure
- T4154 (bug): Error add second gre tunnel with the same source interface

### 3.3.204 2022-02-16

- T4237 (bug): Conntrack-sync error - error adding listen-address command

### 3.3.205 2022-02-15

- T4201 (bug): Firewall - ICMPv6 matches not working as expected on 1.3.0
- T3006 (bug): Accel-PPP & vlan-mon config get invalid VLAN
- T3494 (bug): DHCPv6 leases traceback when PD using

### 3.3.206 2022-02-13

- T4242 (bug): ethernet speed/duplex can never be switched back to auto/auto
- T4191 (bug): Lost access to host after VRF re-creating

### 3.3.207 2022-02-11

- T3872 (feature): Add configurable telegraf monitoring service
- T4234 (bug): Show firewall partly broken in 1.3.x

### 3.3.208 2022-02-10

- T4165 (bug): Custom conntrack rules cannot be deleted

### 3.3.209 2022-02-08

- T4227 (bug): Typo in help completion of hello-time option of bridge interface

### 3.3.210 2022-02-07

- T4233 (bug): ssh: sync regex for allow/deny usernames to "system login"
- T4087 (feature): IPsec IKE-group proposals limit of 10 pieces

### 3.3.211 2022-02-05

- T4226 (bug): VRRP transition-script does not work for groups name which contains -(minus) sign

### 3.3.212 2022-02-04

- T4196 (bug): DHCP server client-prefix-length parameter results in non-functional leases

### 3.3.213 2022-02-03

- T3643 (bug): show vpn ipsec sa doesn't show tunnels in "down" state

### 3.3.214 2022-02-01

- T4198 (bug): Error shown on commit

### 3.3.215 2022-01-28

- T4184 (bug): NTP allow-clients address doesn't work it allows to use ntp server for all addresses

### 3.3.216 2022-01-24

- T4204 (feature): Update Accel-PPP to a newer revision

### 3.3.217 2022-01-17

- T3164 (bug): console-server ssh does not work with RADIUS PAM auth

### 3.3.218 2022-01-15

- T4183 (feature): IPv6 link-local address not accepted as wireguard peer
- T4110 (feature): [IPv6-SSH/DNS} enable IPv6 link local addresses as listen-address %eth0

### 3.3.219 2022-01-12

- T4168 (bug): IPsec VPN is impossible to restart when DMVPN is configured
- T4167 (bug): DMVPN apply wrong param on the first configuration
- T4152 (bug): NHRP shortcut-target holding-time does not work

### 3.3.220 2022-01-10

- T3299 (bug): Allow the web proxy service to listen on all IP addresses
- T3115 (feature): Add support for firewall on L3 VIF bridge interface

### 3.3.221 2022-01-09

- T3822 (bug): OpenVPN processes do not have permission to read key files generated with `run generate openvpn key`
- T4142 (bug): Input ifbX interfaces not displayed in op-mode
- T3914 (bug): VRRP rfc3768-compatibility doesn't work with unicast peers

### 3.3.222 2022-01-07

- T3924 (bug): VRRP stops working with VRF

### 3.3.223 2022-01-06

- T4141 (bug): Set high-availability vrrp sync-group without members error

### 3.3.224 2022-01-03

- T4065 (bug): IPSEC configuration error: connection to unix:///var/run/charonctl failed: No such file or directory
- T4052 (bug): Validator return traceback on VRRP configuration with the script path not in config dir
- T4128 (bug): keepalived: Upgrade package to add VRF support

### 3.3.225 2021-12-31

- T4081 (bug): VRRP health-check script stops working when setting up a sync group

### 3.3.226 2021-12-29

- T2922 (bug): The `vpn ipsec logging log-modes` miss the IPSec daemons state check
- T2695 (bug): Flow-accounting bug with subinterfaces
- T2400 (default): OpenVPN: dont restart server if no need
- T4086 (default): system login banner is not removed on deletion.

### 3.3.227 2021-12-28

- T3380 (bug): "show vpn ike sa" does not display IPv6 peers
- T2933 (feature): VRRP add option virtual\_ipaddress\_excluded

### 3.3.228 2021-12-27

- T2566 (bug): sstp not able to run tunnels ipv6 only
- T4093 (bug): SNMPv3 snmpd.conf generation bug
- T2764 (enhancement): Increase maximum number of NAT rules

### 3.3.229 2021-12-26

- T4104 (bug): RAID1: "add raid md0 member sda1" does not restore boot sector

### 3.3.230 2021-12-25

- T4101 (bug): commit-archive: Use of uninitialized value \$source\_address in concatenation
- T4055 (feature): Add VRF support for HTTP(S) API service

### 3.3.231 2021-12-24

- T3854 (bug): Missing op-mode commands for conntrack-sync

### 3.3.232 2021-12-23

- T4092 (bug): IKEv2 mobike commit failed with DMVPN nhrp
- T3354 (default): Convert strip-private script from Perl to Python

### 3.3.233 2021-12-22

- T3356 (feature): Script for remote file transfers

### 3.3.234 2021-12-21

- T4053 (bug): VRRP impossible to set scripts out of the /config directory
- T4013 (bug): Add pkg cloudwatch for AWS images
- T3913 (bug): VRF traffic fails after upgrade from 1.3.0-RC6 to 1.3.0-EPA1/2

### 3.3.235 2021-12-20

- T4088 (default): Fix typo in login banner

### 3.3.236 2021-12-19

- T3912 (default): Use a more informative default post-login banner

### 3.3.237 2021-12-17

- T3176 (bug): Ordering of ports on EdgeCore SAF51015I is mixed up?
- T4059 (bug): VRRP sync-group transition script does not persist after reboot

### 3.3.238 2021-12-16

- T4046 (feature): Sflow - Add Source address parameter
- T2615 (default): Provide an explicit option for server fingerprint in commit archive, and make insecure the default
- T4076 (enhancement): Allow setting CORS options in HTTP API
- T3378 (bug): commit-archive source-address broken for IPv6 addresses

### 3.3.239 2021-12-15

- T4077 (bug): `op-mode: bfd: drop "show protocols bfd" in favour of "show bfd"`
- T4073 (bug): `"show protocols bfd peer <>"` shows incorrect peer information.

### 3.3.240 2021-12-14

- T4071 (feature): Allow HTTP API to bind to unix domain socket

### 3.3.241 2021-12-12

- T4036 (bug): `VXLAN incorrect raiseError if set multicast network instead of single address`

### 3.3.242 2021-12-10

- T4068 (feature): `Python: ConfigError should insert line breaks into the error message`

### 3.3.243 2021-12-09

- T4033 (bug): `VRRP - Error security when setting scripts`
- T4064 (bug): `IP address for vif is not removed from the system when deleted in configuration`
- T4063 (bug): `VRRP log error - /usr/libexec/vyos/vyos-vrrp-conntracksync.sh - No such file or directory`
- T4060 (enhancement): `Extend configquery for use before boot configuration is complete`

### 3.3.244 2021-12-08

- T4024 (bug): `Access-lists and prefix-lists disappear when setting ldp hello-ipv4-interval`

### 3.3.245 2021-12-07

- T4041 (servicerequest): `"transition-script" doesn't work on "sync-group"`

### 3.3.246 2021-12-06

- T4012 (feature): `Add VRF support for TFTP`

### 3.3.247 2021-12-05

- T4034 (bug): "make xcp-ng-iso" still includes vyos-xe-guest-utilities
- T2076 (feature): RAID install: sfdisk change-id is deprecated in favor of --part-type
- T1126 (bug): Reusing a RAID from a BIOS install in an EFI install causes a failure to boot

### 3.3.248 2021-12-04

- T4049 (feature): support command-style output with compare command
- T4047 (bug): Wrong regex validation in XML definitions
- T4045 (bug): Unable to "format disk <new> like <old>"

### 3.3.249 2021-12-02

- T4035 (bug): Geneve interfaces aren't displayed by operational mode commands

### 3.3.250 2021-12-01

- T3695 (bug): OpenConnect reports commit success when ocserv fails to start due to SSL cert/key file issues

### 3.3.251 2021-11-30

- T3725 (feature): show configuration in json format

### 3.3.252 2021-11-29

- T2661 (bug): SSTP wrong certificates check
- T3946 (enhancement): Automatically resize the root partition if the drive has extra space

### 3.3.253 2021-11-28

- T3999 (bug): show lldp neighbor Traceback error

### 3.3.254 2021-11-26

- T4019 (bug): Smoketests for SSTP and openconnect fails

### 3.3.255 2021-11-25

- T4005 (feature): Feature Request: IPsec IKEv1 + IKEv2 for one peer

### 3.3.256 2021-11-24

- T4015 (feature): Update Accel-PPP to a newer revision
- T1083 (feature): Implement persistent/random address and port mapping options for NAT rules

### 3.3.257 2021-11-23

- T3990 (bug): WATCHFRR: crashlog and per-thread log buffering unavailable (due to files left behind in /var/tmp/frr/ after reboot)

### 3.3.258 2021-11-20

- T4004 (bug): IPsec ike-group parameters are not saved correctly (after reboot)

### 3.3.259 2021-11-19

- T4003 (bug): API for "show interfaces ethernet" does not include the interface description
- T4011 (bug): ethernet: deleting interface should place interface in admin down state

### 3.3.260 2021-11-18

- T3995 (feature): OpenVPN: do not stop/start service on configuration change
- T4008 (feature): dhcp: change client retry interval from 300 -> 60 seconds
- T3795 (bug): WWAN: issues with non connected interface / no signal

### 3.3.261 2021-11-17

- T3350 (bug): OpenVPN config file generation broken
- T3996 (bug): SNMP service error in log

### 3.3.262 2021-11-15

- T3934 (bug): Openconnect VPN broken: ocserv-worker general protection fault on client connect
- T3724 (feature): Allow setting host-name in l2tp section of accel-ppp

### 3.3.263 2021-11-14

- T3974 (bug): route-map commit fails if interface does not exist

### 3.3.264 2021-11-11

- T1349 (bug): L2TP remote-access vpn terminated and not showing as connected
- T1058 (default): hw-id is ignored when naming interfaces
- T914 (feature): Extend list\_interfaces.py to support multiple interface types
- T688 (enhancement): Move component versions used for config migration purposes into vyos-1x

### 3.3.265 2021-11-10

- T3982 (bug): DHCP server commit fails if static-mapping contains + or .

### 3.3.266 2021-11-09

- T3962 (bug): Image cannot be built without open-vm-tools
- T2088 (bug): Increased boot time from 1.2.4 -> 1.3 rolling by 100%
- T2136 (bug): XML command definition convertor doesn't disallow tag nodes with multi flag on

### 3.3.267 2021-11-07

- T2874 (feature): Add MTU and TCP-MSS discovery tool
- T3626 (bug): Configuring and disabling DHCP Server

### 3.3.268 2021-11-06

- T3971 (feature): Ability to build ISO images for XCP-NG hypervisor
- T3514 (bug): NIC flap at any interface change

### 3.3.269 2021-11-05

- T3972 (bug): Removing vif-c interface raises KeyError

### 3.3.270 2021-11-04

- T3964 (bug): SSTP: local-user static-ip CLI node accepts invalid IPv4 addresses

### 3.3.271 2021-11-03

- T3610 (bug): DHCP-Server creation for not primary IP address fails

### 3.3.272 2021-11-01

- T3846 (bug): dmvpn configuration not reapplied after "restart vpn"
- T3956 (bug): GRE tunnel - unable to move from source-interface to source-address, commit error

### 3.3.273 2021-10-31

- T3945 (feature): Add route-map for bgp aggregate-address
- T3341 (bug): Wrong behavior of the "reset vpn ipsec-peer XXX tunnel XXX" command
- T3954 (bug): FTDI cable makes VyOS sagitta latest hang, /dev/serial unpopulated, config system error
- T3943 (bug): "netflow source-ip" prevents image upgrades if IP address does not exist locally

### 3.3.274 2021-10-29

- T3942 (feature): Generate IPsec debug archive from op-mode

### 3.3.275 2021-10-28

- T3941 (bug): "show vpn ipsec sa" shows established time of parent SA not child SA's

### 3.3.276 2021-10-27

- T3944 (bug): VRRP fails over when adding new group to master

### 3.3.277 2021-10-25

- T3935 (bug): Update from rc5 to EPA2 failed

### 3.3.278 2021-10-22

- T3188 (bug): Tunnel local-ip to dhcp-interface Change Fails to Update

### 3.3.279 2021-10-21

- T3920 (bug): dhclient exit hook script 01-vyos-cleanup causes too many arguments error
- T3926 (bug): strip-private does not sanitize "cisco-authentication" from NHRP configuration
- T3925 (feature): Tunnel: dhcp-interface not implemented - use source-interface instead
- T3927 (feature): Kernel: Enable kernel support for HW offload of the TLS protocol

### 3.3.280 2021-10-20

- T3922 (bug): NHRP: delete fails
- T3918 (bug): DHCPv6 prefix delegation incorrect verify error
- T3921 (bug): tunnel: KeyError when using dhcp-interface

### 3.3.281 2021-10-19

- T3396 (bug): syslog can't be configured with an ipv6 literal destination in 1.2.x
- T690 (feature): Allow OpenVPN servers to push routes with custom metric values

### 3.3.282 2021-10-17

- T3786 (bug): GRE tunnel source address 0.0.0.0 error
- T3425 (bug): Scripts from the /config/scripts/ folder do not run on live system
- T3217 (default): Save FRR configuration on each commit
- T3076 (bug): Router reboot adds unwanted 'conntrack-sync mcast-group '225.0.0.50'' line to configuration
- T2800 (bug): Pseudo-Ethernet: source-interface must not be member of a bridge
- T3422 (bug): Dynamic DNS doesn't allow zone field with cloudflare protocol
- T3381 (bug): Change GRE tunnel failed
- T3254 (bug): Dynamic DNS status shows incorrect last update time
- T3253 (bug): rpki: multiple peers cannot be configured
- T3219 (default): Typo in openvpn server client config for IPv6 iroute

- T2100 (feature): BGP route advertisement with checks rib
- T1663 (enhancement): T1656 equuleus: buster: arm64/aarch64: ipaddrcheck does not complete testing
- T1243 (bug): BGP local-as accept wrong values
- T770 (bug): Bonded interfaces get updated with incorrect hw-id in config.
- T697 (bug): Clean up and sanitize package dependencies
- T3837 (default): OpenConnect: Fix typo in help property
- T1440 (bug): Creating two DHCPv6 shared-network-names with the same subnet is allowed, causes dhcpd to fail to start.
- T578 (feature): Support Linux Container

### 3.3.283 2021-10-16

- T3879 (bug): GPG key verification fails when upgrading from a 1.3 beta version
- T3851 (bug): Missing ospf and rip options for bridge vifs

### 3.3.284 2021-10-13

- T3904 (bug): NTP pool associations silently fail
- T3277 (feature): DNS Forwarding - reverse zones

### 3.3.285 2021-10-11

- T2607 (feature): Support for pppoe-server radius mode auth and config radius accounting port

### 3.3.286 2021-10-10

- T3750 (bug): pdns-recursor 4.4 issue with dont-query and private DNS servers
- T3885 (default): dhcpv6-pd: randomly generated DUID is not persisted
- T3899 (enhancement): Add support for hd44780 LCD displays

### 3.3.287 2021-10-09

- T3894 (bug): Tunnel Commit Failed if system does not have `eth0`

### 3.3.288 2021-10-08

- T3893 (bug): MGRE Tunnel commit crash If sit tunnel available

### 3.3.289 2021-10-04

- T3888 (bug): Incorrect warning when poweroff command executed from configure mode.
- T3890 (feature): dhcp(v6): provide op-mode commands to retrieve both server and client logfiles
- T3889 (feature): Migrate to journalctl when reading daemon logs

### 3.3.290 2021-10-03

- T3880 (bug): EFI boot shows error on display

### 3.3.291 2021-10-02

- T3882 (feature): Upgrade PowerDNs recursor to 4.5 series
- T3883 (bug): VRF - Delete vrf config on interface

### 3.3.292 2021-10-01

- T3877 (bug): VRRP always enabled rfc3768-compatibility even when not specified

### 3.3.293 2021-09-30

- T3874 (bug): D-Link Ethernet Interface not working.

### 3.3.294 2021-09-27

- T3858 (bug): Deleting OSPFv3 process yields: Unknown command: no router-id

### 3.3.295 2021-09-26

- T3860 (bug): Error on pppoe, tunnel and wireguard interfaces for IPv6 EUI64 addresses
- T3857 (feature): reboot: send wall message to all users for information
- T3867 (bug): vxlan: multicast group address is not validated
- T3859 (bug): Add "log-adjacency-changes" to ospfv3 process

### 3.3.296 2021-09-23

- T3850 (bug): Dots are no longer allowed in SSH public key names

### 3.3.297 2021-09-21

- T2602 (bug): pptp/sstp/l2tp add possibility enable or disable CCP

### 3.3.298 2021-09-19

- T3841 (feature): dhcp-server: add ping-check option to CLI
- T2738 (bug): Modifying configuration in the "interfaces" section from VRRP transition scripts causes configuration lockup and high CPU utilization
- T3842 (feature): Backport DHCP server improvements from VyOS 1.4 sagitta to 1.3 equuleus
- T3840 (feature): dns forwarding: Cache size should allow values > 10k
- T3672 (bug): DHCP-F0 with multiple subnets results in invalid/non-functioning dhcpd.conf configuration file output

### 3.3.299 2021-09-11

- T3402 (feature): Add VyOS programming library for operational level commands

### 3.3.300 2021-09-10

- T3802 (bug): Commit fails if ethernet interface doesn't support flow control
- T3819 (bug): Upgrade Salt Stack 3002.3 -> 3003 release train
- T3421 (bug): MTR/Traceroute broken in 1.3-beta
- T3820 (feature): PowerDNS recursor - update from 4.3 -> 4.4 to sync with current
- T1770 (bug): webproxy breaks commit and http access on routed client
- T915 (feature): MPLS Support

### 3.3.301 2021-09-09

- T3816 (bug): Error after entering outbound-interface command in NAT
- T3814 (bug): wireguard: commit error showing incorrect peer name from the configured name
- T3805 (bug): OpenVPN insufficient privileges for rtnetlink when closing TUN/TAP interface

### 3.3.302 2021-09-07

- T2322 (bug): CLI [op-mode] bugs. Root task
- T1894 (bug): FRR config not loaded after daemons segfault or restart
- T3807 (bug): Op Command "show interfaces wireguard" does not show the output
- T3808 (default): ipsec is mistakenly restarted after delete

### 3.3.303 2021-09-06

- T3806 (bug): Don't set link local ipv6 address if MTU less then 1280
- T3803 (default): Add source-address option to the ping CLI
- T3431 (bug): Show version all bug
- T3362 (bug): 1.3 - RC1 ifb redirect failing to commit
- T3291 (bug): Fault on setting offload RPS with single-core CPU
- T2920 (bug): Commit crash when adding the second mGRE tunnel with the same key
- T2895 (bug): VPN IPsec "leftsubnet" declared 2 times
- T2019 (bug): LLDP wrong config generation for interface 'all'

### 3.3.304 2021-09-05

- T3804 (feature): cli: Migrate and merge "system name-servers-dhcp" into "system name-server"

### 3.3.305 2021-09-04

- T3697 (bug): Impossible to delete IPsec completely
- T3619 (bug): Performance Degradation 1.2 --> 1.3 | High ksoftirqd CPU usage
- T1785 (bug): Deleting partitions on disks (Raid1) with default value 'no'

### 3.3.306 2021-09-03

- T3788 (bug): Keys are not allowed with ipip and sit tunnels
- T3683 (bug): VXLAN not accept ipv6 and source-interface options and mtu bug
- T3634 (feature): Add op command option for ping for do not fragment bit to be set

### 3.3.307 2021-09-02

- T3792 (bug): login: A hyphen present in a username from "system login user" is replaced by an underscore
- T3790 (bug): Does not possible to configure PPTP static ip-address to users

### 3.3.308 2021-09-01

- T2434 (bug): Duplicate Address Detection Breaks Interfaces

### 3.3.309 2021-08-31

- T3789 (feature): Add custom validator for base64 encoded CLI data
- T3782 (default): Ingress Shaping with IFB No Longer Functional with 1.3

### 3.3.310 2021-08-30

- T3777 (bug): adding IPv6 EUI64 address fails commit in 1.3.0-rc6
- T3768 (default): Remove early syntaxVersion implementation
- T2558 (feature): Add some CPU information to `show version` + fix broken hypervisor detection
- T2430 (default): cannot delete specific route static next-hop
- T1350 (bug): VRRP transition script will be executed once only
- T2941 (default): Using a non-ASCII character in the description field causes UnicodeDecodeError in configsource.py
- T3787 (bug): Remove deprecated UDP fragmentation offloading option
- T3677 (feature): "sipcalc" not included in 1.3

### 3.3.311 2021-08-29

- T3708 (bug): isisd and gre-bridge commit error
- T3783 (bug): "set protocols isis spf-delay-ietf" is not working
- T2750 (default): Use m4 as a template processor

### 3.3.312 2021-08-27

- T3182 (bug): Main blocker Task for FRR 7.4/7.5 series update
- T2108 (default): Use minisign/signify instead of GPG for release signing

### 3.3.313 2021-08-26

- T3781 (bug): Revert the NAT implementation in 1.3 back to iptables
- T3776 (default): Rename FRR daemon restart op-mode commands
- T3779 (feature): Backport all 1.4 IS-IS features and configuration to 1.3 except VRF

### 3.3.314 2021-08-25

- T3773 (bug): Delete the "show system integrity" command (to prepare for a re-implementation)
- T1514 (default): Add ability to restart frr processes

### 3.3.315 2021-08-24

- T3772 (bug): VRRP virtual interfaces are not shown in show interfaces

### 3.3.316 2021-08-23

- T2555 (bug): XML op-mode generation scripts silently discard XML nodes

### 3.3.317 2021-08-21

- T3682 (bug): Remove running dhclient from ether-resume.py

### 3.3.318 2021-08-20

- T1950 (default): Store VyOS configuration syntax version data in JSON file

### 3.3.319 2021-08-19

- T2759 (bug): validate-value prints error messages from validators that fail even if overall validation succeeds
- T3234 (bug): multi\_to\_list fails in certain cases, with root cause an element redundancy in XML interface-definitions
- T3732 (feature): override-default helper should support adding defaultValues to default less nodes
- T1962 (default): Add syntax version to schema

### 3.3.320 2021-08-17

- T2525 (bug): OSPFv3 missing route map, not establishing
- T508 (bug): ISC DHCP incorrect UDP checksum generation
- T1643 (bug): Deleting all firewall zones failed and locked out box
- T1550 (bug): Add support for Large BGP Community show commands

### 3.3.321 2021-08-16

- T3738 (default): openvpn fails if server and authentication are configured
- T1594 (bug): l2tpv3 error on IPv6 local-ip

### 3.3.322 2021-08-15

- T3756 (default): VyOS generates invalid QR code for wireguard clients

### 3.3.323 2021-08-14

- T3745 (feature): op-mode IPsec show vpn ipse sa sorting
- T521 (bug): Network services may fail if vyatta-router.service startup takes longer than a few seconds

### 3.3.324 2021-08-13

- T3740 (bug): HTTPs API breaks when the address is IPv6

### 3.3.325 2021-08-12

- T3731 (bug): verify\_accel\_ppp\_base\_service return wrong config error for SSP
- T3405 (feature): PPPoE server unit-cache
- T2432 (default): dhcpcd: Can't create new lease file: Permission denied
- T3746 (feature): Inform users logging into the system about a pending reboot
- T3744 (default): Dns forwarding statistics formatting missing a new line

### 3.3.326 2021-08-10

- T3730 (bug): op-mode conntrack-sync miss some functions

### 3.3.327 2021-08-09

- T1501 (bug): VPN Commit Errors

### 3.3.328 2021-08-08

- T2027 (bug): `get_config_dict` is failing when the configuration section is empty/missing
- T169 (feature): Image install should put correct serial console device in created GRUB menu entry

### 3.3.329 2021-08-07

- T548 (feature): BGP IPv6 multipath support

### 3.3.330 2021-08-06

- T1153 (bug): VyOS 1.2.0RC10, RAID-1, fresh install, unable to save config

### 3.3.331 2021-08-05

- T696 (feature): Rewrite conntrack sync to XML

### 3.3.332 2021-08-04

- T3704 (feature): Add ability to interact with Areca RAID adapters
- T320 (default): OSPF does not redistribute connected routes associated with virtual tunnel interfaces

### 3.3.333 2021-08-02

- T2623 (bug): Creating sit tunnel fails with "Can not set "local" for tunnel sit tun1 at tunnel creation"
- T2161 (default): `snmpd` cannot start if `ipv6` disabled
- T3601 (default): Error in ssh keys for vmware cloud-init if ssh keys is left empty.

### 3.3.334 2021-08-01

- T3707 (bug): Ping incorrect ip host checks

### 3.3.335 2021-07-31

- [T3716](#) (feature): Linux kernel parameters `ignore_routes_with_link_down`- ignore disconnected routing connections
- [T1626](#) (bug): BGP exchanges prefixes without specified address-family

### 3.3.336 2021-07-30

- [T1176](#) (default): FRR - BGP replicating routes
- [T1123](#) (bug): Inconsistency in `community-list` naming validation

### 3.3.337 2021-07-29

- [T2931](#) (bug): Unicode decode error causes `vyos.configd` service to restart
- [T2727](#) (bug): Add a dotted decimal value validator
- [T2328](#) (default): `dhcpv6` server not starting (disable check reversed?)
- [T1758](#) (default): Switch `vyos.config` to `libvyosconfig`
- [T954](#) (bug): Using the `10.255.255.0/24` subnet on other interfaces breaks L2TP/IPSec

### 3.3.338 2021-07-23

- [T3699](#) (bug): `login: verify` selected "system login user" name is not already used by the base system.

### 3.3.339 2021-07-21

- [T3689](#) (bug): static ipv6 route doesn't deleted in some cases
- [T3685](#) (feature): IPv6 PBR doesn't allow setting of an egress interface

### 3.3.340 2021-07-20

- [T3691](#) (bug): GRE-TAP: key is not applied when interface is created

### 3.3.341 2021-07-13

- [T3679](#) (default): Point the unexpected exception message link to the new rolling release location

### 3.3.342 2021-07-11

- T3665 (bug): Missing VRF support for VxLAN but already documented

### 3.3.343 2021-07-06

- T3660 (feature): Conntrack-Sync configuration command to specify destination udp port for peer

### 3.3.344 2021-07-01

- T3658 (feature): Add support for dhcpdv6 fixed-prefix6

### 3.3.345 2021-06-29

- T3593 (bug): PPPoE server called-sid format does not work

### 3.3.346 2021-06-25

- T3650 (bug): OpenVPN: Upgrade package to 2.5.1 before releasing VyOS 1.3.0
- T3649 (feature): Add bonding additional hash-policy

### 3.3.347 2021-06-24

- T2722 (bug): get\_config\_dict() and key\_mangling=(-, '\_') will alter CLI data for tagNodes

### 3.3.348 2021-06-22

- T3629 (bug): IPoE server shifting address in the range

### 3.3.349 2021-06-20

- T3637 (bug): vrf: bind-to-all didn't work properly

### 3.3.350 2021-06-19

- T3633 (feature): Add LRO offload for interface ethernet

### 3.3.351 2021-06-17

- T3631 (feature): route-map: migrate "set extcommunity-rt" and "set extcommunity-soo" to "set extcommunity rt|soo" to match FRR syntax

### 3.3.352 2021-06-16

- T2425 (feature): Rewrite all policy zebra filters to XML/Python style
- T3630 (feature): op-mode: add "show version kernel" command

### 3.3.353 2021-06-13

- T3620 (feature): Rename WWAN interface from wirelessmodem to wwan to use QMI interface
- T3622 (feature): WWAN: add support for APN authentication
- T3621 (bug): PPPoE interface does not validate if password is supplied when username is set

### 3.3.354 2021-06-10

- T3250 (bug): PPPoE server: wrong local usernames
- T3138 (bug): ddclient improperly updated when apply rfc2136 config
- T2645 (default): Editing route-map action requires adding a new rule

### 3.3.355 2021-06-09

- T3602 (bug): Renaming BGP Peer Groups Leaves Router Broken
- T2916 (bug): A state of VTI interface in a configuration does not being processing properly

### 3.3.356 2021-06-08

- T3605 (default): Allow to set prefer-global for ipv6-next-hop
- T3607 (feature): [route-map] set ipv6 next-hop prefer-global

### 3.3.357 2021-06-07

- T3581 (bug): Incomplete command `show ipv6 ospfv3 linkstate`
- T3516 (bug): FRR 7.5 adds a second route when you attempt to change a static route distance instead of overwriting the old route
- T3461 (bug): OpenConnect Server redundancy check
- T3455 (bug): system users can not be added in "edit"

### 3.3.358 2021-06-04

- T3592 (feature): Set default TTL 64 for tunnels

### 3.3.359 2021-06-01

- T406 (bug): VPN configuration error: IPv6 over IPv4 IPsec is not supported when using IPv6 ONLY tunnel.

### 3.3.360 2021-05-30

- T1866 (bug): Commit archive over SFTP doesn't work with non-standard ports
- T3589 (feature): op-mode: support clearing out logfiles from CLI
- T3508 (bug): Check if there's enough drive space for an upgrade before downloading an image
- T1506 (enhancement): commit-archive scp/sftp public key authentication

### 3.3.361 2021-05-29

- T3135 (bug): BFD configurations fail to be applied
- T3103 (default): Rewrite parts of vyos\frr.py for readability, logging and to fix multiline regex "bugs"
- T2739 (default): vyos-utils is not compiled with a Jenkins pipeline.
- T2451 (bug): Cannot use !tcp or !tcp\_udp while adding firewall rule
- T2436 (default): equuleus: Testing: vyos-1x: syntax checking Python scripts in PR
- T2184 (bug): OpenVPN op\_mode tools broken
- T1944 (bug): FRR: Invalid route in BGP causes update storm, memory leak, and failure of Zebra

### 3.3.362 2021-05-28

- T1579 (feature): Rewrite all interface types in new XML/Python style

### 3.3.363 2021-05-27

- T2629 (bug): VXLAN interfaces don't actually allow you to configure most settings
- T2617 (feature): Rewrite vyatta-op-quagga "show" to XML
- T2512 (feature): vyatta-op-quagga [show ip] to XML format
- T1905 (default): Update to Keepalived 2.0.19
- T2669 (bug): DHCP-server overlapping ranges.

### 3.3.364 2021-05-26

- T3558 (default): autocomplete options for dhcp-interface is not showing for the static route command
- T3540 (bug): Keepalived memory utilisation issue when constantly getting its state in JSON format
- T2807 (feature): IPv6 Link-Local Address - Automatically generation/configuration on GRE Interfaces

### 3.3.365 2021-05-24

- T3575 (bug): pseudo-ethernet: must check source-interface MTU
- T3571 (bug): Broken Show Tab Complete
- T3576 (bug): ISIS does not support IPV6

### 3.3.366 2021-05-23

- T3570 (default): Prevent setting of a larger MTU on child interfaces
- T3572 (feature): Basic Drive Diagnostic Tools

### 3.3.367 2021-05-20

- T3554 (feature): Add area-type stub for ospfv3

### 3.3.368 2021-05-19

- T3562 (feature): Update Accel-PPP to a newer revision
- T3559 (feature): Add restart op-command for OpenConnect Server

### 3.3.369 2021-05-18

- T3525 (default): VMWare resume script syntax errors
- T2462 (default): LLDP op-mode exception: IndexError: list index out of range

### 3.3.370 2021-05-15

- T3549 (bug): DHCPv6 "service dhcpv6-server global-parameters name-server" is not correctly exported to dhcpdv6.conf when multiple name-server entries are present
- T3532 (bug): Not possible to change ethertype after interface creation
- T3550 (bug): Router-advert completion typo
- T3547 (feature): conntrackd: remove deprecated config options
- T3535 (feature): Rewrite vyatta-conntrack-sync in new XML and Python flavor
- T2049 (feature): Update strongSwan cipher suites list for IPSec settings

### 3.3.371 2021-05-14

- T3346 (bug): nat 4-to-5 migration script fails when a 'source' or 'destination' node exists but there are no rules
- T3248 (default): Deal with VRRP mode-force command that exists in 1.2 but not in 1.3
- T3426 (default): add support for script arguments to vyos-configd

### 3.3.372 2021-05-13

- T3544 (feature): DHCP server should validate configuration before applying it
- T3543 (feature): Support for setting lacp\_rate on LACP bonded interfaces

### 3.3.373 2021-05-12

- T3302 (default): Make vyos-configd relay stdout from scripts to the user's console

### 3.3.374 2021-05-11

- T3526 (bug): Smoketest policy fail in CI

### 3.3.375 2021-05-10

- T3528 (bug): Frr 7.5.1 uses 'seq' for community-lists

### 3.3.376 2021-05-08

- T3517 (bug): FRR 7.5 bfd behavior for 1.3

### 3.3.377 2021-05-07

- T1171 (bug): 1.2.0 epa2 - IPsec VPN initiation

### 3.3.378 2021-05-06

- T3519 (bug): Cannot add / assign L2TPv3 to vrf

### 3.3.379 2021-05-01

- T3379 (feature): Add global-parameters name-server for dhcpv6-server
- T3491 (default): Change Kernel HZ to 1000

### 3.3.380 2021-04-30

- T3170 (default): Add a sanity check for empty node.def files

### 3.3.381 2021-04-29

- T3502 (bug): "system ip multipath layer4-hashing" doesn't work
- T3029 (bug): Generated NGINX configuration is wrong for the redirection (http -> https)
- T3156 (feature): Add op and additional conf commands for ISIS
- T2012 (feature): Global PBR
- T1314 (feature): Allow BGP on unnumbered interfaces

### 3.3.382 2021-04-27

- T2946 (bug): Calling 'stty\_size' causes show interfaces API to fail

### 3.3.383 2021-04-25

- T3468 (bug): Tunnel interfaces aren't suggested as being available for bridging (regression)
- T1802 (feature): Wireguard QR code in cli for mobile devices

### 3.3.384 2021-04-23

- T3290 (bug): Disabling GRE conntrack module fails

### 3.3.385 2021-04-18

- T3481 (default): Exclude tag node values from key mangling
- T3475 (bug): XML dictionary cache unable to process syntaxVersion elements

### 3.3.386 2021-04-15

- T3386 (bug): PPPoE-server don't start with local authentication

### 3.3.387 2021-04-14

- T3055 (bug): op-mode incorrect naming for ipsec policy-based tunnels

### 3.3.388 2021-04-12

- T3454 (enhancement): dhclient reject option

### 3.3.389 2021-04-05

- T1612 (default): dhcp-server time-offset fails to validate
- T3438 (bug): VRF: removing vif which belongs to a vrf, will delete the entire vrf from the operating system
- T3418 (bug): BGP: system wide known interface can not be used as neighbor

### 3.3.390 2021-04-04

- T3457 (feature): Output the "monitor log" command in a colorful way

### 3.3.391 2021-03-31

- T3445 (bug): vyos-1x build include not all nodes

### 3.3.392 2021-03-25

- T2639 (feature): sort output of show vpn ipsec sa

### 3.3.393 2021-03-22

- T3284 (bug): merge/load fail silently if unable to resolve host

### 3.3.394 2021-03-21

- T3416 (bug): NTP: when running inside a VRF op-mode commands do not work

### 3.3.395 2021-03-20

- T3392 (bug): vrrp over dhcp default route bug (unexpected vrf)
- T3373 (feature): Upgrade to SaltStack version 3002.5
- T3329 (default): "system conntrack ignore" rules can no longer be created due to an iptables syntax change
- T3300 (feature): Add DHCP default route distance
- T3306 (feature): Extend set route-map aggregator as to 4 Bytes

### 3.3.396 2021-03-18

- [T3411](#) (default): Extend the `redirect_stdout` context manager in `vyos-configd` to `redirect stdout` from subprocesses
- [T3271](#) (bug): `qemu-kvm grub` issue

### 3.3.397 2021-03-17

- [T3413](#) (bug): Configuring invalid IPv6 EUI64 address results in "OSError: illegal IP address string passed to `inet_pton`"

### 3.3.398 2021-03-14

- [T2271](#) (feature): OSPF: add per VRF instance support
- [T175](#) (feature): Add source route option to VTI interfaces

### 3.3.399 2021-03-13

- [T3406](#) (bug): `tunnel: interface` no longer supports specifying `encaplimit none` - or migrator is missing
- [T3407](#) (bug): `console-server`: do not allow to spawn a `console-server` session on serial port used by "system console"

### 3.3.400 2021-03-11

- [T3399](#) (bug): RPKI: dashes in hostnames are replaced with underscores when rendering the FRR config
- [T3305](#) (bug): Ingress `qdisc` does not work anymore in 1.3-rolling-202101 snapshot
- [T2927](#) (bug): `isc-dhcpd` release and expiry events never execute
- [T899](#) (bug): Tunnels cannot be moved from one bridge to another
- [T786](#) (feature): new style `xml` and `conf-mode` scripts: possibility to add `tagNode` value as parameter to `conf-script`

### 3.3.401 2021-03-09

- [T3382](#) (bug): Error creating Console Server

### 3.3.402 2021-03-08

- T3387 (bug): Command "Monitor vpn ipsec" is not working

### 3.3.403 2021-03-07

- T3319 (bug): VXLAN uses ttl 1 (auto) by default
- T3391 (feature): Add CLI support for specifying maximum-paths per address family ipv4 unicast and ipv6 unicast
- T3211 (feature): ability to redistribute ISIS into other routing protocols

### 3.3.404 2021-03-05

- T2659 (feature): Add fastnetmon (DDoS detection) support

### 3.3.405 2021-03-04

- T2861 (bug): route-map "set community additive" not working correctly

### 3.3.406 2021-03-03

- T2966 (feature): tunnel: add new encapsulation types ip6tnl and ip6gretap

### 3.3.407 2021-03-01

- T3342 (bug): On xen-netback interfaces must set "scattergather" offload before MTU>1500

### 3.3.408 2021-02-28

- T3370 (bug): dhcp: Invalid domain name "private"
- T3369 (feature): VXLAN: add IPv6 underlay support

### 3.3.409 2021-02-27

- T2291 (bug): Bad hostnames in /etc/hosts with static-mapping in dhcp server config
- T3364 (feature): tunnel: cleanup/rename CLI nodes
- T3368 (feature): macsec: add support for gcm-aes-256 cipher
- T3366 (bug): tunnel: can not change local / remote ip address for gre-bridge tunnel
- T3173 (feature): Need 'nopmtudisc' option for tunnel interface

### 3.3.410 2021-02-26

- T3357 (default): HTTP-API redirect from http correct https port

### 3.3.411 2021-02-24

- T3303 (feature): Change welcome message on boot

### 3.3.412 2021-02-21

- T3163 (feature): ethernet ring-buffer can be set with an invalid value

### 3.3.413 2021-02-19

- T3326 (bug): OSPFv3: Cannot add L2TPv3 interface

### 3.3.414 2021-02-18

- T3259 (default): many dn timer rules makes the vyos http api crash, even showConfig op timeouts

### 3.3.415 2021-02-17

- T3047 (bug): OSPF : virtual-link and passive-interface default parameters does not work together
- T3312 (feature): SolarFlare NICs support

### 3.3.416 2021-02-16

- T3318 (feature): Update Linux Kernel to v5.4.208 / 5.10.142

### 3.3.417 2021-02-14

- T2152 (bug): ddclient has bug which prevents use\_web from being used
- T3308 (feature): BGP: add graceful shutdown support

### 3.3.418 2021-02-13

- T3028 (feature): Create a default user when metadata is not available (for Cloud-init builds)
- T2867 (feature): Cleanup DataSourceOVF.py in the Cloud-init
- T2726 (feature): Allow to use all supported SSH key types in Cloud-init
- T2403 (feature): Full support for networking config in Cloud-init
- T2387 (feature): Create XML scheme for [conf\_mode] BGP

- [T2174](#) (feature): Rewrite protocol BGP to new XML/Python style
- [T1987](#) (bug): A default route can be deleted by dhclient-script in some cases
- [T723](#) (feature): Add support for first boot or installation time saved config modification
- [T1775](#) (bug): Cloud-init not running userdata runcmd
- [T1389](#) (feature): Add support for NoCloud cloud-init datasources
- [T1315](#) (feature): Allow BGP to use address-family l2vpn evpn

### 3.3.419 2021-02-11

- [T2638](#) (default): FRR: New framework for configuring FRR

### 3.3.420 2021-02-08

- [T3295](#) (feature): Update Linux Kernel to v5.4.96 / 5.10.14

### 3.3.421 2021-02-07

- [T3293](#) (bug): RPKI migration script errors out after CLI rewrite

### 3.3.422 2021-02-06

- [T3285](#) (feature): Schedule reboots through systemd-shutdown instead of atd
- [T661](#) (feature): Show a warning if the router is going to reboot soon (due to "commit-confirm" command)

### 3.3.423 2021-02-05

- [T2450](#) (feature): Rewrite "protocols vrf" tree in XML and Python
- [T208](#) (feature): Ability to ignore default-route from dhcpd per interface

### 3.3.424 2021-02-03

- [T3239](#) (default): XML: override 'defaultValue' for mtu of certain interfaces; remove workarounds
- [T2910](#) (feature): XML: generator should support override of variables
- [T2873](#) (bug): "show nat destination translation address" doesn't filter at all

### 3.3.425 2021-02-02

- T3018 (bug): Unclear behaviour when configuring vif and vif-s interfaces
- T3255 (default): Rewrite protocol RPKI to new XML/Python style

### 3.3.426 2021-02-01

- T3268 (feature): Add VRF support to VIF-S interfaces
- T3274 (default): ask\_yes\_no() doesn't handle EOFError

### 3.3.427 2021-01-31

- T3276 (feature): Update Linux Kernel to v5.4.94 / 5.10.12

### 3.3.428 2021-01-30

- T3269 (bug): VIF-C interfaces don't verify configuration
- T3240 (feature): Support per-interface DHCPv6 DUIDs
- T3273 (default): PPPoE static default-routes deleted on interface down when not added by interface up

### 3.3.429 2021-01-29

- T3262 (bug): DHCPv6 client runs when dhcpv6-options is configured without requesting an address or PD
- T3261 (bug): Does not possible to disable pppoe client interface.

### 3.3.430 2021-01-27

- T3257 (feature): tcpdump supporting complete protocol
- T3110 (bug): Broken pipe in show interfaces
- T651 (enhancement): Split CI'ed, VyOS-specific packages and other packages into separate repos
- T597 (enhancement): Code testing on sonarcloud.com
- T516 (default): Make Python / XML code development more testable
- T625 (default): Lack of IKEv1 lifetime negotiation
- T613 (bug): Missing linux-kbuild
- T505 (bug): Hostapd cannot log

### 3.3.431 2021-01-26

- T3251 (bug): PPPoE client trying to authorize with the wrong username
- T2859 (bug): show nat source translation - Errors out

### 3.3.432 2021-01-25

- T3249 (feature): Support operation mode forwarding table output

### 3.3.433 2021-01-24

- T3230 (bug): RPKI can't be deleted
- T3243 (feature): Update Linux Kernel to v5.4.92 / 5.10.10

### 3.3.434 2021-01-18

- T2761 (feature): Extend "show vrrp" op-mode command with router priority
- T2679 (feature): VRRP with BFD Failure Detection
- T3212 (bug): SSH: configuration directory is not always created on boot
- T3231 (bug): "system option ctrl-alt-delete" has no effect

### 3.3.435 2021-01-17

- T3222 (bug): Typo in BGP dampening description
- T2944 (bug): NTP by default listen on any address/interface
- T3226 (bug): Repair bridge smoke test damage
- T2442 (enhancement): Move application of STP settings for bridge members from interfaces-bridge.py to Interface.add\_to\_bridge()
- T3281 (bug): OpenVPN: openvpn-option parsed/rendered improperly

### 3.3.436 2021-01-16

- T3215 (bug): Operational command "show ipv6 route" is broken
- T3172 (bug): Builds sometime after 2020-12-17 have broken routing after reboot
- T3157 (bug): salt-minion fails to start due to permission error accessing /root/.salt/minion.log
- T3167 (default): Recurring bugs in Intel NIC drivers
- T3151 (default): Decide on the final list of packages for 1.3
- T3137 (feature): Let VLAN aware bridge approach the behavior of professional equipment
- T3223 (feature): Update Linux Kernel to v5.4.89 / 5.10.7

### 3.3.437 2021-01-15

- T3210 (feature): ISIS three-way-handshake
- T3184 (feature): Add correct descriptions for BGP neighbors
- T2850 (feature): Add BGP template for FRR

### 3.3.438 2021-01-14

- T3218 (feature): Replace Intel out-of-tree drivers with Linux Kernel stock drivers.

### 3.3.439 2021-01-13

- T3186 (bug): NAT: Commit failed when applying negated(!) addresses

### 3.3.440 2021-01-12

- T3205 (bug): Does not possible to configure tunnel mode gre-bridge

### 3.3.441 2021-01-11

- T3208 (bug): Does not possible to change user password
- T3198 (bug): OSPF database filtering issue
- T3206 (bug): Unable to delete destination NAT rule
- T3193 (bug): DHCPv6 PD verification issues
- T3201 (bug): Operational command "show log all" is not working for RADIUS users

### 3.3.442 2021-01-10

- T3178 (feature): Migrate vyatta-op-quagga to vyos-1x

### 3.3.443 2021-01-09

- T2467 (bug): Restarting flow accounting fails with systemd error
- T3199 (feature): Update Linux Kernel to v5.4.88 / 5.10.6

### 3.3.444 2021-01-07

- T3192 (feature): login: radius: add support for IPv6 RADIUS servers

### 3.3.445 2021-01-05

- T3169 (enhancement): Reimplement smoke test of span (mirror)
- T3161 (default): Consider removing ConfigLoad.pm
- T1398 (default): Remove vyatta-config-migrate package
- T805 (enhancement): Drop config compatibility with Vyatta Core older than 6.5

### 3.3.446 2021-01-04

- T3185 (bug): [conf-mode] Wrong CompletionHelp for Tunnel local-ip
- T2601 (bug): pppoe-server: Cannot disable CCP

### 3.3.447 2021-01-03

- T3180 (bug): DHCP server raises NameError

### 3.3.448 2021-01-02

- T2321 (feature): VRF support for SSH, NTP, SNMP service
- T3177 (bug): Rolling Release no longer reports VMware UUID

### 3.3.449 2021-01-01

- T3171 (feature): Add CLI option to enable RPS (Receive Packet Steering)

### 3.3.450 2020-12-31

- T3162 (bug): Wrong PPPoE server pado-delay parameter added to config
- T3160 (bug): PPPoE server called-sid option defined in wrong section
- T3168 (feature): Update Linux Kernel to v5.4.86

### 3.3.451 2020-12-29

- T3082 (bug): multi\_to\_list must distinguish between values and defaults
- T1466 (feature): Add EAPOL login support

### 3.3.452 2020-12-28

- T1732 (feature): Removing vyatta-webproxy module
- T2666 (feature): Packet Processing with eBPF and XDP
- T2581 (default): webproxy: implement proxy chaining
- T563 (feature): webproxy: migrate 'service webproxy' to get\_config\_dict()

### 3.3.453 2020-12-27

- T3150 (bug): When configuring QoS, the setting procedure of port mirroring is wrong

### 3.3.454 2020-12-23

- T3143 (bug): OpenVPN server: Push route config format is wrong
- T3146 (feature): Upgrade FRR from 7.4 -> 7.5 version incl. new libyang
- T3145 (feature): Update Linux Kernel to v5.4.85
- T3147 (feature): Upgrade to SaltStack version 3002.2

### 3.3.455 2020-12-22

- T3142 (bug): OpenVPN op-command completion fails due to missing status file
- T2940 (feature): Update FRR to 7.4
- T2573 (bug): BFD op-mode commands are broken
- T2495 (feature): Add xml for ISIS [conf\_mode]
- T1316 (feature): Support for IS-IS

### 3.3.456 2020-12-21

- T2619 (bug): Bug: Changes in NAT or ZONES from 1.2 to 1.3

### 3.3.457 2020-12-20

- T3131 (bug): Typo in ipsec preshared-secret help
- T3134 (bug): DHCPv6 DUID configuration node missing
- T3140 (feature): Relax "ethernet offload-options" CLI definition
- T3132 (feature): Enable egress flow accounting

### 3.3.458 2020-12-17

- T2810 (default): Docs for vpn anyconnect-server
- T2036 (default): Open Connect VPN Server () support

### 3.3.459 2020-12-14

- T3128 (bug): pppoe smoke test failed
- T3129 (feature): Update Linux Kernel to v5.4.83
- T3089 (feature): Migrate port mirroring to vyos-lx and support two-way traffic mirroring
- T3130 (feature): Replace vyos-netplug with upstream debian version

### 3.3.460 2020-12-13

- T3114 (bug): When the bridge member is a non-ethernet interface, setting VLAN-aware bridge parameters fails

### 3.3.461 2020-12-11

- T3123 (bug): Configuration of vti interface impossible

### 3.3.462 2020-12-10

- T3117 (bug): OpenVPN config migration errors upgrading from 1.3-rolling-202010280217 to 1.3-rolling-202012060217

### 3.3.463 2020-12-09

- T3122 (feature): Update Linux Kernel to v4.19.162
- T3121 (bug): get\_config\_dict() and key\_mangling('-', '\_') Broke PowerDNS dns\_forwarding config file

### 3.3.464 2020-12-08

- T2562 (bug): VyOS can't be used as a DHCP server for a DHCP relay

### 3.3.465 2020-12-07

- T3120 (bug): Python error when deleting nat rule
- T3119 (feature): migrate "system ip" to get\_config\_dict() and provide smoketest

### 3.3.466 2020-12-05

- T2744 (bug): igmp-proxy issue: Address already in use

### 3.3.467 2020-12-04

- T3108 (bug): Section config overlapped match with FRRConfig
- T3112 (feature): PPPoE IPv6: remove "enable" node
- T3100 (feature): Migrate DHCP/DHCPv6 server to get\_config\_dict()

### 3.3.468 2020-12-03

- T3105 (bug): static-host-mapping writing in one line
- T3107 (feature): Update Linux Kernel to v4.19.161
- T3104 (bug): LLDP Traceback error

### 3.3.469 2020-12-01

- T3102 (bug): Destination NAT fails to commit
- T2713 (bug): VyOS must not change permissions on files in /config/auth

### 3.3.470 2020-11-30

- T3091 (feature): Add "tag" for static route
- T1207 (feature): DMVPN behind NAT

### 3.3.471 2020-11-29

- T3095 (feature): Migrate dhcp-relay and dhcpv6-relay to `get_config_dict()`

### 3.3.472 2020-11-28

- T2890 (bug): NAT error adding translation address range
- T2868 (bug): Tcp-mss option in policy calls kernel-panic
- T3092 (feature): nat: migrate to `get_config_dict()`

### 3.3.473 2020-11-27

- T2715 (feature): Duplicate address detection option supporting ARP
- T2714 (feature): A collection of utilities supporting IPv6 or ipv4
- T3088 (feature): Migrate IGMP-Proxy over to `get_config_dict()` and add smoketests

### 3.3.474 2020-11-24

- T3087 (feature): Update Linux Kernel to v4.19.160

### 3.3.475 2020-11-23

- T2177 (default): Commit fails on adding disabled interface to bridge
- T3066 (bug): reboot in - Invalid time
- T2802 (bug): Tunnel interface does not apply EUI-64 IPv6 Address
- T2359 (bug): Adding IPIP6 tun interface to bridge [conf\_mode] errors
- T2357 (bug): GRE-bridge conf\_mode errors
- T2259 (feature): Support for bind vif-c interfaces into VRFs
- T2205 (bug): "set interface ethernet" fails on Hyper-V
- T2182 (bug): Failure to commit an IPv6 address on a tunnel interface
- T2155 (bug): Cannot set anything on Intel 82599ES 10-Gigabit SFI/SFP+
- T2153 (bug): traceroute circular reference
- T3081 (bug): `get_config_dict()` does not honor whitespaces in the CLI values field
- T3080 (bug): OpenVPN failing silently for a number of reasons in rolling post Nov/02
- T3074 (bug): OpenVPN site-to-site creates wrong peer address
- T2542 (bug): OpenVPN client tap interfaces not coming up
- T3084 (bug): wifi: TypeError on "show interfaces wireless info"

### 3.3.476 2020-11-21

- T3079 (bug): Fix the problem that VLAN 1 will be deleted in VLAN-aware bridge
- T3060 (bug): OpenVPN virtual interface not coming up after upgrade

### 3.3.477 2020-11-20

- T3078 (feature): CLI cleanup: rename "system options" -> "system option"
- T2997 (feature): DHCP: disallow/do-not-request certain options when requesting IP address from server
- T3077 (feature): WireGuard: automatically create link-local IPv6 addresses
- T2550 (default): OpenVPN: IPv4 not working in client mode
- T3072 (feature): Migrate tunnel interfaces to new get\_config\_dict() approach
- T3065 (feature): Add "interfaces wirelessmodem" IPv6 support
- T3048 (feature): Drop static smp-affinity for a more dynamic way using tuned

### 3.3.478 2020-11-19

- T3067 (bug): Wireless interface can no longer be added to the bridge after bridge VLAN support
- T3075 (feature): Update Linux Kernel to v4.19.158

### 3.3.479 2020-11-16

- T3003 (enhancement): Extend smoketest framework to allow loading an arbitrary config file

### 3.3.480 2020-11-15

- T3069 (bug): OpenVPN routed networks not available
- T3038 (feature): Supporting AZERTY keyboards
- T2993 (bug): op-mode: lldp: show lldp neighbors - AttributeError: 'str' object has no attribute 'items'

### 3.3.481 2020-11-14

- T3041 (bug): Intel QAT: vyos-1.3-rolling-202011020217-amd64 kernel panic during configure

### 3.3.482 2020-11-13

- T3063 (feature): Add support for Huawei LTE Module ME909s-120
- T3059 (bug): L2TPv3 interface: Enforced to shutdown but no command to enable interface permanently

### 3.3.483 2020-11-12

- T3064 (feature): Update Linux Kernel to v4.19.157

### 3.3.484 2020-11-10

- T2103 (bug): Abnormal interface names if VIF present

### 3.3.485 2020-11-08

- T3050 (bug): Broken address/subnet validation on NAT configuration

### 3.3.486 2020-11-07

- T2914 (bug): OpenVPN: Fix for IPv4 remote-host hostname in client mode:
- T2653 (feature): "set interfaces" Python handler code improvements - next iteration
- T311 (feature): DHCP: set client-hostname via CLI

### 3.3.487 2020-11-06

- T3051 (bug): OpenVPN: multiple client routes do not work in server mode
- T3046 (bug): openvpn directory is not auto-created
- T3052 (feature): Update Linux firmware files to 20201022 version
- T2731 (bug): "show interfaces" returns invalid state when link is down

### 3.3.488 2020-11-05

- T3049 (feature): Update Linux Kernel to v4.19.155
- T2994 (feature): Migrate OpenVPN interfaces to get\_config\_dict() syntax

### 3.3.489 2020-11-03

- T3043 (feature): Wireless: Refactor CLI
- T3034 (feature): Add WiFi WPA 3 support
- T2967 (bug): Duplicate IPv6 BFD peers created
- T2483 (bug): DHCP most likely not restarting pdns\_recursor

### 3.3.490 2020-11-02

- T3024 (bug): DHCPv6 PD configuration doesn't really render an expected behavior

### 3.3.491 2020-11-01

- T3036 (feature): OpenVPN remote-address does not accept IPv6 address
- T2193 (feature): Display disabled VRRP instances in a `show vrrp` output

### 3.3.492 2020-10-30

- T2790 (feature): Add ability to set ipv6 protocol route-map for OSPFv3
- T3033 (feature): Update Linux Kernel to v4.19.154
- T2969 (bug): OpenVPN: command\_set on interface is not applied, if interface doesn't come up in commit

### 3.3.493 2020-10-28

- T2631 (default): l2tp, sstp, pptp add option to disable radius accounting
- T2630 (feature): Allow Interface MTU over 9000
- T3027 (bug): Unable to update system Signature check FAILED
- T2995 (bug): Enhancements/bugfixes for vyos\_dict\_search()
- T2968 (feature): Add support for Intel Atom C2000 series QAT

### 3.3.494 2020-10-27

- T3026 (default): qemu: update script for deprecated ssh\_host\_port\_min/max
- T2938 (feature): Adding remote Syslog RFC5424 compatibility
- T2924 (bug): Using 'set src' in a route-map invalidates it as part of a subsequent boot-up
- T2587 (bug): Cannot enable the interface when the MTU is set to less than 1280
- T2885 (default): configd: print commit errors to config session terminal
- T2808 (default): Add smoketest to ensure script consistency with config daemon
- T2582 (default): Script daemon to offload processing during commit

- T1721 (bug): Recursive Next Hop not updated for static routes

### 3.3.495 2020-10-24

- T3007 (default): HTTP-API should use config load script, not backend config load
- T3009 (bug): vpn l2tp remoteaccess require option broken
- T3010 (bug): ttl option of gre-bridge
- T3005 (bug): Intel: update out-of-tree drivers, i40e driver warning
- T3004 (feature): ConfigSession should (optionally) use config load script
- T2723 (feature): Support tcptraceroute

### 3.3.496 2020-10-22

- T2978 (bug): IPoE service does not work on shared mode
- T2906 (bug): OpenVPN: tls-auth missing key direction

### 3.3.497 2020-10-21

- T2828 (bug): BGP conf\_mode error enforce-first-as
- T2749 (bug): Setting ethx configuration takes a long time
- T2138 (default): Can't load archived configs as they are gzipped

### 3.3.498 2020-10-20

- T2987 (bug): VxLAN not working properly after upgrading to latest October build and with a new installation
- T2989 (default): MPLS documentation expansion

### 3.3.499 2020-10-19

- T1588 (bug): VRRP failed to start if any of its interfaces not exist
- T1385 (feature): Allow bonding interfaces to have pseudo-ethernet interfaces
- T3000 (bug): Mismatch between "prefix-length" and "preference" in dhcp6-server syntax
- T2992 (feature): Automatically verify sha256 checksum on ISO download
- T752 (feature): Add an option to disable IPv4 forwarding on specific interface only

### 3.3.500 2020-10-18

- T2965 (feature): Brief BFD Peer Info
- T2907 (feature): OpenVPN: Option to disable encryption
- T2985 (feature): Add glue code to create bridge interface on demand

### 3.3.501 2020-10-17

- T2980 (bug): FRR bfdd crash due to invalid length
- T2991 (feature): Update WireGuard to 1.0.20200908
- T2990 (feature): Update Linux Kernel to v4.19.152
- T2981 (feature): MPLS LDP neighbor session clear capability
- T2792 (default): Failed to run `sudo make qemu` with vyos-build container due to the change of packer

### 3.3.502 2020-10-13

- T2976 (bug): Client IP pool does not work for PPPoE local users

### 3.3.503 2020-10-12

- T2951 (bug): Cannot enable logging for monitor nat
- T2782 (bug): Changing timezone, does not restart rsyslog

### 3.3.504 2020-10-06

- T2957 (bug): show openvpn not printing anything

### 3.3.505 2020-10-05

- T2963 (bug): Wireless: WIFI is not password protected when security wpa mode is not defined but passphrase is

### 3.3.506 2020-10-04

- T2953 (feature): Accel-PPP services CLI config cleanup (SSTP, L2TP, PPPoE, IPoE)
- T2829 (bug): PPPoE server: mppe setting is implemented as node instead of leafNode
- T2960 (feature): sstp: migrate to get\_config\_dict()

### 3.3.507 2020-10-03

- T2956 (feature): Add support for list of defaultValues
- T2955 (feature): Update Linux Kernel to v4.19.149

### 3.3.508 2020-10-02

- T2952 (bug): config: timeout breaks synchronization of messages, causing freeze

### 3.3.509 2020-10-01

- T2945 (bug): Interface removed from bridge on setting change
- T2948 (bug): NAT: OSError when configuring translation address range
- T2936 (feature): Migrate PPPoE server to get\_config\_dict() do reduce boilerplate code

### 3.3.510 2020-09-30

- T2939 (bug): Wireguard Remove Peer Fails

### 3.3.511 2020-09-29

- T2919 (feature): PPPoE server: Called-Station-Id attribute
- T2918 (feature): Accounting interim jitter for pppoe, l2tp, pptp, ipoe
- T2917 (feature): PPPoE server: Preallocate NAS-Port-Id
- T2937 (feature): Update Linux Kernel to v4.19.148

### 3.3.512 2020-09-27

- T2930 (feature): Support configuration of MAC address for VXLAN and GENEVE tunnel

### 3.3.513 2020-09-26

- T2856 (bug): equuleus: `show version all` throws broken pipe exception on abort
- T2929 (bug): Upgrading from 1.2 (crux) to 1.3 rolling causes vyos.configtree.ConfigTreeError for RADIUS settings
- T2928 (bug): MTU less then 1280 bytes and IPv6 will raise FileNotFoundError
- T2926 (bug): snmp.py missing an import
- T2912 (feature): When setting MTU check for hardware maximum supported MTU size

### 3.3.514 2020-09-25

- T2915 (bug): Lost "proxy-arp-pvlan" option for vlan
- T2925 (feature): Update Linux Kernel to v4.19.147
- T2921 (feature): Migrate "service dns forwarding" to get\_config\_dict() for ease of source maintenance

### 3.3.515 2020-09-24

- T2896 (bug): set ip route 0.0.0.0/0 dhcp-interface eth0
- T2923 (bug): Configuring DHCPv6-PD without a interface to delegate to raises TypeError

### 3.3.516 2020-09-23

- T2846 (bug): ip route doesn't show longer-prefixes

### 3.3.517 2020-09-20

- T2904 (feature): 802.1ad / Q-in-Q ethertype default not utilized
- T2905 (feature): Sync CLI nodes between PPPoE and WWAN interface
- T2903 (feature): Q-in-Q (802.1ad) ethertype should be defined explicitly and not via its raw value

### 3.3.518 2020-09-19

- T2894 (bug): bond: lacp: member interfaces get removed once bond interface has vlans configured
- T2901 (feature): Update Linux Kernel to v4.19.146
- T2900 (bug): DNS forwarding: invalid warning is shown for "system name-server" or "system name-servers-dhcp" even if present

### 3.3.519 2020-09-18

- T945 (bug): Unable to change configuration after changing it from script (vbash + script-template)

### 3.3.520 2020-09-16

- T2886 (bug): RADIUS authentication broken only returns operator level
- T2887 (bug): WiFi ht40+ channel width is not set in hostaptd.conf

### 3.3.521 2020-09-15

- T2515 (bug): Ethernet interface is automatically disabled when removing it from bond

### 3.3.522 2020-09-14

- T2872 (bug): "Show log" for nat and openvpn got intermixed
- T2301 (bug): Cannot delete PBR
- T2880 (feature): Update Linux Kernel to v4.19.145
- T2879 (feature): Cleanup 4.19.144 kernel configuration

### 3.3.523 2020-09-13

- T2858 (feature): Rewrite dynamic dns client to get\_config\_dict()
- T2857 (feature): Cleanup Intel QAT configuration script
- T2877 (feature): LACP / bonding: support configuration of minimum number of links

### 3.3.524 2020-09-12

- T2863 (default): Wireguard IPv6 Link-Local Addresses Are Not Unique
- T2876 (feature): Update Linux Kernel to v4.19.144

### 3.3.525 2020-09-10

- T2870 (feature): Update Linux Kernel to v5.8.8

### 3.3.526 2020-09-09

- T2728 (bug): Protocol option ignored for IPSec peers in transport mode
- T1934 (default): Change default hostname when deploy from OVA without params.
- T1953 (bug): DDNS service name validation rejects valid service names

### 3.3.527 2020-09-07

- T1729 (default): PIM (Protocol Independent Multicast) implementation

### 3.3.528 2020-09-06

- T2860 (bug): Update Accel-PPP to fix l2tp CVE

### 3.3.529 2020-09-02

- T2833 (bug): RIP outgoing update filter list no longer operational
- T2849 (bug): vyos.xml.defaults should return a list on multi nodes, by default

### 3.3.530 2020-08-31

- T2636 (bug): get\_config\_dict() shall always return a list on <multi/> nodes

### 3.3.531 2020-08-30

- T2843 (feature): Upgrade Linux Kernel to 5.8 series
- T2814 (default): kernel 5.1+ : NAT : module `nft\_chain\_nat\_ipv4` renamed
- T2839 (feature): Upgrade WireGuard user-space tools and Kernel module
- T2842 (feature): Replace custom "wireguard, wireguard-tools" package with debian-backports version

### 3.3.532 2020-08-29

- T2836 (default): show system integrity broken in 1.3

### 3.3.533 2020-08-28

- T2126 (bug): show vpn ipsec sa IPSec - Process NOT Running
- T2813 (bug): NAT: possible to commit illegal source nat without translation
- T1463 (bug): Missing command `show ip bgp scan` appears in command completion

### 3.3.534 2020-08-27

- T2832 (feature): Migrate vyos-smoketest content into vyos-1x

### 3.3.535 2020-08-26

- T2830 (default): Migrate "service https" to use `get_config_dict()`
- T2831 (feature): Update Linux Kernel to v4.19.142

### 3.3.536 2020-08-25

- T2826 (bug): frr: frr python lib error in `replace_section`

### 3.3.537 2020-08-24

- T2423 (bug): Loadkey scp ssh key errors

### 3.3.538 2020-08-23

- T2811 (bug): Cannot delete vpn anyconnect
- T2823 (bug): VXLAN has state A/D after configuration
- T2812 (default): Add basic smoketest for anyconnect

### 3.3.539 2020-08-22

- T2822 (feature): Update Linux Kernel to v4.19.141
- T2821 (feature): Support DHCPv6-PD without "address dhcpv6"
- T2677 (feature): Proposal for clearer DHCPv6-PD configuration options

### 3.3.540 2020-08-20

- T2209 (bug): Documentation has reference to the old 'user x level admin' option
- T1665 (default): prefix-list and prefix-list6 rules incorrectly accept a host address where prefix is required
- T2815 (default): Move certbot config directory under `/config/auth`

### 3.3.541 2020-08-19

- T2794 (bug): op-mode: lldp: "show lldp neighbors" `IndexError: list index out of range`
- T2791 (feature): "monitor traceroute" has no explicit IPv4/IPv6 support
- T1515 (bug): FRR ospf6d crashes when performing: "show ipv6 ospfv3 database"

### 3.3.542 2020-08-16

- T2277 (bug): dhclient-script-vyos does not support VRFs
- T2090 (default): Deleting 'service salt-minion' causes python TypeError

### 3.3.543 2020-08-15

- T2797 (feature): Update Linux Kernel to v4.19.139
- T2796 (bug): PPPoE-Server: listen interface is mandatory but validation check is missing

### 3.3.544 2020-08-14

- T2795 (bug): console server fails to commit

### 3.3.545 2020-08-12

- T2786 (bug): OSPF Interface Cost
- T2325 (bug): NHRP op-mode errors with missing daemon socket
- T2227 (feature): MPLS documentation
- T2767 (bug): The interface cannot be disabled for network enabled configuration
- T2316 (bug): DHCP-server op-mode errors

### 3.3.546 2020-08-11

- T2779 (bug): LLDP: "show lldp neighbors interface" does not yield any result
- T2379 (bug): DHCPv6 address for interface deletion triggers a script error
- T2784 (default): Remove unused arg from host\_name.py functions verify and get\_config

### 3.3.547 2020-08-10

- T2780 (feature): Update Linux Kernel to v4.19.138

### 3.3.548 2020-08-08

- T2716 (bug): Shaper-HFSC shapes but does not control latency correctly
- T2497 (default): Cache config string during commit
- T2501 (bug): Cannot recover from failed boot config load
- T1974 (feature): Allow route-map to set administrative distance
- T1949 (bug): Multihop IPv6 BFD is unconfigurable

### 3.3.549 2020-08-04

- T2758 (bug): router-advert: 'infinity' is not a valid integer number
- T2637 (bug): Vlan is not removed from the system
- T1287 (bug): No DHCPv6 leases reported for "show dhcpv6 client leases"

### 3.3.550 2020-08-03

- T2241 (default): Changing settings on an interface causes it to fall out of bridge
- T2757 (bug): "show system image version" contains additional new-line character breaking output
- T1826 (bug): Misleading message on "reboot at" command
- T1511 (default): Rewrite ethernet setup scripts to python
- T1600 (default): Convert 'ping' operation from vyatta-op to new syntax
- T1486 (bug): Unknown LLDP version reported to peers
- T1414 (enhancement): equuleus: buster: 10-unmountfs.chroot fail under apply
- T1076 (bug): SSH: make configuration (sshd\_config) volatile and store it to /run
- T2724 (feature): Support for IPv6 Toolset
- T2323 (bug): LLDP: "show lldp neighbors detail" returns warnings when service is not configured
- T1754 (bug): DHCPv6 client is impossible to restart

### 3.3.551 2020-08-02

- T2756 (feature): Accel-PPP: make RADIUS accounting port configurable

### 3.3.552 2020-08-01

- T2752 (bug): Exception when configuring unavailable ethernet interface
- T2751 (feature): Update Linux Kernel to v4.19.136
- T2753 (feature): Rewrite "add system image" op mode commands in XML
- T2690 (feature): Add VRF support to the add system image command

### 3.3.553 2020-07-30

- T2746 (feature): IPv6 link-local addresses not configured
- T2678 (bug): High RAM usage on SSH logins with lots of IPv6 routes in the routing table.
- T2701 (bug): `vpn ipsec pfs enable` doesn't work with IKE groups
- T2745 (feature): router-advert: migrate to get\_config\_dict()

### 3.3.554 2020-07-29

- T2743 (feature): WireGuard: move key migration from config script to migration script
- T2742 (feature): mDNS repeater: migrate to get\_config\_dict()

### 3.3.555 2020-07-28

- T1117 (feature): 'show ipv6 bgp route-map' missing
- T928 (feature): Add support for PIM (Protocol-Independent Multicast)

### 3.3.556 2020-07-27

- T2729 (feature): Pseudo-ethernet replace fail message
- T1249 (feature): multiple PBR rules can set to a single interface
- T1956 (feature): PPPoE server: support PAD0-delay
- T1295 (feature): FRR: update documentation
- T1222 (bug): OSPF routing problem - route looping
- T1158 (bug): Route-Map configuration dropped updating rc11 to epa2
- T1130 (bug): Deleting BGP communities from prefix does not work
- T2067 (feature): pppoe-server: Add possibility set multiple service-name

### 3.3.557 2020-07-26

- T2734 (feature): WireGuard: fwmark CLI definition is inconsistent
- T2733 (feature): Support MTU configuration on pseudo ethernet devices
- T2644 (default): Bonding interfaces cannot be disabled
- T2476 (bug): Bond member description change leads to network outage
- T2443 (feature): NHRP: Add debugging information to syslog
- T2021 (bug): OSPFv3 doesn't support decimal area syntax
- T1901 (bug): Semicolon in values is interpreted as a part of the shell command by validators
- T2000 (bug): strongSwan does not install routes to table 220 in certain cases
- T2091 (bug): swanctl.conf file is not generated properly if more than one IPsec profile is used
- T1983 (feature): Expose route-map when BGP routes are programmed in to FIB
- T1973 (feature): Allow route-map to match on BGP local preference value
- T1853 (bug): wireguard - disable peer doesn't work
- T1985 (feature): pppoe: Enable ipv6 modules without configured ipv6 pools

### 3.3.558 2020-07-25

- T2730 (feature): Update Linux Kernel to v4.19.134
- T2106 (bug): Wrong interface states after reboot
- T1507 (default): cli: logical redundancy with boolean type

### 3.3.559 2020-07-24

- T2097 (bug): Problems when using <path> as completion helper in op-mode
- T2092 (bug): dhcp-server rfc3442 static route should add default route
- T1817 (bug): BGP next-hop-self not working.
- T1462 (bug): Upgrade path errors 1.1.8 to 1.2.1-S2
- T1372 (bug): Diff functionality behaves incorrectly in some cases
- T2073 (feature): ipoe-server: reset op-mode command for sessions
- T1715 (bug): System DNS Server Order Incorrect

### 3.3.560 2020-07-23

- T2673 (bug): After the bridge is configured with Mac, bridge is automatically disabled
- T2626 (bug): Changing pseudo-ethernet mode, throws CLI error
- T2608 (bug): delete pseudo-ethernet failed (another error type)
- T2527 (bug): bonding: the last slave interface is not deleted
- T2358 (bug): ip6ip6 bridge conf\_mode errors
- T2346 (bug): Setting hostname yields temporary file error
- T2330 (bug): Vpn op-mode syntax
- T2188 (default): NTP op-mode commands don't work

### 3.3.561 2020-07-22

- T2718 (bug): ntp.conf updated incorrectly
- T2658 (bug): Interface description comment display error
- T2643 (bug): show interfaces does not scale with terminal width
- T2725 (bug): Config fails to load if user has no password
- T2707 (default): Allow alternative initialization data for Config

### 3.3.562 2020-07-20

- T2709 (bug): Destination NAT translation port without address fails to commit
- T2519 (bug): Broadcast address does not add automatically

### 3.3.563 2020-07-19

- T2708 (bug): "show flow-accounting" should not display script's "usage" help
- T2592 (default): dhcp-relay discarding packets on valid interfaces
- T2712 (feature): udp-broadcast-relay: service no longer starts
- T2706 (feature): Support NDP protocol monitoring

### 3.3.564 2020-07-18

- T2704 (bug): connect/disconnect Missing newline in op-mode tab completion helper
- T2689 (feature): Add helper functions to query changes between session and effective configs
- T2585 (bug): Unable to access the Internet after opening PPPoE on-demand dialing

### 3.3.565 2020-07-15

- T2675 (bug): DNS service failed to start
- T2596 (feature): Allow specifying source IP for 'add system image'

### 3.3.566 2020-07-12

- T1575 (default): `show snmp mib ifmib` crashes with IndexError
- T2696 (bug): Some bugfixes of vyatta-wanloadbalance

### 3.3.567 2020-07-11

- T2687 (feature): SNMP: change logic on v3 password encryption
- T2693 (bug): Dhcp6c cannot be restarted after PPPoE link is reset

### 3.3.568 2020-07-08

- T2692 (bug): Evaluate Setting Default Hash Policy to L3+L4
- T2646 (bug): Sysctl for IPv4 ECMP Hash Policy Not Set

### 3.3.569 2020-07-07

- T2691 (bug): Upgrade from 1.2.5 to 1.3-rolling-202007040117 results in broken config due to case mismatch
- T2389 (bug): BGP community-list unknown command
- T2686 (bug): FRR: BGP: large-community configuration is not applied properly after upgrading FRR to 7.3.x series

### 3.3.570 2020-07-06

- T2680 (bug): dhcp6c service cannot recover when it fails

### 3.3.571 2020-07-05

- T2684 (feature): Update Linux Kernel to v4.19.131
- T2685 (feature): Update Accel-PPP to fix SSTP client issues
- T2681 (bug): PPPoE stops negotiating IPv6

### 3.3.572 2020-07-04

- T2682 (bug): VRF aware services - connection no longer possible after system reboot

### 3.3.573 2020-07-03

- T2670 (default): Remove dependency on show\_config from get\_config\_dict
- T2676 (feature): NTP: migrate to get\_config\_dict() implementation

### 3.3.574 2020-07-02

- T2668 (default): get\_config\_dict: add get\_first\_key arg to utility function get\_sub\_dict

### 3.3.575 2020-07-01

- T2662 (default): get\_config\_dict includes node name as key only for tag and leaf nodes
- T2667 (feature): get\_config\_dict: Use utility function for non-empty path argument

### 3.3.576 2020-06-28

- T2660 (bug): XML: Python default dictionary does not obey underscore (\_) when flat is False

### 3.3.577 2020-06-27

- T2656 (bug): XML: Python default dictionary returns wrong dictionary level(s)

### 3.3.578 2020-06-26

- T2642 (bug): sshd fails to start due to configuration error
- T2588 (default): Add support for default values to the interface-definition format
- T2622 (bug): Pseudo-ethernet interface config disappears across versions
- T2057 (feature): Generalised Interface configuration
- T2625 (feature): Provide generic Library for package builds

### 3.3.579 2020-06-25

- T2487 (bug): VRRP does not display info when group disabled
- T2329 (bug): Show remote config openvpn
- T2165 (bug): When trying to add route to ripng it complains that ip address should be IPv4 format
- T2159 (default): webproxy log read from wrong file
- T2101 (feature): Fix VXLAN config option parsing
- T2062 (bug): Wrong dhcp-server static route subnet bytes
- T1986 (bug): Python configuration manipulation library leaks open files
- T1762 (bug): VLAN interface configuration fails after internal representation of edit level was switched from a string to a list
- T1538 (bug): Update conntrack-sync packages to fix VRRP issues
- T1808 (feature): add package nftables

### 3.3.580 2020-06-24

- T2634 (feature): remove autogeneration of interface "ip section" from vyatta-cfg-system
- T2633 (bug): Error with arp\_accept on tun interface
- T2595 (feature): Update Linux Kernel to v4.19.128
- T1938 (bug): syslog doesn't start automatically

### 3.3.581 2020-06-23

- T2632 (bug): WireGuard: Cannot use only one preshared-key for one peer
- T1829 (bug): Install Image script does not respect size of partition greater than 2G but less than disk size
- T2635 (feature): SSH: migrate to get\_config\_dict()

### 3.3.582 2020-06-22

- T2486 (bug): DNS records set via 'system static-host-mapping' return NXDOMAIN from 'service dns forwarding' after a request to a forwarded zone
- T2463 (bug): DHCP-received nameserver not added to vyos-hostsd
- T2534 (bug): pdns-recursor override.conf error
- T2054 (bug): Changing "system name-server" doesn't update dns forwarding config, neither does "restart dns forwarding"
- T2225 (default): PIM/IGMP documentation

### 3.3.583 2020-06-21

- T2624 (feature): Serial Console: fix migration script for configured powersave and no console
- T2610 (bug): default-lifetime is not reflected in the RA message
- T2299 (feature): login radius-server priority
- T1739 (bug): Serial interface seems not to be deleted properly
- T480 (bug): Error if no serial interface is present (/dev/ttyS0: not a tty)

### 3.3.584 2020-06-20

- T2621 (bug): show interfaces repeats interface description if it is longer then an arbitrary number of characters
- T2618 (default): Conversion from 1.2 to 1.3 lost RADVD prefix autonomous-flag setting

### 3.3.585 2020-06-19

- T2589 (bug): delete pseudo-ethernet failed
- T2490 (feature): Add serial (rs232) to ssh bridge service

### 3.3.586 2020-06-18

- T2614 (default): Add an option to mangle dict keys to `vyos.config.get_config_dict()`
- T2026 (default): Make `cli-shell-api` correctly exit with non-zero code on failures
- T1868 (default): Add opportunity to get current values from API

### 3.3.587 2020-06-17

- T2478 (feature): login radius: use NAS-IP-Address if defined source address
- T2141 (bug): Static ARP is not applied on boot
- T2609 (bug): router-advert: radvd does not start when lifetime is improperly configured
- T1720 (feature): support for more 'show ip route' commands

### 3.3.588 2020-06-16

- T2604 (default): Remove use of `is_tag` in `system-syslog.py`
- T2605 (bug): SNMP service is not disabled by default
- T2568 (bug): Add some missing checks in config
- T2156 (default): PIM op-mode commands

### 3.3.589 2020-06-15

- T2600 (bug): RADIUS system login configuration rendered wrongly
- T2599 (bug): "show interfaces" does not list VIF interfaces in ascending order
- T2591 (bug): show command has wrong interfaces ordering
- T2576 (bug): "show interfaces" does not return VTI

### 3.3.590 2020-06-14

- T2354 (bug): Wireless `conf_mode` errors
- T2593 (bug): source NAT translation port can not be set when translation address is set to masquerade
- T2594 (default): Missing firmware for `iwlwifi`

### 3.3.591 2020-06-11

- T2578 (bug): `ipaddrcheck` unaware of /31 host addresses - can no longer assign /31 mask to interface addresses
- T2571 (bug): NAT destination port with `!` results in error
- T2570 (feature): Drop support for "system console device <device> modem"
- T2586 (bug): WWAN default route is not installed into VRF
- T2561 (feature): Drop support for "system console netconsole"
- T2569 (feature): Migrate "set system console" to XML and Python representation

### 3.3.592 2020-06-10

- T2575 (bug): `pppoe-server`: does not possibly assign IP address
- T2565 (bug): Cannot connect to l2tp server with radius auth
- T2553 (bug): set interface `ethN vif-s nnnn` does not commit

### 3.3.593 2020-06-08

- T2559 (feature): Add operational mode command to retrieve hardware sensor data

### 3.3.594 2020-06-07

- T2529 (feature): WWAN: migrate from `ttyUSB` device to new device in `/dev/serial/by-bus`
- T2560 (feature): New op-mode command to display information about USB interfaces

### 3.3.595 2020-06-05

- T2548 (bug): Interfaces allowing inappropriate network addresses to be assigned
- T1958 (default): Include only firmware we actually need

### 3.3.596 2020-06-04

- T2514 (enhancement): "mac" setting for bond members

### 3.3.597 2020-06-02

- T2129 (feature): XML schema: `tagNode` not allowed on first level in new XML op-mode definition
- T2545 (feature): Show physical device offloading capabilities for specified ethernet interface
- T2544 (feature): Enable Kernel `KONFIG_KALLSYMS`
- T2543 (feature): Kernel: always build perf binary but ship as additional deb package to not bloat the image

- T1096 (bug): BGP process memory leak

### 3.3.598 2020-06-01

- T2535 (feature): Update Intel QAT drivers to 1.7.1.4.9.0-00008
- T2537 (feature): Migrate "show log dns" from vyatta-op to vyos-lx
- T2536 (bug): "show log dns forwarding" still refers to dnsmasq
- T2538 (feature): Update Intel NIC drivers to recent release (preparation for Kernel >=5.4)
- T2526 (feature): Wake-On-Lan CLI implementation

### 3.3.599 2020-05-31

- T2532 (feature): VRF aware OpenVPN

### 3.3.600 2020-05-30

- T2388 (feature): template rendering should create folder and set permission
- T2531 (feature): Update Linux Kernel to v4.19.125
- T2530 (bug): Error creating VRF with a name of exactly 16 characters

### 3.3.601 2020-05-29

- T2528 (bug): "update dns dynamic" throws FileNotFoundError excepton

### 3.3.602 2020-05-28

- T1291 (default): Under certain conditions the VTI will stay forever down

### 3.3.603 2020-05-27

- T2395 (feature): HTTP API move to flask/flask-restx as microframework
- T1121 (bug): Can't search for prefixes by community: Community malformed: AA:NN

### 3.3.604 2020-05-26

- T2520 (bug): show conntrack fails with Perl error
- T2502 (bug): PPPoE default route not installed for IPv6 when "default-route auto"
- T2458 (feature): Update FRR to 7.3.1
- T2506 (feature): DHCPv6-PD add prefix hint CLI option

### 3.3.605 2020-05-25

- T2391 (bug): pppoe-server session-control does not work
- T2269 (feature): SSTP specify tunnels names
- T1137 (bug): 'sh ip bgp sum' being truncated

### 3.3.606 2020-05-22

- T2491 (feature): MACsec: create CLI for replay protection
- T2489 (feature): Add MACsec interfaces to "show interfaces" output
- T2201 (feature): Rewrite protocol BGP [op-mode] to new XML/Python style
- T2492 (feature): Do not set encrypted user password when it is not changed
- T2496 (feature): Set default to new syntax for config file component versions
- T2493 (feature): Update Linux Kernel to v4.19.124
- T2380 (bug): After PPPoE 0 is restarted, the default static route is lost

### 3.3.607 2020-05-21

- T1876 (bug): IPSec VTI tunnels are deleted after rekey and dangling around as A/D
- T2488 (feature): Remove logfile for dialup interfaces like pppoe and wwan
- T2475 (bug): linting
- T1820 (bug): VRRP transition scripts for sync-groups are not supported in VyOS (anymore)
- T2364 (default): Add CLI command for mroute
- T2023 (feature): Add support for 802.1ae MACsec

### 3.3.608 2020-05-20

- T2480 (bug): NAT: after rewrite commit tells that dn timer IP address is not locally connected

### 3.3.609 2020-05-19

- T2481 (feature): WireGuard: support tunnel via IPv6 underlay
- T421 (bug): Add Pv6 prefix delegation support
- T815 (feature): Add DHCPv6 server prefix-delegation support

### 3.3.610 2020-05-17

- T2471 (feature): PPPoE server: always add AdvAutonomousFlag when IPv6 is configured
- T2409 (default): At boot, effective config should not be equal to current config

### 3.3.611 2020-05-16

- T2466 (bug): live-build encounters apt dependency problem when building with local packages
- T2470 (feature): Update to PowerDNS recursor 4.3
- T2469 (feature): Update Linux Kernel to v4.19.123
- T2198 (default): Rewrite NAT in new XML/Python style

### 3.3.612 2020-05-15

- T2449 (bug): 'ipv6 address autoconf' and 'address dhcpv6' don't work because interfaces have accept\_ra=1 (they should have accept\_ra=2 when forwarding=1)

### 3.3.613 2020-05-14

- T2456 (bug): netflow source-ip cannot be configured

### 3.3.614 2020-05-13

- T2435 (bug): Pseudo-ethernet Interfaces Broken
- T2294 (bug): ipoe-server broken (jinja2 template issue)

### 3.3.615 2020-05-12

- T2454 (feature): Update Linux Kernel to v4.19.122
- T2392 (bug): SSTP with ipv6

### 3.3.616 2020-05-10

- T2445 (bug): VRF route leaking for ipv4 not working
- T2372 (bug): VLAN: error on commit if main interface is disabled
- T2439 (bug): Configuration dependency problem, unable to load complex configuration after reboot

### 3.3.617 2020-05-09

- T2427 (default): Interface addressing broken since fix for T2372 was merged
- T2438 (default): isc-dhcp-server(6).service reports startup success immediately even if dhcpd fails to start up
- T2367 (default): Flush addresses from bridge members

### 3.3.618 2020-05-08

- T2441 (bug): TZ validator has a parse error
- T2429 (bug): Vyos cannot apply VLAN sub interface to bridge

### 3.3.619 2020-05-06

- T2402 (bug): Live ISO should warn when configuring that changes won't persist

### 3.3.620 2020-05-05

- T1899 (bug): Unionfs metadata folder is copied to the active configuration directory

### 3.3.621 2020-05-04

- T2412 (bug): ping flood does not work as unprivileged user
- T701 (bug): LTE interface dosen't come up
- T951 (bug): command 'isolate-stations true/false' does not make any changes in the hostapd.conf

### 3.3.622 2020-05-03

- T2420 (feature): Update Linux Kernel to v4.19.120
- T2406 (feature): DHCPv6 CLI improvements
- T2421 (feature): Update WireGuard to Debian release 1.0.20200429-2\_bpo10+1

### 3.3.623 2020-05-02

- T2414 (feature): Improve runtime from Python numeric validator
- T2413 (feature): Update Linux Kernel to v4.19.119

### 3.3.624 2020-05-01

- T2411 (feature): op-mode: make "monitor traceroute" VRF aware
- T2347 (bug): During commit, any script output directed to stdout will contain path
- T2239 (default): build-vmware-image script ignores the predefined file path, uses the environment variable unconditionally.

### 3.3.625 2020-04-29

- T2399 (bug): op-mode "dhcp client leases" does not return leases
- T2398 (bug): op-mode "dhcp client leases interface" completion helper misses interfaces
- T2394 (feature): dhcpv6 client does not start
- T2393 (feature): dhclient: migrate from SysVinit to systemd
- T2268 (bug): DHCPv6 is broken

### 3.3.626 2020-04-28

- T1227 (bug): rip PW can't be set at interface config

### 3.3.627 2020-04-27

- T2373 (feature): Required auth options for pppoe-server
- T1381 (feature): Enable DHCP option 121 processing
- T2010 (bug): Reboot at reports wrong time or missing timezone

### 3.3.628 2020-04-26

- T2386 (bug): salt: upgrade to 2019.2 packages
- T2385 (bug): salt-minion: improve completion helpers
- T2384 (bug): salt-minion: log to syslog and remove custom logging option
- T2383 (feature): Update Linux Kernel to v4.19.118
- T2382 (bug): salt-minion: Throws KeyError on commit
- T2350 (bug): Interface geneve conf-mode error

### 3.3.629 2020-04-25

- T2304 (feature): "system login" add RADIUS VRF support
- T1842 (bug): Equuleus: "reboot at 04:00" command not working

### 3.3.630 2020-04-24

- T2375 (feature): WireGuard: throw exception if address and port are not given as both are mandatory
- T2348 (bug): On IPv6 address distribution and DHCPv6 bugs

### 3.3.631 2020-04-23

- T2369 (feature): VRF: can not leak interface route from default VRf to any other VRF
- T2368 (bug): VRF: missing completion helper when leaking to default table
- T2374 (bug): Tunnel interface can not be disabled
- T2362 (default): IPv6 link-local addresses missing due to EUI64 address code, causing router-advert not to work
- T2345 (default): IPv6 router-advert not working

### 3.3.632 2020-04-22

- T2361 (bug): Unable to delete VLAN vif interface
- T2339 (bug): OpenVPN: IPv4 no longer working after adding IPv6 support
- T2331 (bug): VRRP op-mode errors
- T2320 (bug): Wireguard creates non-existing interfaces in [op-mode].
- T2096 (feature): Provide "generate" and "show" commands via the http API
- T2351 (feature): Cleanup PPTP server implementation and CLI commands

### 3.3.633 2020-04-21

- T2341 (bug): Pseudo-ethernet Interfaces Not Loaded on Boot
- T2270 (bug): using load with scp/sftp and a username and password does not work
- T2255 (bug): DNS forwarding op-mode error
- T1907 (bug): Traceback on a non-existent interface.
- T2204 (feature): Support tunnel source-interface

### 3.3.634 2020-04-20

- T2335 (bug): Unable to assign IPv6 from ISP
- T2317 (bug): l2tp overwriting ipsec config files
- T2292 (bug): Ensure graceful shutdown of vyos-http-api
- T2344 (bug): PPPoE server client static IP assignment silently fails

### 3.3.635 2020-04-19

- T2337 (default): hw-id gone missing from interfaces after upgrade to 1.3-rolling-202004191028
- T2340 (feature): Remove informational "sg" messages from syslog
- T2338 (bug): Can't delete static IPv6 route on vrf
- T2336 (bug): OpenVPN service fails to start
- T2308 (default): openvpn op-mode scripts broken after migrating to systemd service
- T2185 (default): Start daemons with systemd units instead of with start-stop-daemon

### 3.3.636 2020-04-18

- T2318 (bug): dns-forwarding migration script breaks with invalid interface name
- T2319 (feature): Update Linux Kernel to v4.19.116
- T2314 (feature): Cleanup PPPoE server implementation and CLI commands
- T2313 (bug): Accel-PPP / PPPoEserver raises "Floating point exception" when not all limits are defined
- T2312 (feature): Use LED modules to enable more visible feedback on VyOS hardware chassis
- T2306 (feature): Add new cipher suites to the WiFi configuration
- T2286 (default): IPoE server vulnerability
- T2224 (feature): Update Linux Kernel to v4.19.114
- T2110 (feature): RADIUS: supply include file for radius config to have a uniform CLI
- T2324 (feature): Cleanup IPoE server implementation and CLI commands

### 3.3.637 2020-04-17

- T2275 (bug): flow-accounting broken in rolling
- T2256 (feature): Accel-ppp op-mode syntax

### 3.3.638 2020-04-16

- T2295 (bug): Passwords with Special Characters Broken
- T2305 (feature): Add release name to "show version" command
- T2235 (default): OpenVPN server client IP doesn't reserve that IP in the pool
- T149 (feature): IPv6 support in OpenVPN tunnel

### 3.3.639 2020-04-15

- T2293 (bug): OpenVPN: UnboundLocalError after merging server\_network PullRequest
- T2298 (bug): Errors PDNS with name-server set

### 3.3.640 2020-04-14

- T2213 (bug): vyos-1x: WiFi mode ieee80211ac should also activate ieee80211n

### 3.3.641 2020-04-13

- T2283 (default): openvpn not starting: ccd path in template not moved to /run/openvpn/ccd
- T2236 (bug): DMVPN broken after tunnel rewrite to XML/Python
- T2284 (default): Upgrade ddclient to 3.9.1 which also brings systemd files
- T2282 (feature): Clarify hw-id in ethernet and wireless interface nodes
- T611 (feature): Static route syntax should reflect `ip` command routing capabilities, if possible.

### 3.3.642 2020-04-12

- T2273 (default): OpenVPN no longer starts in latest rolling, migrate to systemd
- T2263 (feature): Reset feature for SSTP sessions
- T2262 (bug): Broken reset commands for pptp and l2tp
- T2031 (bug): pseudo-ethernet link interface cannot be changed

### 3.3.643 2020-04-11

- T2264 (feature): l2tp: cleanup CLI definition
- T2233 (bug): Typos in wlanX.cfg
- T2238 (bug): After re-writing list\_interfaces.py to use Interfaces() pseudo-ethernet is missing

### 3.3.644 2020-04-10

- T2265 (feature): DHCP to be an attribute of the class instead of a inheritance
- T2261 (bug): "client-config-dir" not being set for openvpn
- T2248 (bug): PPPoE Broken in Latest 1.3 Rolling (1.3-rolling-202004070629)
- T1629 (bug): IP addresses configured on vif-s interfaces are not added to the system
- T2266 (default): openvpn bridged client-server doesn't work (validation error)
- T2253 (default): Fix use of cmd in merge config and remote function helpers

### 3.3.645 2020-04-09

- T2260 (feature): vxlan, pseudo-ethernet: convert link nodes to source-interface
- T2172 (feature): Enable conf VXLAN without remote address
- T2237 (bug): l2tp, pptp, pppoe wrong chap-secrets file

### 3.3.646 2020-04-08

- T2244 (feature): WireGuard: cleanup Python implementation and reduce amount of boilerplate code
- T2186 (feature): Provide more information to the user when a traceback is reported to the user
- T2246 (bug): LLDP op-mode error
- T2240 (feature): Support for bind vif-c interfaces into VRFs
- T2160 (feature): Allow restricting HTTP API to specific virtual hosts
- T2247 (feature): WireGuard: add VRF support

### 3.3.647 2020-04-05

- T2212 (bug): vyos-1x: WiFi card antenna count not set accordingly
- T2230 (feature): Split out inlined Jina2 template to data/templates folder
- T2206 (feature): Split WireGuard endpoint into proper host and port nodes

### 3.3.648 2020-04-04

- T2158 (bug): Commit fails if ethernet interface doesn't support flow control (pause)
- T2221 (bug): Ability to remove a VRF that has a next-hop-vrf as target
- T2211 (bug): vyos-1x: VHT channel width not set accordingly
- T2208 (bug): vyos-1x: commit on interfaces wireless wlanX capabilities vht link-adaptation (both|unsolicited) fails
- T2183 (bug): A number of bugs with wireguard script due to interface rearrangement
- T2104 (default): ifconfig.py size

- T2028 (feature): Convert "interfaces tunnel" to new XML/Python representation
- T2219 (bug): VRF default route of PPPoE and WWAN interfaces do not get added into proper routing table
- T2222 (default): openvpn: requires "multihome" option to listen on all addresses with udp protocol

### 3.3.649 2020-04-02

- T2072 (bug): Shell autocomplete of option (config node) with quoted value doesn't work
- T1823 (feature): l2tpv3 interface migration fails
- T2202 (feature): Update PowerDNS recursor to 4.2 series
- T2200 (feature): Add VRF support on wirelessmodem interfaces

### 3.3.650 2020-03-31

- T2166 (bug): Broken proxy-arp on vif
- T2180 (bug): get\_config\_dict should be independent of CLI edit level
- T2053 (default): Update vyos-load-config.py for version string syntax change
- T2052 (default): Update vyos-merge-config.py for version string syntax change
- T2144 (default): vyos-build: docker: selection of text in the terminal still selects it in vim (mouse isn't completely disabled)

### 3.3.651 2020-03-30

- T2176 (default): 'WiFiIf' object has no attribute 'set\_state'
- T2029 (feature): Switch to new syntax for config file component versions

### 3.3.652 2020-03-29

- T2178 (bug): VRF interface don't get removed when VRF is deleted
- T2170 (feature): Add ability to create static route from default to VRF
- T1831 (feature): Denest IPv6 router-advert from Interfaces to general service

### 3.3.653 2020-03-28

- T2167 (bug): vyos.ifconfig.get\_mac() broken
- T2151 (default): wireless: can't delete interface present in config but not present in system
- T1988 (feature): Migrate wirelessmodem to new XML/Python style interface

### 3.3.654 2020-03-27

- T2164 (bug): Package libstrongswan-standard-plugins missing from image
- T2105 (bug): wireless: not possible to disabled wlan0
- T2169 (default): Remove redundant use of show\_config in vyos-merge-config

### 3.3.655 2020-03-26

- T2162 (default): migration script for router-advert sets link-mtu 0 on bridge interfaces
- T1735 (bug): Issue in "show vpn ipsec/ike sa" output with ipsec encryption algorithm aes128gcm128/aes256gcm128/chacha etc

### 3.3.656 2020-03-25

- T2148 (default): openvpn: setting "server client" config without "server client ip" results in ValueError: ' ' does not appear to be an IPv4 or IPv6 address
- T2146 (default): openvpn: "delete server client" doesn't delete the corresponding ccd configs

### 3.3.657 2020-03-24

- T2157 (default): Organize service https listen-address/listen-port/server-name under 'virtual-host' node
- T1845 (bug): syslog host no longer accepts a port

### 3.3.658 2020-03-22

- T2150 (feature): SSTP ssl certificates can only be stored in /config/user-data/sstp
- T2149 (feature): Update Linux Kernel to v4.19.112
- T476 (enhancement): Update the base system to Debian 10 (Buster)

### 3.3.659 2020-03-21

- T2142 (bug): vyos-build: Add required packages and step to build-GCE-image script
- T1870 (feature): Extend Pipeline scripts to support PullRequests

### 3.3.660 2020-03-20

- T2006 (bug): SSTP RADIUS CLI accepts invalid values
- T2140 (default): openvpn: tls file check function checkCertHeader returns True even when no match is found
- T2007 (feature): SSTP accepts client MTU up to 16384 bytes
- T2008 (feature): Adjustment of SSTP CLI to be more consistent to the rest of VyOS

### 3.3.661 2020-03-19

- T2135 (bug): Login banner missing spacing now
- T2132 (feature): Document kernel boot parameter 'vyos-config-debug'
- T1744 (default): Config load fails in ConfigTree with ValueError: Failed to parse config: lexing: empty token

### 3.3.662 2020-03-17

- T2134 (bug): VXLAN: `NameError: name 'config' is not defined`

### 3.3.663 2020-03-16

- T2131 (feature): Improve syslog remote host CLI definition

### 3.3.664 2020-03-15

- T2122 (feature): Update Intel out-of-tree drivers to latest version(s)
- T2121 (feature): Update Linux Kernel to v4.19.109
- T2119 (bug): Error on boot when removing ethernet interface from VM

### 3.3.665 2020-03-14

- T834 (feature): New L2TP server implementation based on accel-ppp

### 3.3.666 2020-03-13

- T1622 (default): Add failsafe and back trace to boot config loader

### 3.3.667 2020-03-11

- T1961 (bug): VXLAN - fails to commit due to non-existent variable, broken MTU
- T2084 (default): conntrack-tools package build error for current/equuleus

### 3.3.668 2020-03-10

- T1331 (bug): DNS stops working

### 3.3.669 2020-03-09

- T2111 (feature): VRF add route leaking support
- T2109 (bug): Ping by name broken in VyOS 1.3-rolling-202003080217
- T2065 (bug): VyOS 1.3 Don't set daemon in openvpn-{intf}.conf file
- T31 (feature): Add VRF support

### 3.3.670 2020-03-08

- T1954 (bug): Having `system login radius` configured causes exponentially long boot times
- T1760 (bug): RADIUS shared secret is not redacted from "show configuration" op mode command

### 3.3.671 2020-03-07

- T2107 (bug): Wireless interfaces do not work in station mode without security

### 3.3.672 2020-03-05

- T2074 (bug): VyOS docker container: Cannot configure ethernet interface

### 3.3.673 2020-03-04

- T2098 (bug): Wrong call to cli-shell-api in generated op-mode templates for path completion helper

### 3.3.674 2020-03-03

- T2095 (bug): Copy command errors out

### 3.3.675 2020-03-01

- T2082 (bug): WireGuard broken after merging T2057
- T2089 (feature): RADIUS: do not query servers when commit is running started from a non RADIUS user
- T2086 (feature): Move sudo session open/close log entries to auth.log

### 3.3.676 2020-02-29

- T2046 (feature): allowing sub-classes of Interface to redefine how the interface is created

### 3.3.677 2020-02-28

- T2083 (default): vyos-build: build-packages fails at mdns-repeater due to wrong branch
- T2080 (default): traffic-policy shaper error when setting bandwidth

### 3.3.678 2020-02-27

- T2075 (feature): Add support for OpenVPN tls-crypt file option
- T2068 (feature): Update Linux Kernel to v4.19.105
- T1703 (default): Macvlan PPPoE support
- T2078 (feature): Kernel: remove unused RAID functions 5,6,10,jbod,dm

### 3.3.679 2020-02-25

- T2070 (feature): Rewrite (dis-)connect op-mode commands in XML and Python
- T2071 (feature): Add possibility to temporary disable a RADIUS server used for system login

### 3.3.680 2020-02-23

- T2055 (feature): Remove IPv6 router-advert options for PPPoE
- T1318 (feature): PPPoE client CLI redesign

### 3.3.681 2020-02-22

- T2063 (feature): vyos-salt-minion package is missing from vyos-world

### 3.3.682 2020-02-20

- T1969 (default): OSPF with WireGuard cause Route Inactive

### 3.3.683 2020-02-18

- T2034 (default): Removal of interfaces loopback lo removed 127.0.0.1 and ::1

### 3.3.684 2020-02-17

- T2047 (feature): Update Linux Kernel to v4.19.104
- T2048 (bug): ISO boot fails when wireless adapter is present

### 3.3.685 2020-02-16

- T2043 (bug): Bond VLANs can't be extended on the fly
- T2030 (bug): Bond doesn't survive reboot
- T1992 (bug): Adding vlan on a bond resets all BGP connections on same bond
- T1908 (feature): Add zone option for Cloudflare DDNS
- T1246 (bug): VyOS 1.2.0 "openvpn-options" configuration does not allow quotes in values

### 3.3.686 2020-02-15

- T2042 (bug): Error on reboot after deleting "service snmp" and not "service lldp snmp enable"
- T2041 (bug): Adding non existent bond interface raises exception

### 3.3.687 2020-02-14

- T2039 (bug): Wrong system type displayed in show version
- T2040 (bug): vyos-http-api-server should reload Config in all routes

### 3.3.688 2020-02-13

- T2033 (feature): Drop vyos-replace package
- T1635 (feature): Rewrite interface pseudo-ethernet in new XML/Python style

### 3.3.689 2020-02-10

- T2024 (feature): Migrate "system login banner" to XML/Python

### 3.3.690 2020-02-09

- T2022 (bug): When RADIUS config is active, local logins won't work
- T2020 (default): Unable to log in after upgrade to 1.3-rolling-202002080217
- T1931 (bug): Enabling SNMP commit error

### 3.3.691 2020-02-05

- T1948 (bug): RADIUS login broken in 1.3
- T1990 (feature): Migrate "system login" to XML/Python representation
- T1585 (default): Add letsencrypt/certbot support for 'service https'

### 3.3.692 2020-02-04

- T1965 (bug): VyOS-1.3: ping no longer supports specifying interface or source

### 3.3.693 2020-02-02

- T2011 (feature): Update Linux Kernel to v4.19.101
- T640 (bug): Images no longer work when built without "recommended" packages

### 3.3.694 2020-02-01

- T2009 (bug): Ethernet Interface always stays down
- T1989 (bug): conf.get\_config\_dict() throws exception

### 3.3.695 2020-01-31

- T1768 (bug): PPtP - vyos.config rewrite
- T2002 (bug): VLAN interfaces try to be enabled even if parent interface is A/D

### 3.3.696 2020-01-30

- T1994 (default): lldpd not bound to specified interfaces - Fix jinja template
- T1896 (enhancement): Remove LLDP-MED civic\_based location information
- T1724 (feature): wireguard - add endpoint check in verify()

### 3.3.697 2020-01-29

- T1996 (feature): Update Linux Kernel to 4.19.99
- T1862 (default): Use regex pattern \s+ to split strings on whitespace in Python 3.7
- T1755 (bug): Python KeyError exceptions raised with 'show vpn ipsec sa' command under use of certain IPSEC cipher suites
- T1747 (bug): L2TP breaks after upgrading to VyOS 1.2-rolling-201910180117 [issue report and proposed solution]
- T1664 (bug): Ipoe with bond per vlan don't work
- T1895 (feature): There is not restriction on selection of syslog facility
- T1670 (feature): OpenVPN option for tls-auth

### 3.3.698 2020-01-26

- T1937 (bug): snmpd throwing a tremendous amount of errors
- T1767 (bug): IPoE - vyos.config rewrite
- T1765 (bug): wireguard - vyos.config rewrite

### 3.3.699 2020-01-24

- T1975 (bug): OpenVPN tap devices won't come up automatically

### 3.3.700 2020-01-23

- T1766 (bug): service-pppoe - vyos.config rewrite

### 3.3.701 2020-01-21

- T1784 (bug): DMVPN with IPSec does not work in HUB mode
- T1977 (bug): webproxy error on fresh install

### 3.3.702 2020-01-18

- T1830 (feature): 1.3-rolling boots to GRUB prompt post-install on UEFI systems
- T1940 (bug): EFI Fresh Install fails to boot, 4K Sector Drives Fail to boot EFI

### 3.3.703 2020-01-16

- T1880 (default): "A stop job is running for live-tools - System Support Scripts" hangs, times out when shutting down equuleus live iso

### 3.3.704 2020-01-15

- T1959 (bug): Error message when adding IPSec VPN

### 3.3.705 2020-01-09

- T1955 (feature): snmp - cli config val\_help missing
- T1813 (bug): error in generated /etc/hosts file

### 3.3.706 2020-01-08

- T1946 (bug): Recovery ifname for PPTP remote-access

### 3.3.707 2020-01-03

- T1939 (feature): Provide abstraction for interface "ip" options

### 3.3.708 2020-01-01

- T1779 (bug): Tunnel interfaces aren't suggested as being available for bridging

### 3.3.709 2019-12-31

- T1654 (bug): sFlow: multiple "sflow server" not work, and "disable-imt" could break configuration
- T1923 (feature): Migrate L2TPv3 interface to XML/Python

### 3.3.710 2019-12-30

- T1920 (bug): beep: Error: Running under sudo, which is not supported for security reasons.
- T1918 (bug): l2tp / ipsec config broken in latest daily
- T1897 (bug): IPSec - 1.2 to 1.3 migration failed
- T1921 (bug): snmp: VyOS options no longer recognized
- T1922 (feature): Add VXLAN IPv6 support
- T1919 (feature): Migrate "system options" to XML/Python representation

### 3.3.711 2019-12-28

- T1916 (feature): Update Linux Kernel to v4.19.91
- T1915 (bug): Remove "system ipv6 blacklist" option
- T1912 (feature): Migrate "system (ip|ipv6)" to XML/Python representation

### 3.3.712 2019-12-27

- T1910 (bug): Invalid parmissions on latest 1.3 rolling ISO images

### 3.3.713 2019-12-26

- T1794 (bug): Interface description can't contain a colon
- T1906 (feature): Migrate "system time-zone" configuration to XML/Python

### 3.3.714 2019-12-23

- T1898 (enhancment): Support multiple IPv4/IPv6 LLDP management addresses
- T1878 (bug): accel-ppp: pppoe single-session option implementation

### 3.3.715 2019-12-22

- T393 (enhancment): Migrate vyatta-lldpd to vyos-lx

### 3.3.716 2019-12-20

- T1892 (default): vyos-build: Do not install recommends in docker image [enhancement]
- T1411 (enhancment): equuleus: buster: vyatta-ravpn: libfreeradius-client2 is missing in buster

### 3.3.717 2019-12-19

- [T1873](#) (default): DHCP server fails to start due to a change in isc-dhcp-server init scripts

### 3.3.718 2019-12-18

- [T1889](#) (bug): Error building docker build image
- [T1132](#) (default): Build on Debian Buster

### 3.3.719 2019-12-17

- [T1886](#) (feature): Update Linux Kernel to v4.19.89
- [T1887](#) (feature): Update WireGuard to Debian release 0.0.20191212-1

### 3.3.720 2019-12-13

- [T1861](#) (default): hosts lost after modified static-host-mapping

### 3.3.721 2019-12-10

- [T1843](#) (feature): Add GCC preprocessor support for XML files

### 3.3.722 2019-12-08

- [T1566](#) (feature): Extend L2TP/IPSec server with IPv6

### 3.3.723 2019-12-07

- [T1714](#) (bug): Disable DHCP Nameservers Not Working

### 3.3.724 2019-12-06

- [T1860](#) (feature): Update WireGuard to Debian release 0.0.20191127-2
- [T1859](#) (feature): Update Linux Kernel to v4.19.88
- [T1854](#) (bug): Dynamic DNS configuration cannot be deleted
- [T1849](#) (bug): DHCPv6 client does not start
- [T1169](#) (bug): LLDP potentially broken
- [T586](#) (bug): Cannot add ethernet vif-s vif-c interface to bridge-group

### 3.3.725 2019-12-05

- T1847 (bug): `set_level` incorrectly handles path given as empty string

### 3.3.726 2019-12-04

- T1787 (default): Failed config migration from V1.2.3 to 1.2-rolling-201911030217
- T1212 (bug): IPSec Tunnel to Cisco ASA drops reliably after 4.2GB transferred
- T1704 (feature): OpenVPN - Add support for ncp-ciphers

### 3.3.727 2019-12-03

- T1782 (bug): `pppoe0`: showing as "Coming up"
- T1801 (bug): Unescaped backslashes in config values cause configuration failure

### 3.3.728 2019-12-02

- T1840 (bug): PPPoE doesn't not rename `pppX` to `pppoeX`

### 3.3.729 2019-11-25

- T1824 (bug): Permission denied: `'/opt/vyatta/etc/config/vyos-migrate.log'`

### 3.3.730 2019-11-24

- T1673 (bug): vif bridge-group not migrated to bridge member interface
- T1799 (feature): Add support for GENEVE (Generic Network Virtualization Encapsulation)

### 3.3.731 2019-11-23

- T1627 (feature): Rewrite wireless interface in new style XML syntax

### 3.3.732 2019-11-21

- T1818 (default): Print name of migration script on failure
- T1814 (default): Add log of migration scripts run during config migration

### 3.3.733 2019-11-14

- T1710 (default): [equuleus] buster: add patch to fix live-build missing key error
- T1804 (default): Add python3-psutil to docker image
- T1736 (default): Decide on best practice for patching live-team packages for VyOS build system
- T1424 (default): Rewrite the config load script

### 3.3.734 2019-11-11

- T1793 (feature): Editing description on an interface causes BGP sessions to reset on commit

### 3.3.735 2019-11-10

- T1791 (feature): Update Linux Kernel to 4.19.82

### 3.3.736 2019-11-08

- T1789 (bug): ddclient not working with generated RFC2136 / nsupdate config

### 3.3.737 2019-11-03

- T1777 (bug): Bonding interface MAC address mismatch after reboot
- T1752 (bug): PPPoE does not automatically start on boot

### 3.3.738 2019-11-02

- T1783 (bug): Interface can't unpin from bridge

### 3.3.739 2019-10-22

- T1756 (feature): Modify output to be more useful - Wireguard

### 3.3.740 2019-10-21

- T1741 (feature): Add system wide proxy setting

### 3.3.741 2019-10-19

- [T1746](#) (bug): 201910180117 fails startup with 'Permission Denied' errors
- [T1743](#) (default): equuleus: remove references to SSH key type "rsa1" deprecated in Debian Buster

### 3.3.742 2019-10-18

- [T1712](#) (default): DHCP client sometimes doesn't start
- [T1604](#) (enhancement): equuleus: buster: vbash: tab completion breaks

### 3.3.743 2019-10-11

- [T1723](#) (bug): wireguard - Interface wg01 could not be brought up in time

### 3.3.744 2019-10-09

- [T1719](#) (feature): ssh deprecated options
- [T1718](#) (bug): ISO check in /opt/vyatta/sbin/install-image faulty
- [T1682](#) (feature): Migrate to new Jenkins Pipeline script

### 3.3.745 2019-10-08

- [T1717](#) (bug): disable multiple daemons to autostart at boot

### 3.3.746 2019-10-06

- [T1713](#) (feature): Remove deprecated packages no longer required after migration to Accel-PPP

### 3.3.747 2019-10-03

- [T1689](#) (feature): "reset openvpn" op-mode command should terminate and restart OpenVPN process

### 3.3.748 2019-10-01

- [T1706](#) (bug): wireguard broken in latest rolling

### 3.3.749 2019-09-30

- T1688 (feature): OpenVPN - Add new cipher aes-(128|192|256)-gcm

### 3.3.750 2019-09-28

- T1696 (bug): NTP - Tests fail when building vyos-1x
- T1512 (bug): vyos 1.2 openvpn client names with spaces created incorrectly

### 3.3.751 2019-09-27

- T1681 (feature): cleanup wireguard code since tagnodes are now visible
- T1695 (bug): Syntax error in interface-dummy.py

### 3.3.752 2019-09-26

- T1692 (bug): ipoe-server verify function error
- T1691 (bug): OpenVPN - Committing config when OpenVPN peer/server not available makes commit hang
- T1690 (feature): restart op-mode commands for 'service (pppoe|ipoe)-server'

### 3.3.753 2019-09-25

- T1672 (bug): Wireguard keys not automatically moved

### 3.3.754 2019-09-23

- T1679 (bug): during bootup: invalid literal for int() with base 10
- T1680 (feature): DHCP client does not release IP address on exit/deletion

### 3.3.755 2019-09-21

- T1676 (default): [equuleus] buster: update GRUB boot parameters during upgrade
- T1637 (feature): Rewrite ethernet interface in new style XML syntax
- T1675 (feature): OpenVPN - Specify minimum TLS version

### 3.3.756 2019-09-20

- [T1602](#) (default): equuleus: buster: add live build apt options for choosing vyos packages

### 3.3.757 2019-09-19

- [T1666](#) (feature): Deleting a bond will place member interfaces into A/D state

### 3.3.758 2019-09-17

- [T239](#) (bug): Improve documentation for the firewall all-ping setting

### 3.3.759 2019-09-16

- [T1040](#) (default): rc.local is executed too early

### 3.3.760 2019-09-15

- [T1662](#) (default): openvpn: 'show openvpn client' error
- [T1661](#) (default): openvpn: wrong checking for existence cert files
- [T1630](#) (bug): OpenVPN after changing it from root to nobody (unprivileged user) cant add routes

### 3.3.761 2019-09-13

- [T1660](#) (bug): Bonding dont't work on VyOS 1.2-rolling-201909120338
- [T1655](#) (enhancement): equuleus: buster: arm: vyos-accel-ppp build failes because of filename hardcoded as x86\_64 in debian/rules

### 3.3.762 2019-09-12

- [T1572](#) (feature): Wireguard keyPair per interface
- [T1545](#) (bug): IPSEC vti issue

### 3.3.763 2019-09-10

- [T1650](#) (feature): implement wireguard default key removal
- [T1649](#) (feature): feature documentation different keypairs per interface
- [T1648](#) (feature): add cli command 'delete wireguard named-key <key>'

### 3.3.764 2019-09-09

- T1639 (bug): wireguard pubkey change error

### 3.3.765 2019-09-07

- T1640 (feature): Update Linux Kernel to v4.19.70

### 3.3.766 2019-09-06

- T1624 (bug): Failed to set up config session
- T1636 (feature): Rewrite VXLAN in new style XML/Python
- T1479 (bug): libvyosconfig error reporting doesn't include line numbers
- T808 (feature): replace lighthttpd with nginx
- T1478 (bug): libvyosconfig parser does not support escaped quotes inside single-quoted strings

### 3.3.767 2019-09-04

- T1632 (bug): OpenVPN 'push' options with quotes
- T1631 (bug): Multiple push-route options cause error generating openvpn configuration
- T1557 (feature): Create generic abstraction for configuring interfaces e.g. IP address
- T1628 (feature): Adopt WireGuard configuration script to new vyos.ifconfig class
- T1614 (feature): Rewrite bonding interface in new style XML syntax

### 3.3.768 2019-09-02

- T1621 (default): Rewrite the rest of trivial vyatta-op commands to new syntax

### 3.3.769 2019-08-31

- T1456 (bug): Port group cannot be configured if the same port is configured as standalone and inside a range

### 3.3.770 2019-08-28

- T1615 (feature): After migration to pyroute2 the address DHCP statement is no longer covered

### 3.3.771 2019-08-27

- T1617 (default): OpenVPN push route failure
- T1250 (bug): FRR not setting default gateway from DHCP

### 3.3.772 2019-08-26

- T1591 (bug): OpenVPN "run show openvpn client status" does not work
- T1608 (feature): bridge: Bridge adding non existing interfaces is allowed but does not work
- T1548 (feature): Rewrite OpenVPN interface/op-commands in new style XML/Python
- T1607 (default): Convert 'reset conntrack' and 'reset ip[v6] cache' operations from vyatta-op to new syntax

### 3.3.773 2019-08-25

- T1611 (default): Migration to latest rolling fails with vyos.configtree.ConfigTreeError: Path [b'interfaces bridge br0 igmp-snooping querier'] doesn't exist

### 3.3.774 2019-08-23

- T1606 (bug): Rolling release no longer boots after adding hostname daemon

### 3.3.775 2019-08-21

- T1601 (feature): Rewrite loopback interface type with new style XML/Python interface
- T1596 (default): Convert 'telnet' and 'traceroute' vyatta-op commands to new syntax

### 3.3.776 2019-08-20

- T1595 (feature): Migrate deprecated "service dns forwarding listen-on" to listen-address

### 3.3.777 2019-08-19

- T1580 (feature): Rewrite dummy interface type with new style XML/Python interface
- T1590 (default): Convert 'show system' operations from vyatta-op to python/xml syntax

### 3.3.778 2019-08-17

- [T1592](#) (feature): Update Linux Kernel to v4.19.67

### 3.3.779 2019-08-15

- [T1584](#) (default): equuleus: buster: add consistent grub options for predictable interface names

### 3.3.780 2019-08-13

- [T1556](#) (feature): Rewrite Bridge in new style XML syntax

### 3.3.781 2019-08-09

- [T1569](#) (feature): interfaceconfig class documetation

### 3.3.782 2019-08-05

- [T1562](#) (feature): Change version scheme on current branch used for rolling releases

### 3.3.783 2019-08-04

- [T1561](#) (bug): VyOS rolling ISO cluttered with vyatta-ravpn Git Repo

### 3.3.784 2019-08-02

- [T853](#) (feature): Add SSTP server support
- [T742](#) (feature): Replace poptop and xl2tpd with accel-ppp

### 3.3.785 2019-08-01

- [T1544](#) (feature): L2TP documentation

### 3.3.786 2019-07-31

- [T1552](#) (feature): accel-ppp: SSTP documentation
- [T1553](#) (default): equuleus: buster: add 'noautologin' to boot parameters

### 3.3.787 2019-07-29

- T1532 (default): [equuleus] buster: GPG error on vyos package repository

### 3.3.788 2019-07-28

- T1547 (feature): accel-ppp/L2TP restructure CLI
- T1546 (bug): accel-ppp/L2TP radius-source address is not honored

### 3.3.789 2019-07-23

- T1533 (bug): Rolling builds broken!
- T1489 (feature): Add vlan\_mon usage at Accel

### 3.3.790 2019-07-22

- T1435 (enhancement): Make ip-address [OPTIONAL] (in dhcp-server -> static-mapping) to cope with "unfriendly" client-hostnames of IoT-Devices

### 3.3.791 2019-07-21

- T823 (feature): Rewrite DHCP op mode in the new style

### 3.3.792 2019-07-18

- T1497 (bug): "set system name-server" generates invalid/incorrect resolv.conf
- T533 (feature): Support for PPPoE MTU greater than 1492

### 3.3.793 2019-07-08

- T1510 (feature): [IPoE] vlan-mon option implementation
- T1508 (feature): [pppoe] migration script for service pppoe-server interface
- T1494 (feature): accel-ppp: IPoE update documentation
- T989 (feature): Add support for IPoE server

### 3.3.794 2019-07-03

- T1502 (feature): Add build sanity checking tools to the dev builds

### 3.3.795 2019-07-02

- T1099 (default): Openvpn: use config files instead of one long command.
- T1495 (feature): accel-ppp: IPoE implement IPv6 PD

### 3.3.796 2019-07-01

- T1498 (bug): Nameservers are not propagated into resolv.conf

### 3.3.797 2019-06-24

- T1482 (feature): Add OpenVPN SHA384 hashing algorithm

### 3.3.798 2019-06-23

- T1476 (bug): Update PowerDNS recursor to 4.2 series

### 3.3.799 2019-06-22

- T1313 (feature): Add support for reusable build flavours
- T1202 (bug): Add `hvinfo` to the packages directory

### 3.3.800 2019-06-20

- T1413 (enhancement): equuleus: buster: vyos-xe-guest-utilities is not installable and breaks live-build
- T1412 (enhancement): equuleus: buster: vyos-netplug is not installable and breaks live-build

### 3.3.801 2019-06-19

- T1334 (feature): Migration script runner rewrite
- T1327 (bug): Set the serial console speed to 115200 by default

### 3.3.802 2019-06-18

- T1451 (bug): Intel e1000e driver missing in latest rolling release

### 3.3.803 2019-06-17

- T1408 (feature): pppoe-server - implement local-ipv6 for pure IPv6 based deployments

### 3.3.804 2019-06-12

- T1397 (default): Rewrite the config merge script

### 3.3.805 2019-06-05

- T1426 (default): Update the script that checks conntrack hash-size on reboot

### 3.3.806 2019-06-03

- T1423 (default): When merging remote config files, create known\_hosts file if not present.

### 3.3.807 2019-05-28

- T1410 (feature): Upgrade Linux Kernel to 4.19.46

### 3.3.808 2019-05-26

- T1404 (feature): Update iproute2 package to 4.19

### 3.3.809 2019-05-24

- T1407 (bug): pppoe IPv6 PD documention by practical example

### 3.3.810 2019-05-23

- T1402 (feature): Update Linux Kernel to 4.19.45

### 3.3.811 2019-05-22

- T1399 (bug): accel-ppp kernel modules missing in rolling build 20190522
- T1393 (bug): pppoe IPv6 pool doesn't work

### 3.3.812 2019-05-21

- T592 (bug): lldpcli: unknown command from argument 1: `#`

### 3.3.813 2019-05-16

- T1267 (feature): FRR: Add interface name for static routes
- T1148 (bug): epa2 BGP peers initiate before config is fully loaded, routes leak.

### 3.3.814 2019-05-06

- T1368 (feature): Enable MPLS support in Linux Kernel

### 3.3.815 2019-05-04

- T1365 (bug): Cannot configure syslog on 1.2.0-rolling+201904260337

### 3.3.816 2019-04-29

- T1352 (feature): vyos-documentaion: accel-pppoe adding CIDR based IP pool option

### 3.3.817 2019-04-21

- T1348 (feature): Upgrade WireGuard to 0.0.20190406-1
- T1347 (feature): Upgrade Linux Kernel to 4.19.36

### 3.3.818 2019-04-20

- T1344 (feature): Unclutter "system login radius" configuration nodes

### 3.3.819 2019-04-19

- T1325 (default): GRE tunnel to Cisco router fails in 1.2.0 - works in 1.1.8

### 3.3.820 2019-04-16

- T1184 (feature): wireguard - extend documentation with the show interface wireguard commands

### 3.3.821 2019-04-15

- T1260 (feature): VICI-based implementation of "run show vpn ipsec sa"
- T1248 (default): Add a function for copying nodes to the vyos.configtree library

### 3.3.822 2019-04-05

- T1324 (feature): update documtation for 'set system login user level'

### 3.3.823 2019-04-04

- T1323 (feature): migrate operator accounts to admin accounts and remove the option to setup an operator account

### 3.3.824 2019-03-20

- T405 (feature): Add binaries for lcdproc

### 3.3.825 2019-03-12

- T1284 (feature): accel-ppp: pptp implementation documention
- T833 (feature): New PPTP server implementation based on accel-ppp

### 3.3.826 2019-02-22

- T1257 (bug): implement 'set system static-host-mapping' in host\_name.py and remove old function calls

### 3.3.827 2019-02-21

- T1214 (bug): Add `ipaddrcheck` to the packages directory

### 3.3.828 2019-02-10

- T1154 (default): use of local cache to build iso

### 3.3.829 2019-02-09

- T1236 (feature): Update Linux Kernel

## 3.4 1.2.6-S1

1.2.6-S1 is a security release made in September 2020.

### 3.4.1 Resolved issues

VyOS 1.2.6 release was found to be susceptible to CVE-2020-10995. It's a low- impact vulnerability in the PowerDNS recursor that allows an attacker to cause performance degradation via a specially crafted authoritative DNS server reply.

- T2899 remote syslog server migration error on update

## 3.5 1.2.6

1.2.6 is a maintenance release made in September 2020.

### 3.5.1 Resolved issues

- T103 DHCP server prepends shared network name to hostnames
- T125 Missing PPPoE interfaces in l2tp configuration
- T1194 cronjob is being setup even if not saved
- T1205 module pcspkr missing
- T1219 Redundant active-active configuration, asymmetric routing and conntrack-sync cache
- T1220 Show transceiver information from plugin modules, e.g SFP+, QSFP
- T1221 BGP - Default route injection is not processed by the specific route-map
- T1241 Remove of policy route throws CLI error
- T1291 Under certain conditions the VTI will stay forever down
- T1463 Missing command *show ip bgp scan* appears in command completion
- T1575 *show snmp mib ifmib* crashes with IndexError
- T1699 Default net.ipv6.route.max\_size 32768 is too low
- T1729 PIM (Protocol Independent Multicast) implementation
- T1901 Semicolon in values is interpreted as a part of the shell command by validators
- T1934 Change default hostname when deploy from OVA without params.
- T1938 syslog doesn't start automatically
- T1949 Multihop IPv6 BFD is unconfigurable
- T1953 DDNS service name validation rejects valid service names
- T1956 PPPoE server: support PADO-delay
- T1973 Allow route-map to match on BGP local preference value
- T1974 Allow route-map to set administrative distance
- T1982 Increase rotation for atop.acct

- T1983 Expose route-map when BGP routes are programmed in to FIB
- T1985 pppoe: Enable ipv6 modules without configured ipv6 pools
- T2000 strongSwan does not install routes to table 220 in certain cases
- T2021 OSPFv3 doesn't support decimal area syntax
- T2062 Wrong dhcp-server static route subnet bytes
- T2091 swanctl.conf file is not generated properly if more than one IPsec profile is used
- T2131 Improve syslog remote host CLI definition
- T2224 Update Linux Kernel to v4.19.114
- T2286 IPoE server vulnerability
- T2303 Unable to delete the image version that came from OVA
- T2305 Add release name to „show version“ command
- T2311 Statically configured name servers may not take precedence over ones from DHCP
- T2327 Unable to create syslog server entry with different port
- T2332 Backport node option for a syslog server
- T2342 Bridge l2tpv3 + ethX errors
- T2344 PPPoE server client static IP assignment silently fails
- T2385 salt-minion: improve completion helpers
- T2389 BGP community-list unknown command
- T2398 op-mode „dhcp client leases interface“ completion helper misses interfaces
- T2402 Live ISO should warn when configuring that changes won't persist
- T2443 NHRP: Add debugging information to syslog
- T2448 *monitor protocol bgp* subcommands fail with ,command incomplete‘
- T2458 Update FRR to 7.3.1
- T2476 Bond member description change leads to network outage
- T2478 login radius: use NAS-IP-Address if defined source address
- T2482 Update PowerDNS recursor to 4.3.1 for CVE-2020-10995
- T2517 vyos-container: link\_filter: No such file or directory
- T2526 Wake-On-Lan CLI implementation
- T2528 „update dns dynamic“ throws FileNotFoundError exception
- T2536 „show log dns forwarding“ still refers to dnsmasq
- T2538 Update Intel NIC drivers to recent release (preparation for Kernel >=5.4)
- T2545 Show physical device offloading capabilities for specified ethernet interface
- T2563 Wrong interface binding for Dell VEP 1445
- T2605 SNMP service is not disabled by default
- T2625 Provide generic Library for package builds
- T2686 FRR: BGP: large-community configuration is not applied properly after upgrading FRR to 7.3.x series

- T2701 *vpn ipsec pfs enable* doesn't work with IKE groups
- T2728 Protocol option ignored for IPSec peers in transport mode
- T2734 WireGuard: fwmark CLI definition is inconsistent
- T2757 „show system image version“ contains additional new-line character breaking output
- T2797 Update Linux Kernel to v4.19.139
- T2822 Update Linux Kernel to v4.19.141
- T2829 PPPoE server: mppe setting is implemented as node instead of leafNode
- T2831 Update Linux Kernel to v4.19.142
- T2852 rename dynamic dns interface breaks ddclient.cache permissions
- T2853 Intel QAT acceleration does not work

## 3.6 1.2.5

1.2.5 is a maintenance release made in April 2020.

### 3.6.1 Resolved issues

- T1020 OSPF Stops distributing default route after a while
- T1228 pppoe default-route force option not working (Rel 1.2.0-rc11)
- T1301 bgp peer-groups don't work when „no-ipv4-unicast“ is enabled.
- T1341 Adding rate-limiter for pppoe server users
- T1376 Incorrect DHCP lease counting
- T1392 Large firewall rulesets cause the system to lose configuration and crash at startup
- T1416 2 dhcp server run in failover mode can't sync hostname with each other
- T1452 accel-pppoe - add vendor option to shaper
- T1490 BGP configuration (is lost|not applied) when updating 1.1.8 -> 1.2.1
- T1780 Adding ipsec ike closeaction
- T1803 Unbind NTP while it's not requested...
- T1821 „authentication mode radius“ has no effect for PPPoE server
- T1827 Increase default gc\_thresh
- T1828 Missing completion helper for „set system syslog host 192.0.2.1 facility all protocol“
- T1832 radvd adding feature DNSSL branch.example.com example.com to existing package
- T1837 PPPoE unrecognized option ,replacedefaultroute‘
- T1851 wireguard - changing the pubkey on an existing peer seems to destroy the running config.
- T1858 l2tp: Delete deprecated outside-nexthop and add gateway-address
- T1864 Lower IPSec DPD timeout lower limit from 10s -> 2s
- T1879 Extend Dynamic DNS XML definition value help strings and validators

- T1881 Execute permissions are removed from custom SNMP scripts at commit time
- T1884 Keeping VRRP transition-script native behaviour and adding stop-script
- T1891 Router announcements broken on boot
- T1900 Enable SNMP for VRRP.
- T1902 Add redistribute non main table in bgp
- T1909 Incorrect behaviour of static routes with overlapping networks
- T1913 „system ipv6 blacklist“ command has no effect
- T1914 IPv6 multipath hash policy does not apply
- T1917 Update WireGuard to Debian release 0.0.20191219-1
- T1934 Change default hostname when deploy from OVA without params.
- T1935 NIC identification and usage problem in Hyper-V environments
- T1936 pppoe-server CLI control features
- T1964 SNMP Script-extensions allows names with spaces, but commit fails
- T1967 BGP parameter „enforce-first-as“ does not work anymore
- T1970 Correct adding interfaces on boot
- T1971 Missing modules in initrd.img for PXE boot
- T1998 Update FRR to 7.3
- T2001 Error when router reboot
- T2032 Monitor bandwidth bits
- T2059 Set source-validation on bond vif don't work
- T2066 PPPoE interface can be created multiple times - last wins
- T2069 PPPoE-client does not works with service-name option
- T2077 ISO build from crux branch is failing
- T2079 Update Linux Kernel to v4.19.106
- T2087 Add maxfail 0 option to pppoe configuration.
- T2100 BGP route advertisement with checks rib
- T2120 „reset vpn ipsec-peer“ doesn't work with named peers
- T2197 Cant add vif-s interface into a bridge
- T2228 WireGuard does not allow ports < 1024 to be used
- T2252 HTTP API add system image can return ,504 Gateway Time-out‘
- T2272 Set system flow-accounting disable-imt has syntax error
- T2276 PPPoE server vulnerability

## 3.7 1.2.4

1.2.4 is a maintenance release made in December 2019.

### 3.7.1 Resolved issues

- T258 Can not configure wan load-balancing on vyos-1.2
- T818 SNMP v3 - remove required engineid from user node
- T1030 Upgrade ddclient from 3.8.2 to 3.9. (support Cloudflare API v4)
- T1183 BFD Support via FRR
- T1299 Allow SNMPd to be extended with custom scripts
- T1351 accel-pppoe adding CIDR based IP pool option
- T1391 In route-map set community additive
- T1394 syslog systemd and host\_name.py race condition
- T1401 Copying files with the FTP protocol fails if the password contains special characters
- T1421 OpenVPN client push-route stopped working, needs added quotes to fix
- T1430 Add options for custom DHCP client-id and hostname
- T1447 Python subprocess called without import in host\_name.py
- T1470 improve output of „show dhcpv6 server leases“
- T1485 Enable ‚AdvIntervalOpt‘ option in for radvd.conf
- T1496 Separate rolling release and LTS kernel builds
- T1560 „set load-balancing wan rule 0“ causes segfault and prevent load balancing from starting
- T1568 strip-private command improvement for additional masking of IPv6 and MAC address
- T1578 completion offers „show table“, but show table does not exist
- T1593 Support ip6gre
- T1597 /usr/sbin/rsyslogd after deleting „system syslog“
- T1638 vyos-hostsd not setting system domain name
- T1678 hostfile-update missing line feed
- T1694 NTPd: Do not listen on all interfaces by default
- T1701 Delete domain-name and domain-search won't work
- T1705 High CPU usage by bgpd when snmp is active
- T1707 DHCP static mapping and exclude address not working
- T1708 Update Rolling Release Kernel to 4.19.76
- T1709 Update WireGuard to 0.0.20190913
- T1716 Update Intel NIC drivers to recent versions
- T1726 Update Linux Firmware binaries to a more recent version 2019-03-14 -> 2019-10-07
- T1728 Update Linux Kernel to 4.19.79

- T1737 SNMP tab completion missing
- T1738 Copy SNMP configuration from node to node raises exception
- T1740 Broken OSPFv2 virtual-link authentication
- T1742 NHRP unable to commit.
- T1745 dhcp-server commit fails with „DHCP range stop address must be greater or equal to the range start address y!“ when static mapping has same IP as range stop
- T1749 numeric validator doesn't support multiple ranges
- T1769 Remove complex SNMPv3 Transport Security Model (TSM)
- T1772 <regex> constraints in XML are partially broken
- T1778 Kilobits/Megabits difference in configuration Vynos/FRR
- T1780 Adding ipsec ike closeaction
- T1786 disable-dhcp-nameservers is missed in current host\_name.p implementation
- T1788 Intel QAT (QuickAssist Technology ) implementation
- T1792 Update WireGuard to Debian release 0.0.20191012-1
- T1800 Update Linux Kernel to v4.19.84
- T1809 Wireless: SSID scan does not work in AP mode
- T1811 Upgrade from 1.1.8: Config file migratio failed: module=l2tp
- T1812 DHCP: hostnames of clients not resolving afte update v1.2.3 -> 1.2-rolling
- T1819 Reboot kills SNMPv3 configuration
- T1822 Priority inversion wireless interface dhcpv6
- T1825 Improve DHCP configuration error message
- T1836 import-conf-mode-commands in vyos-1x/scripts fails to create an xml
- T1839 LLDP shows „VyOS unknown“ instead of „VyOS“
- T1841 PPP ipv6-up.d direcotry missing
- T1893 igmp-proxy: Do not allow adding unknown interface
- T1903 Implementation udev predefined interface naming
- T1904 update eth1 and eth2 link files for the vep4600

## 3.8 1.2.3

1.2.3 is a maintenance and feature backport release made in September 2019.

### 3.8.1 New features

- HTTP API
- T1524 „set service dns forwarding allow-from <IPv4 net|IPv6 net>“ option for limiting queries to specific client networks
- T1503 Functions for checking if a commit is in progress
- T1543 „set system config-mangement commit-archive source-address“ option
- T1554 Intel NIC drivers now support receive side scaling and multiqueue

### 3.8.2 Resolved issues

- T1209 OSPF max-metric values over 100 no longer causes commit errors
- T1333 Fixes issue with DNS forwarding not performing recursive lookups on domain specific forwarders
- T1362 Special characters in VRRP passwords are handled correctly
- T1377 BGP weight is applied properly
- T1420 Fixed permission for log files
- T1425 Wireguard interfaces now support /31 addresses
- T1428 Wireguard correctly handles firewall marks
- T1439 DHCPv6 static mappings now work correctly
- T1450 Flood ping commands now works correctly
- T1460 Op mode „show firewall“ commands now support counters longer than 8 digits (T1460)
- T1465 Fixed priority inversion in VTI commands
- T1468 Fixed remote-as check in the BGP route-reflector-client option
- T1472 It's now possible to re-create VRRP groups with RFC compatibility mode enabled
- T1527 Fixed a typo in DHCPv6 server help strings
- T1529 Unnumbered BGP peers now support VLAN interfaces
- T1530 Fixed „set system syslog global archive file“ command
- T1531 Multiple fixes in cluster configuration scripts
- T1537 Fixed missing help text for „service dns“
- T1541 Fixed input validation in DHCPv6 relay options
- T1551 It's now possible to create a QinQ interface and a firewall assigned to it in one commit
- T1559 URL filtering now uses correct rule database path and works again
- T1579 „show log vpn ipsec“ command works again
- T1576 „show arp interface <intf>“ command works again
- T1605 Fixed regression in L2TP/IPsec server
- T1613 Netflow/sFlow captures IPv6 traffic correctly
- T1616 „renew dhcpv6“ command now works from op mode
- T1642 BGP remove-private-as option iBGP vs eBGP check works correctly now

- T1540, T1360, T1264, T1623 Multiple improvements in name servers and hosts configuration handling

### 3.8.3 Internals

`/etc/resolv.conf` and `/etc/hosts` files are now managed by the `vyos-hostsd` service that listens on a ZMQ socket for update messages.

## 3.9 1.2.2

1.2.2 is a maintenance release made in July 2019.

### 3.9.1 New features

- Options for per-interface MSS clamping.
- BGP extended next-hop capability
- Relaxed BGP multipath option
- Internal and external options for „remote-as“ (accept any AS as long as it's the same to this router or different, respectively)
- „Unnumbered“ (interface-based) BGP peers
- BGP no-prepend option
- Additive BGP community option
- OSPFv3 network type option
- Custom arguments for VRRP scripts
- A script for querying values from config files

### 3.9.2 Resolved issues

- Linux kernel 4.19.54, including a fix for the TCP SACK vulnerability
- T1371 VRRP health-check scripts now can use arguments
- T1497 DNS server addresses coming from a DHCP server are now correctly propagated to `resolv.conf`
- T1469 Domain-specific name servers in DNS forwarding are now used for recursive queries
- T1433 `run show dhcpv6 server leases` now display leases correctly
- T1461 Deleting `firewall options` node no longer causes errors
- T1458 Correct hostname is sent to remote syslog again
- T1438 Board serial number from DMI is correctly displayed in `show version`
- T1358, T1355, T1294 Multiple corrections in remote syslog config
- T1255 Fixed missing newline in `/etc/hosts`
- T1174 `system domain-name` is correctly included in `/etc/resolv.conf`
- T1465 Fixed priority inversion in interfaces `vti vtiX ip` settings

- T1446 Fixed errors when installing with RAID1 on UEFI machines
- T1387 Fixed an error on disabling an interfaces that has no address
- T1367 Fixed deleting VLAN interface with non-default MTU
- T1505 `vyos.config return_effective_values()` function now correctly returns a list rather than a string

## 3.10 1.2.1

VyOS 1.2.1 is a maintenance release made in April 2019.

### 3.10.1 Resolved issues

- Package updates: kernel 4.19.32, open-vm-tools 10.3, latest Intel NIC drivers
- T1326 The kernel now includes drivers for various USB serial adapters, which allows people to add a serial console to a machine without onboard RS232, or connect to something else from the router
- The collection of network card firmware is now much more extensive
- T1271 VRRP now correctly uses a virtual rather than physical MAC addresses in the RFC-compliant mode
- T1330 DHCP WPAD URL option works correctly again
- T1312 Many to many NAT rules now can use source/destination and translation networks of non-matching size. If 1:1 network bits translation is desired, it's now users responsibility to check if prefix length matches.
- T1290 IPv6 network prefix translation is fixed
- T1308 Non-alphanumeric characters such as > can now be safely used in PPPoE passwords
- T1305 `show | commands` no longer fails when a config section ends with a leaf node such as `timezone` in `show system | commands`
- T1235 `show | commands` correctly works in config mode now
- T1298 VTI is now compatible with the DHCP-interface IPsec option
- T1277 `show dhcp server statistics` command was broken in latest Crux
- T1261 An issue with TFTP server refusing to listen on addresses other than loopback was fixed
- T1224 Template issue that might cause UDP broadcast relay fail to start is fixed
- T1067 VXLAN value validation is improved
- T1211 Blank hostnames in DHCP updates no longer can crash DNS forwarding
- T1322 Correct configuration is now generated for DHCPv6 relays with more than one upstream interface
- T1234 `relay-agents-packets` option works correctly now
- T1231 Dynamic DNS data is now cleaned on configuration change
- T1282 Remote Syslog can now use a fully qualified domain name
- T1279 ACPI power off works again
- T1247 Negation in WAN load balancing rules works again
- T1218 FRR staticd now starts on boot correctly
- T1296 The installer now correctly detects SD card devices

- [T1225](#) Wireguard peers can be disabled now
- [T1217](#) The issue with Wireguard interfaces impossible to delete is fixed
- [T1160](#) Unintended IPv6 access is fixed in SNMP configuration
- [T1060](#) It's now possible to exclude hosts from the transparent web proxy
- [T484](#) An issue with rules impossible to delete from the zone-based firewall is fixed

---

## Installation and Image Management

---

### 4.1 Installation

VyOS installation requires a downloaded VyOS .iso file. That file is a live install image that lets you boot a live VyOS. From the live system, you can proceed to a permanent installation on a hard drive or any other type of storage.

Tab. 1: Comparison of VyOS image releases

Re- lea- se Type	Description	Re- lease Cycle	Intended Use	Access Images	to	Ac- cess to Sour- ce
<b>Night-ly (Current)</b>	Automatically built from the current branch. Always up to date with cutting edge development but guaranteed to contain bugs.	Every night	Developing VyOS, testing new features, experimenting.	Everyone		Eve-ryone
<b>Night-ly (Beta)</b>	Automatically built from the development branch and released alongside snapshots. Most likely contains bugs.	Every night	Developing and testing the latest major version under development.	Everyone		Eve-ryone
<b>Snap-shot</b>	A particularly stable release frozen from nightly each month after manual testing. Still contains experimental code.	Every month until RC comes out	Home labs and simple networks that call for new features.	Everyone		Eve-ryone
<b>Re-lease Can-didate</b>	Rather stable. All development focuses on testing and hunting down remaining bugs following the feature freeze.	Irregu-larly until EPA comes out	Labs, small offices and non-critical production systems backed by a high-availability setup.	Everyone		Eve-ryone
<b>Ear-ly Pro-duc-tion Ac-cess</b>	Highly stable with no known bugs. Needs to be tested repeatedly under different conditions before it can become the final release.	Irregu-larly until LTS comes out	Non-critical production environments, preparing for the LTS release.	Everyone		Eve-ryone
<b>Long-Term Sup-port</b>	Guaranteed to be stable and carefully maintained for several years after the release. No features are introduced but security updates are released in a timely manner.	Every major version	Large-scale enterprise networks, internet service providers, critical production environments that call for minimum downtime.	Subscribers, contributors, non-profits, emergency services, academic institutions		Eve-ryone

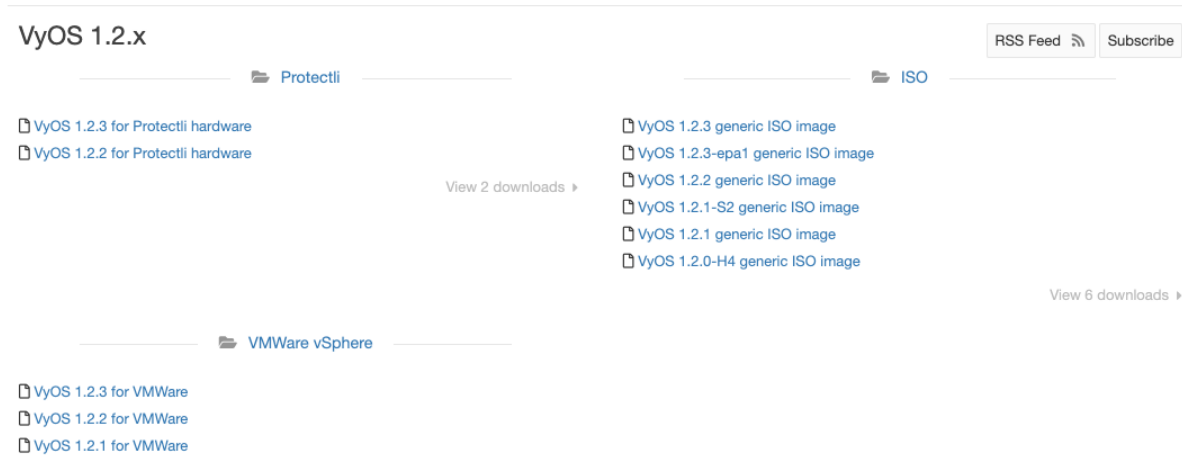

### 4.1.1 Hardware requirements

The minimum system requirements are 1024 MiB RAM and 2 GiB storage. Depending on your use, you might need additional RAM and CPU resources e.g. when having multiple BGP full tables in your system.

### 4.1.2 Download

#### Registered Subscribers

Registered subscribers can log into <https://support.vyos.io/> to access a variety of different downloads via the „Downloads“ link. These downloads include LTS (Long-Term Support), the associated hot-fix releases, early public access releases, pre-built VM images, as well as device specific installation ISOs.

#### Building from source

Non-subscribers can always get the LTS release by building it from source. Instructions can be found in the *VyOS erstellen* section of this manual. VyOS source code repository is available for everyone at <https://github.com/vyos/vyos-build>.

#### Rolling Release

Everyone can download bleeding-edge VyOS rolling images from: <https://downloads.vyos.io/>

**Bemerkung:** Rolling releases contain all the latest enhancements and fixes. This means that there will be new bugs of course. If you think you hit a bug please follow the guide at *Fehlerbericht/Ereignis*. We depend on your feedback to improve VyOS!

The following link will always fetch the most recent VyOS build for AMD64 systems from the current branch: <https://downloads.vyos.io/rolling/current/amd64/vyos-rolling-latest.iso>

## Download Verification

LTS images are signed by the VyOS lead package-maintainer private key. With the official public key, the authenticity of the package can be verified. GPG (GNU Privacy Guard) is used for verification.

**Bemerkung:** This subsection only applies to LTS images, for Rolling images please jump to [Live installation](#).

## Preparing for the verification

First, install GPG or another OpenPGP implementation. On most GNU+Linux distributions it is installed by default as package managers use it to verify package signatures. If not pre-installed, it will need to be downloaded and installed.

The official VyOS public key can be retrieved in a number of ways. Skip to [GPG verification](#) if the key is already present.

It can be retrieved directly from a key server:

```
gpg --recv-keys FD220285A0FE6D7E
```

Or it can be accessed via a web browser:

<https://pgp.mit.edu/pks/lookup?op=get&search=0xFD220285A0FE6D7E>

Or from the following block:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----

8vzPzaWHhkOkU8/J/Ci7+vNtU0Zb
=Ld8S
-----END PGP PUBLIC KEY BLOCK-----
```

Store the key in a new text file and import it into GPG via: `gpg --import file_with_the_public_key`

The import can be verified with:

```
$ gpg --list-keys
...
pub   rsa4096 2015-08-12 [SC]
       0694A9230F5139BF834BA458FD220285A0FE6D7E
uid    [ unknown] VyOS Maintainers (VyOS Release) <maintainers@vyos.net>
sub    rsa4096 2015-08-12 [E]
```

## GPG verification

With the public key imported, the signature for the desired image needs to be downloaded.

**Bemerkung:** The signature can be downloaded by appending `.asc` to the URL of the downloaded VyOS image. That small `.asc` file is the signature for the associated image.

Finally, verify the authenticity of the downloaded image:

```
$ gpg2 --verify vyos-1.2.1-amd64.iso.asc vyos-1.2.1-amd64.iso
gpg: Signature made So 14 Apr 12:58:07 2019 CEST
gpg:          using RSA key FD220285A0FE6D7E
gpg: Good signature from "VyOS Maintainers (VyOS Release) <maintainers@vyos.net>"
↳ [unknown]
Primary key fingerprint: 0694 A923 0F51 39BF 834B A458 FD22 0285 A0FE 6D7E
```

## Minisign verification

Currently we are using GPG for release signing (pretty much like everyone else).

Popularity of GPG for release signing comes from the fact that many people already had it installed for email encryption/signing. Inside a VyOS image, signature checking is the only reason to have it installed. However, it still comes with all the features no one needs, such as support for multiple outdated cipher suits and ability to embed a photo in the key file. More importantly, web of trust, the basic premise of PGP, is never used in release signing context. Once you have a knowingly authentic image, authenticity of upgrades is checked using a key that comes in the image, and to get their first image people never rely on key servers either.

Another point is that we are using RSA now, which requires absurdly large keys to be secure.

In 2015, OpenBSD introduced signify. An alternative implementation of the same protocol is minisign, which is also available for Windows and macOS, and in most GNU/Linux distros it's in the repositories now.

Its installed size (complete with libsodium) is less than that of GPG binary alone (not including libgcrypt and some other libs, which I think we only use for GPG). Since it uses elliptic curves, it gets away with much smaller keys, and it doesn't include as much metadata to begin with.

Another issue of GPG is that it creates a `/root/.gnupg` directory just for release checking. The dir is small so the fact that it's never used again is an aesthetic problem, but we've had that process fail in the past. But, small key size of the Ed25519 algorithm allows passing public keys in command line arguments, so verification process can be completely stateless:

T2108 switched the validation system to prefer minisign over GPG keys.

To verify a VyOS image starting off with VyOS 1.3.0-rc6 you can run:

```
$ minisign -V -P RWTR1ty930yontk6caB9WqmiQC4fgeyd/ejgRxCRGd2MQej7nqebHneP -m vyos-1.3.0-rc6-amd64.iso
vyos-1.3.0-rc6-amd64.iso.minisig
Signature and comment signature verified
Trusted comment: timestamp:1629997936 file:vyos-1.3.0-rc6-amd64.iso
```

During an image upgrade VyOS performs the following command:

```
$ minisign -V -p /usr/share/vyos/keys/vyos-release.minisign.pub -m vyos-1.3.0-rc6-amd64.iso
vyos-1.3.0-rc6-amd64.iso.minisig
Signature and comment signature verified
Trusted comment: timestamp:1629997936 file:vyos-1.3.0-rc6-amd64.iso
```

### 4.1.3 Live installation

---

**Bemerkung:** A permanent VyOS installation always requires to go first through a live installation.

---

VyOS, as other GNU+Linux distributions, can be tested without installing it in your hard drive. **With your downloaded VyOS .iso file you can create a bootable USB drive that will let you boot into a fully functional VyOS system.** Once you have tested it, you can either decide to begin a *Permanent installation* in your hard drive or power your system off, remove the USB drive, and leave everything as it was.

If you have a GNU+Linux system, you can create your VyOS bootable USB stick with the `dd` command:

1. Open your terminal emulator.
2. Find out the device name of your USB drive (you can use the `lsblk` command)

3. Unmount the USB drive. Replace X in the example below with the letter of your device and keep the asterisk (wildcard) to unmount all partitions.

```
$ umount /dev/sdX*
```

4. Write the image (your VyOS .iso file) to the USB drive. Note that here you want to use the device name (e.g. /dev/sdb), not the partition name (e.g. /dev/sdb1).

**Warning:** This will destroy all data on the USB drive!

```
# dd if=/path/to/vyos.iso of=/dev/sdX bs=8M; sync
```

5. Wait until you get the outcome (bytes copied). Be patient, in some computers it might take more than one minute.
6. Once dd has finished, pull the USB drive out and plug it into the powered-off computer where you want to install (or test) VyOS.
7. Power the computer on, making sure it boots from the USB drive (you might need to select booting device or change booting settings).
8. Once VyOS is completely loaded, enter the default credentials (login: vyos, password: vyos).

If you find difficulties with this method, prefer to use a GUI program, or have a different operating system, there are other programs you can use to create a bootable USB drive, like [balenaEtcher](#) (for GNU/Linux, macOS and Windows), [Rufus](#) (for Windows) and [many others](#). You can follow their instructions to create a bootable USB drive from an .iso file.

---

**Hinweis:** The default username and password for the live system is `vyos`.

---

#### 4.1.4 Permanent installation

---

**Bemerkung:** Before a permanent installation, VyOS requires a *Live installation*.

---

Unlike general purpose Linux distributions, VyOS uses „image installation“ that mimics the user experience of traditional hardware routers and allows keeping multiple VyOS versions installed simultaneously. This makes it possible to switch to a previous version if something breaks or miss-behaves after an image upgrade.

Every version is contained in its own squashfs image that is mounted in a union filesystem together with a directory for mutable data such as configurations, keys, or custom scripts.

---

**Bemerkung:** Older versions (prior to VyOS 1.1) used to support non-image installation (`install system` command). Support for this has been removed from VyOS 1.2 and newer releases. Older releases can still be upgraded via the general `add system image <image_path> upgrade` command (consult [Image Management](#) for further information).

---

In order to proceed with a permanent installation:

1. Log into the VyOS live system (use the default credentials: `vyos`, `vyos`)
2. Run the `install image` command and follow the wizard:

```

vyos@vyos:~$ install image
Welcome to the VyOS install program. This script
will walk you through the process of installing the
VyOS image to a local hard drive.
Would you like to continue? (Yes/No) [Yes]: Yes
Probing drives: OK
Looking for pre-existing RAID groups...none found.
The VyOS image will require a minimum 2000MB root.
Would you like me to try to partition a drive automatically
or would you rather partition it manually with parted? If
you have already setup your partitions, you may skip this step

Partition (Auto/Parted/Skip) [Auto]:

I found the following drives on your system:
sda    4294MB

Install the image on? [sda]:

This will destroy all data on /dev/sda.
Continue? (Yes/No) [No]: Yes

How big of a root partition should I create? (2000MB - 4294MB) [4294]MB:

Creating filesystem on /dev/sda1: OK
Done!
Mounting /dev/sda1...
What would you like to name this image? [1.2.0-rolling+201809210337]:
OK. This image will be named: 1.2.0-rolling+201809210337
Copying squashfs image...
Copying kernel and initrd images...
Done!
I found the following configuration files:
/opt/vyatta/etc/config.boot.default
Which one should I copy to sda? [/opt/vyatta/etc/config.boot.default]:

Copying /opt/vyatta/etc/config.boot.default to sda.
Enter password for administrator account
Enter password for user 'vyos':
Retype password for user 'vyos':
I need to install the GRUB boot loader.
I found the following drives on your system:
sda    4294MB

Which drive should GRUB modify the boot partition on? [sda]:

Setting up grub: OK
Done!

```

3. After the installation is completed, remove the live USB stick or CD.
4. Reboot the system.

```
vyos@vyos:~$ reboot
Proceed with reboot? (Yes/No) [No] Yes
```

You will boot now into a permanent VyOS system.

### 4.1.5 PXE Boot

VyOS can also be installed through PXE. This is a more complex installation method that allows deploying VyOS through the network.

#### Requirements

- Clients (where VyOS is to be installed) with a PXE-enabled NIC
- *DHCP Server*
- *TFTP Server*
- Webserver (HTTP) - optional, but we will use it to speed up installation
- VyOS ISO image to be installed (do not use images prior to VyOS 1.2.3)
- Files *pxelinux.0* and *ldlinux.c32* from the [Syslinux](#) distribution

#### Configuration

##### Step 1: DHCP

Configure a DHCP server to provide the client with:

- An IP address
- The TFTP server address (DHCP option 66). Sometimes referred as *boot server*
- The *bootfile name* (DHCP option 67), which is *pxelinux.0*

In this example we configured an existent VyOS as the DHCP server:

```
vyos@vyos# show service dhcp-server
shared-network-name mydhcp {
  subnet 192.168.1.0/24 {
    option {
      bootfile-name pxelinux.0
      bootfile-server 192.168.1.50
      default-router 192.168.1.50
    }
    range 0 {
      start 192.168.1.70
      stop 192.168.1.100
    }
    subnet-id 1
  }
}
```

## Step 2: TFTP

Configure a TFTP server so that it serves the following:

- The *pxelinux.0* file from the Syslinux distribution
- The *ldlinux.c32* file from the Syslinux distribution
- The kernel of the VyOS software you want to deploy. That is the *vmlinuz* file inside the */live* directory of the extracted contents from the ISO file.
- The initial ramdisk of the VyOS ISO you want to deploy. That is the *initrd.img* file inside the */live* directory of the extracted contents from the ISO file. Do not use an empty (0 bytes) *initrd.img* file you might find, the correct file may have a longer name.
- A directory named *pxelinux.cfg* which must contain the configuration file. We will use the [configuration](#) file shown below, which we named *default*.

In the example we configured our existent VyOS as the TFTP server too:

```
vyos@vyos# show service tftp-server
directory /config/tftpboot
listen-address 192.168.1.50
```

Example of the contents of the TFTP server:

```
vyos@vyos# ls -hal /config/tftpboot/
total 29M
drwxr-sr-x 3 tftp tftp      4.0K Oct 14 00:23 .
drwxrwsr-x 9 root vyattacfg 4.0K Oct 18 00:05 ..
-r--r--r-- 1 root vyattacfg 25M Oct 13 23:24 initrd.img-4.19.54-amd64-vyos
-rwxr-xr-x 1 root vyattacfg 120K Oct 13 23:44 ldlinux.c32
-rw-r--r-- 1 root vyattacfg 46K Oct 13 23:24 pxelinux.0
drwxr-xr-x 2 root vyattacfg 4.0K Oct 14 01:10 pxelinux.cfg
-r--r--r-- 1 root vyattacfg 3.7M Oct 13 23:24 vmlinuz

vyos@vyos# ls -hal /config/tftpboot/pxelinux.cfg
total 12K
drwxr-xr-x 2 root vyattacfg 4.0K Oct 14 01:10 .
drwxr-sr-x 3 tftp tftp      4.0K Oct 14 00:23 ..
-rw-r--r-- 1 root root      191 Oct 14 01:10 default
```

Example of simple (no menu) configuration file:

```
vyos@vyos# cat /config/tftpboot/pxelinux.cfg/default
DEFAULT VyOS123

LABEL VyOS123
  KERNEL vmlinuz
  APPEND initrd=initrd.img-4.19.54-amd64-vyos boot=live nopersistence noautologin_
  ↪nonetworking fetch=http://address:8000/filesystem.squashfs
```

### Step 3: HTTP

We also need to provide the *filesystem.squashfs* file. That is a heavy file and TFTP is slow, so you could send it through HTTP to speed up the transfer. That is how it is done in our example, you can find that in the configuration file above.

**First** run a web server - you can use a simple one like [Python's SimpleHTTPServer](#) and start serving the *filesystem.squashfs* file. The file can be found inside the */live* directory of the extracted contents of the ISO file.

**Second**, edit the configuration file of the [Step 2: TFTP](#) so that it shows the correct URL at `fetch=http://<address_of_your_HTTP_server>/filesystem.squashfs`.

---

**Bemerkung:** Do not change the name of the *filesystem.squashfs* file. If you are working with different versions, you can create different directories instead.

---

And **third**, restart the TFTP service. If you are using VyOS as your TFTP Server, you can restart the service with `sudo service tftpd-hpa restart`.

---

**Bemerkung:** Make sure the available directories and files in both TFTP and HTTP server have the right permissions to be accessed from the booting clients.

---

### Client Boot

Finally, turn on your PXE-enabled client or clients. They will automatically get an IP address from the DHCP server and start booting into VyOS live from the files automatically taken from the TFTP and HTTP servers.

Once finished you will be able to proceed with the `install image` command as in a regular VyOS installation.

## 4.1.6 Known Issues

This is a list of known issues that can arise during installation.

### Black screen on install

GRUB attempts to redirect all output to a serial port for ease of installation on headless hosts. This appears to cause an hard lockup on some hardware that lacks a serial port, with the result being a black screen after selecting the *Live system* option from the installation image.

The workaround is to type *e* when the boot menu appears and edit the GRUB boot options. Specifically, remove the:

```
console=ttyS0,115200
```

option, and type CTRL-X to boot.

Installation can then continue as outlined above.

## 4.2 Running VyOS in Virtual Environments

### 4.2.1 Running on Libvirt Qemu/KVM

Libvirt is an open-source API, daemon and management tool for managing platform virtualization. There are several ways to deploy VyOS on libvirt kvm. Use Virt-manager and native CLI. In an example we will be use use 4 gigabytes of memory, 2 cores CPU and default network virbr0.

#### CLI

##### Deploy from ISO

Create VM name vyos\_r1. You must specify the path to the ISO image, the disk qcow2 will be created automatically. The default network is the virtual network (type Virtio) created by the hypervisor with NAT.

```
$ virt-install -n vyos_r1 \
  --ram 4096 \
  --vcpus 2 \
  --cdrom /var/lib/libvirt/images/vyos.iso \
  --os-variant debian10 \
  --network network=default \
  --graphics vnc \
  --hvm \
  --virt-type kvm \
  --disk path=/var/lib/libvirt/images/vyos_r1.qcow2,bus=virtio,size=8 \
  --noautoconsole
```

Connect to VM with command `virsh console vyos_r1`

```
$ virsh console vyos_r1

Connected to domain vyos_r1
Escape character is ^]

vyos login: vyos
Password:

vyos@vyos:~$ install image
```

After installation - exit from the console using the key combination `Ctrl + ]` and reboot the system.

##### Deploy from qcow2

The convenience of using KVM (Kernel-based Virtual Machine) images is that they don't need to be installed. Download predefined VyOS.qcow2 image for KVM

```
curl --url link_to_vyos_kvm.qcow2 --output /var/lib/libvirt/images/vyos_kvm.qcow2
```

Create VM with `import qcow2` disk option.

```
$ virt-install -n vyos_r2 \  
  --ram 4096 \  
  --vcpus 2 \  
  --os-variant debian10 \  
  --network network=default \  
  --graphics vnc \  
  --hvm \  
  --virt-type kvm \  
  --disk path=/var/lib/libvirt/images/vyos_kvm.qcow2,bus=virtio \  
  --import \  
  --noautoconsole
```

Connect to VM with command `virsh console vyos_r2`

```
$ virsh console vyos_r2  
  
Connected to domain vyos_r2  
Escape character is ^]  
  
vyos login: vyos  
Password:  
  
vyos@vyos:~$
```

If you can not go to this screen

```
vyos login: vyos  
Password:
```

Stayed in this stage. This is because the KVM console is chosen as the default boot option.

```
Connected to domain vyos_r2  
Escape character is ^]
```

Open a secondary/parallel session and use this command to reboot the VM:

```
$ virsh reboot vyos_r2
```

Then go to the first session where you opened the console. Select VyOS 1.4.x for QEMU (Serial console) and press Enter

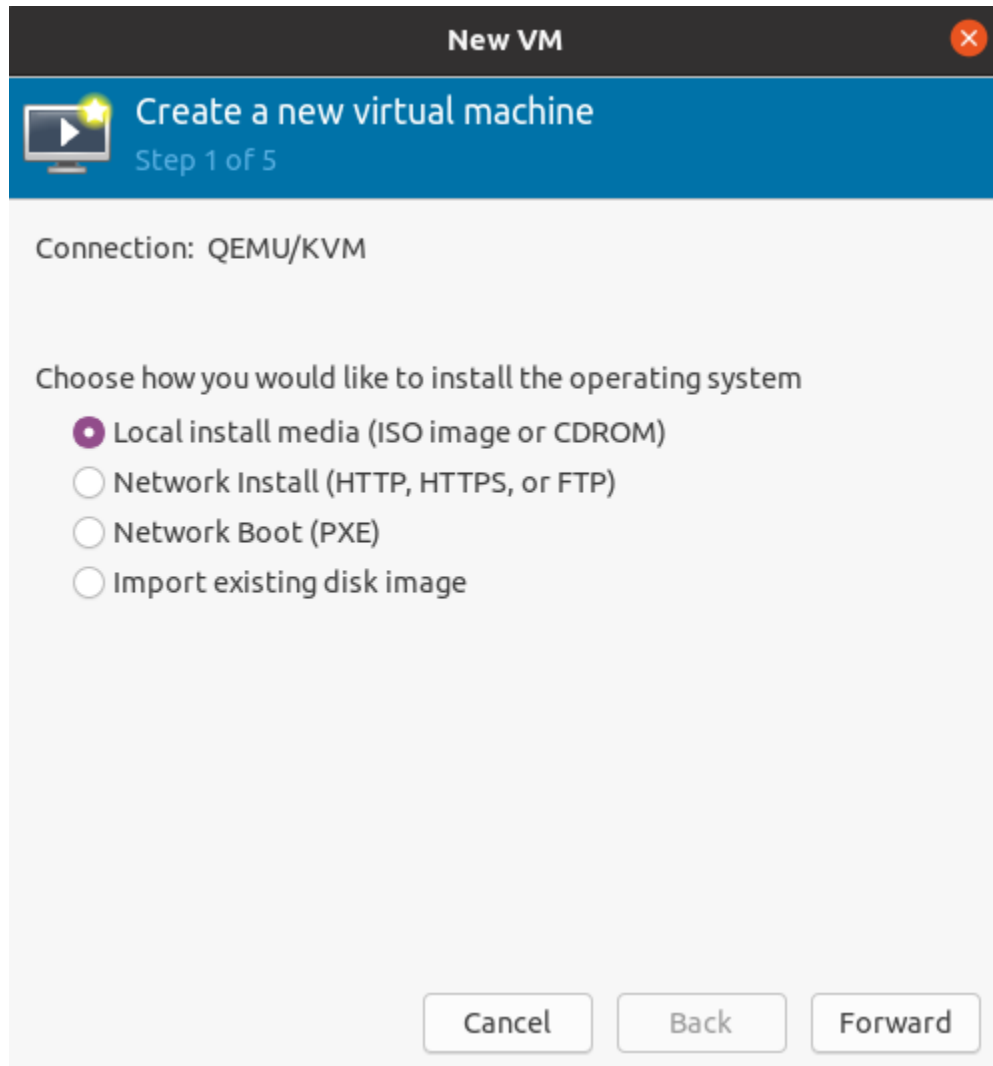

The system is fully operational.

## Virt-manager

The virt-manager application is a desktop user interface for managing virtual machines through libvirt. On the linux open VMM (Virtual Machine Manager).

## Deploy from ISO

1. Open VMM and Create a new VM (Virtual Machine)
2. Choose Local install media (ISO)

3. Choose path to iso vyos.iso. Operating System can be any Debian based.
4. Choose Memory and CPU
5. Disk size
6. Name of VM and network selection
7. Then you will be taken to the console.

New VM

Create a new virtual machine  
Step 2 of 5

Choose ISO or CDROM install media:

/home/Downloads/ISO/vyos-rolling-latest.iso

## 4.2.2 Running on Proxmox

Proxmox is an open-source platform for virtualization. Please visit <https://vyos.io> to see how to get a qcow2 image that can be imported into Proxmox.

### Deploy VyOS from CLI with qcow2 image

1. Copy the qcow2 image to a temporary directory on the Proxmox server.
2. The commands below assume that virtual machine ID 200 is unused and that the user wants the disk stored in a storage pool called *local-lvm*.

```
$ qm create 200 --name vyos2 --memory 2048 --net0 virtio,bridge=vmbr0
$ qm importdisk 200 /path/to/image/vyos-1.2.8-proxmox-2G.qcow2 local-lvm
$ qm set 200 --virtio0 local-lvm:vm-200-disk-0
$ qm set 200 --boot order=virtio0
```

3. Optionally, the user can attach a CDROM with an ISO as a cloud-init data source. The below command assumes the ISO has been uploaded to the *local* storage pool with the name *seed.iso*.

```
$ qm set 200 --ide2 media=cdrom,file=local:iso/seed.iso
```

4. Start the virtual machine in the proxmox GUI or CLI using `qm start 200`.

### Deploy VyOS from CLI with rolling release ISO

1. Download the rolling release iso from <https://vyos.net/get/nightly-builds/>. Non-subscribers can always get the LTS release by building it from source. Instructions can be found in the *VyOS erstellen* section of this manual. VyOS source code repository is available <https://github.com/vyos/vyos-build>.
2. Prepare VM for installation from ISO media. The commands below assume that your iso is available in a storage pool *local*, that you want it to have a VM ID *200* and want to create a new disk on storage pool *local-lvm* of size 15GB.

```
qm create 200 --name vyos --memory 2048 --net0 virtio,bridge=vmbr0 --ide2 media=cdrom,
↪file=local:iso/live-image-amd64.hybrid.iso --virtio0 local-lvm:15
```

3. Start the VM using the command `qm start 200` or using the start button located in the proxmox GUI.
4. Using the proxmox webGUI, open the virtual console for your newly created vm. Login username/password is *vyos/vyos*.
5. Once booted into the live system, type `install image` into the command line and follow the prompts to install VyOS to the virtual drive.
6. After installation has completed, remove the installation iso using the GUI or `qm set 200 --ide2 none`.
7. Reboot the virtual machine using the GUI or `qm reboot 200`.

Visit <https://www.proxmox.com/en/> for more information about the download and installation of this hypervisor.

## 4.2.3 Running on VMware ESXi

### ESXi 5.5 or later

.ova files are available for supporting users, and a VyOS can also be stood up using a generic Linux instance, and attaching the bootable ISO file and installing from the ISO using the normal process around *install image*.

---

**Bemerkung:** There have been previous documented issues with GRE/IPSEC tunneling using the E1000 adapter on the VyOS guest, and use of the VMXNET3 has been advised.

---

### Memory Contention Considerations

When the underlying ESXi host is approaching ~92% memory utilisation it will start the balloon process in a ,soft‘ state to start reclaiming memory from guest operating systems. This causes an artificial pressure using the vmmemctl driver on memory usage on the virtual guest. As VyOS by default does not have a swap file, this vmmemctl pressure is unable to force processes to move in memory data to the paging file, and blindly consumes memory forcing the virtual guest into a low memory state with no way to escape. The balloon can expand to 65% of guest allocated memory, so a VyOS guest running >35% of memory usage, can encounter an out of memory situation, and trigger the kernel oom\_kill process. At this point a weighted lottery favouring memory hungry processes will be run with the unlucky winner being terminated by the kernel.

It is advised that VyOS routers are configured in a resource group with adequate memory reservations so that ballooning is not inflicted on virtual VyOS guests.

### References

<https://muralidba.blogspot.com/2018/03/how-does-linux-out-of-memory-oom-killer.html>

## 4.2.4 Running on GNS3

Sometimes you may want to test VyOS in a lab environment. [GNS3](#) is a network emulation software you might use for it.

This guide will provide the necessary steps for installing and setting up VyOS on GNS3.

### Requirements

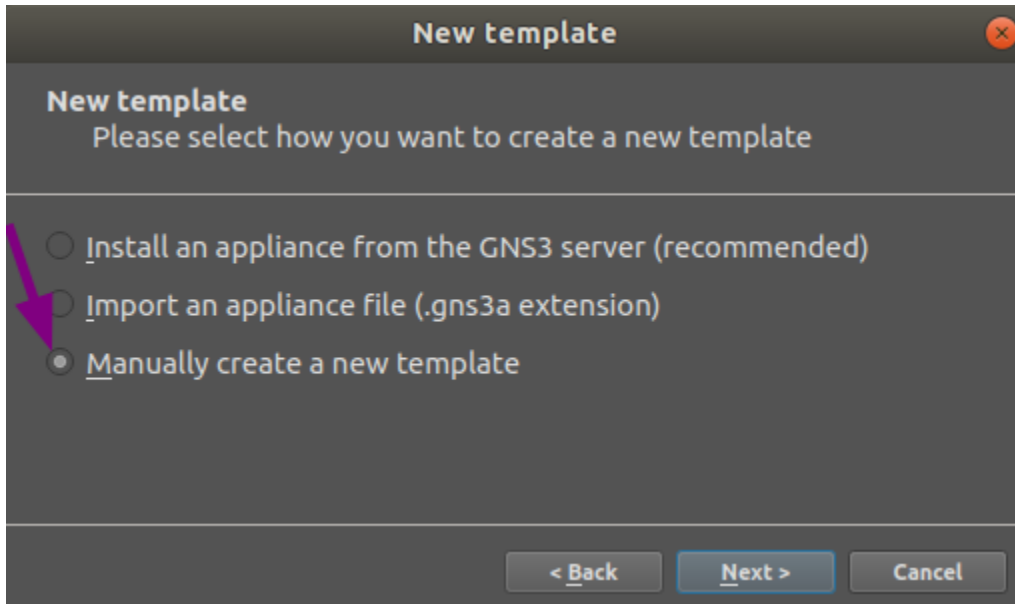

The following items are required:

- A VyOS installation image (.iso file). You can find how to get it on the [Installation](#) page
- A working GNS3 installation. For further information see the [GNS3 documentation](#).

## VM setup

First, a virtual machine (VM) for the VyOS installation must be created in GNS3.

Go to the GNS3 **File** menu, click **New template** and choose select **Manually create a new Template**.

Select **Qemu VMs** and then click on the **New** button.

Write a name for your VM, for instance „VyOS“, and click **Next**.

Select **qemu-system-x86\_64** as Qemu binary, then **512MB** of RAM and click **Next**.

Select **telnet** as your console type and click **Next**.

Select **New image** for the base disk image of your VM and click **Create**.

Use the defaults in the **Binary and format** window and click **Next**.

Use the defaults in the **Qcow2 options** window and click **Next**.

Set the disk size to 2000 MiB, and click **Finish** to end the **Qemu image creator**.

Click **Finish** to end the **New QEMU VM template** wizard.

Now the VM settings have to be edited.

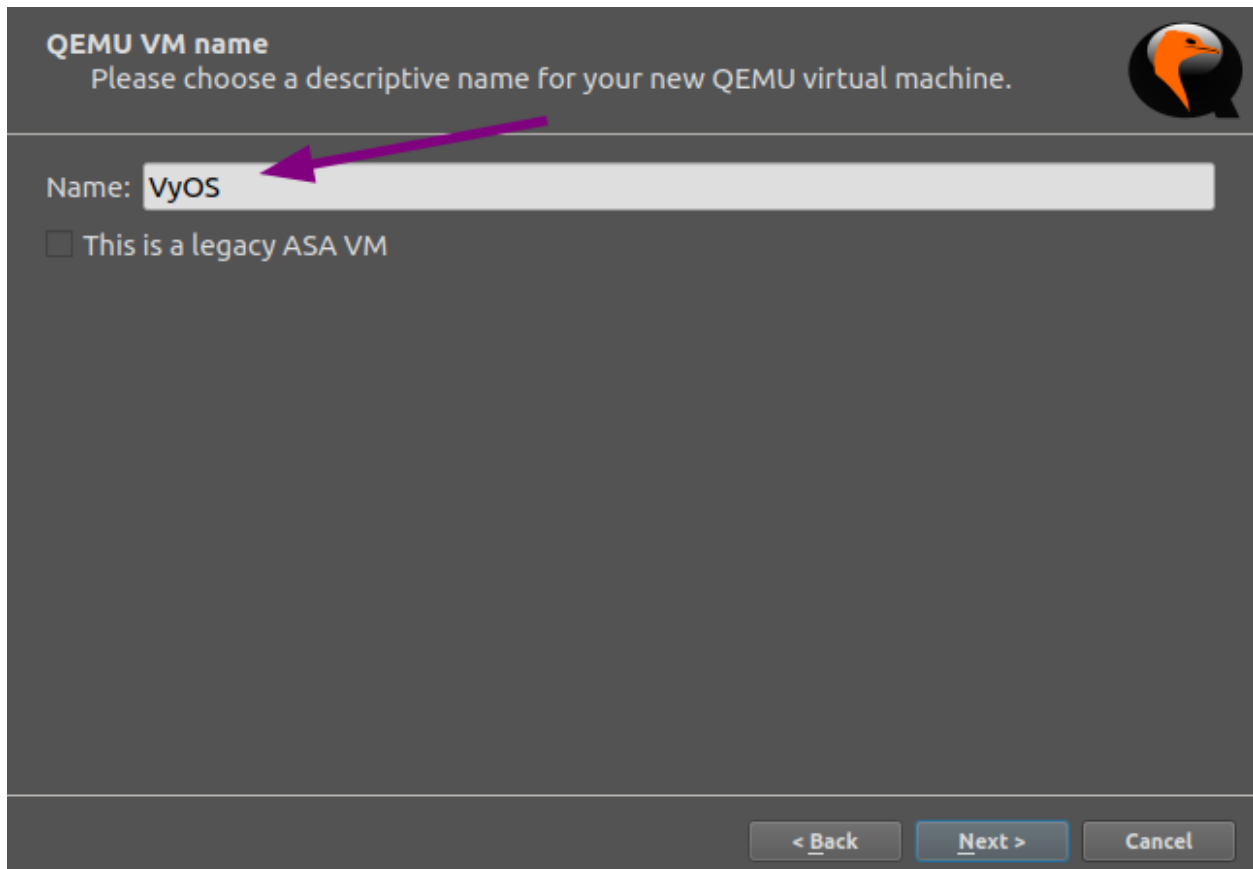

Being again at the **Preferences** window, having **Qemu VMs** selected and having our new VM selected, click the **Edit** button.

In the **General settings** tab of your **QEMU VM template configuration**, do the following:

- Click on the **Browse...** button to choose the **Symbol** you want to have representing your VM.
- In **Category** select in which group you want to find your VM.
- Set the **Boot priority** to **CD/DVD-ROM**.

At the **HDD** tab, change the Disk interface to **sata** to speed up the boot process.

At the **CD/DVD** tab click on **Browse...** and locate the VyOS image you want to install.

**Bemerkung:** You probably will want to accept to copy the .iso file to your default image directory when you are asked.

In the **Network** tab, set **0** as the number of adapters, set the **Name format** to **eth{0}** and the **Type** to **Paravirtualized Network I/O (virtio-net-pci)**.

In the **Advanced** tab, unmark the checkbox **Use as a linked base VM** and click OK, which will save and close the **QEMU VM template configuration** window.

At the general **Preferences** window, click OK to save and close.

## VyOS installation

- Create a new project.
- Drag the newly created VyOS VM into it.
- Start the VM.
- Open a console. The console should show the system booting. It will ask for the login credentials, you are at the VyOS live system.
- *Install VyOS* as normal (that is, using the `install image` command).
- After a successful installation, shutdown the VM with the `poweroff` command.
- **Delete the VM** from the GNS3 project.

The *VyOS-hda.qcow2* file now contains a working VyOS image and can be used as a template. But it still needs some fixes before we can deploy VyOS in our labs.

## VyOS VM configuration

To turn the template into a working VyOS machine, further steps are necessary as outlined below:

**General settings** tab: Set the boot priority to **HDD**

The screenshot shows the 'QEMU VM template configuration' window for a VyOS template. The 'General settings' tab is active. The 'Boot priority' dropdown menu is set to 'HDD', with a red arrow pointing to it. Other configuration options include: Template name (VyOS), Default name format ({name}-{0}), Symbol (./symbols/classic/router.svg), Category (Routers), RAM (512 MB), vCPUs (1), Qemu binary (/usr/bin/qemu-system-x86\_64 (v2.11.1)), On close (Power off the VM), and Console type (telnet). The 'Auto start console' checkbox is unchecked. The window has 'Cancel' and 'OK' buttons at the bottom right.

**CD/DVD** tab: Unmount the installation image file by clearing the **Image** entry field.

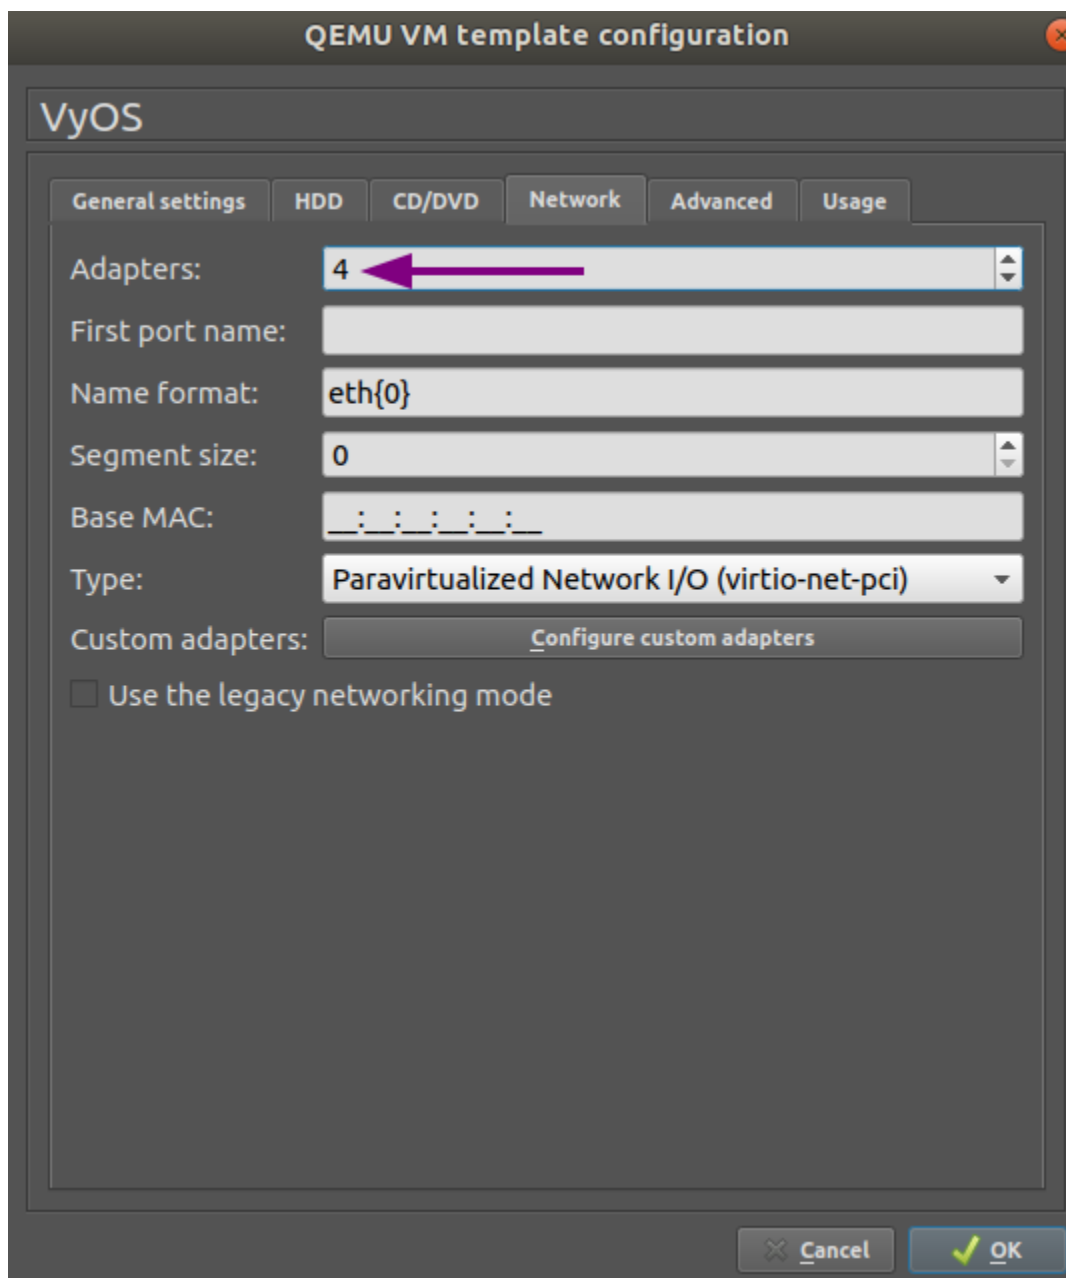

Set the number of required network adapters, for example **4**.

**Advanced** settings tab: Mark the checkbox **Use as a linked base VM** and click OK to save the changes.

The VyOS VM is now ready to be deployed.

## 4.2.5 EVE-NG

### References

<https://www.eve-ng.net/>

## 4.2.6 Running in Docker Container

Docker is an open-source project for deploying applications as standardized units called containers. Deploying VyOS in a container provides a simple and lightweight mechanism for both testing and packet routing for container workloads.

### IPv6 Support for docker

VyOS requires an IPv6-enabled docker network. Currently linux distributions do not enable docker IPv6 support by default. You can enable IPv6 support in two ways.

#### Method 1: Create a docker network with IPv6 support

Here is an example using the macvlan driver.

```
docker network create --ipv6 -d macvlan -o parent=eth0 --subnet 2001:db8::/64 --subnet-  
↪192.0.2.0/24 mynet
```

#### Method 2: Add IPv6 support to the docker daemon

Edit `/etc/docker/daemon.json` to set the `ipv6` key to `true` and to specify the `fixed-cidr-v6` to your desired IPv6 subnet.

```
{  
  "ipv6": true,  
  "fixed-cidr-v6": "2001:db8::/64"  
}
```

Reload the docker configuration.

```
$ sudo systemctl reload docker
```

### Deploy container from ISO

Download the ISO on which you want to base the container. In this example, the name of the ISO is `vyos-1.4-rolling-202308240020-amd64.iso`. If you created a custom IPv6-enabled network, the `docker run` command below will require that this network be included as the `--net` parameter to `docker run`.

```
$ mkdir vyos && cd vyos  
$ curl -o vyos-1.4-rolling-202308240020-amd64.iso https://github.com/vyos/vyos-rolling-  
↪nightly-builds/releases/download/1.4-rolling-202308240020/vyos-1.4-rolling-  
↪202308240020-amd64.iso  
$ mkdir rootfs
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
$ sudo mount -o loop vyos-1.4-rolling-202308240020-amd64.iso rootfs
$ sudo apt-get install -y squashfs-tools
$ mkdir unsquashfs
$ sudo unsquashfs -f -d unsquashfs/ rootfs/live/filesystem.squashfs
$ sudo tar -C unsquashfs -c . | docker import - vyos:1.4-rolling-202111281249
$ sudo umount rootfs
$ cd ..
$ sudo rm -rf vyos
$ docker run -d --rm --name vyos --privileged -v /lib/modules:/lib/modules \
> vyos:1.4-rolling-202111281249 /sbin/init
$ docker exec -ti vyos su - vyos
```

You can execute `docker stop vyos` when you are finished with the container.

## 4.3 Running VyOS in Cloud Environments

### 4.3.1 Amazon AWS

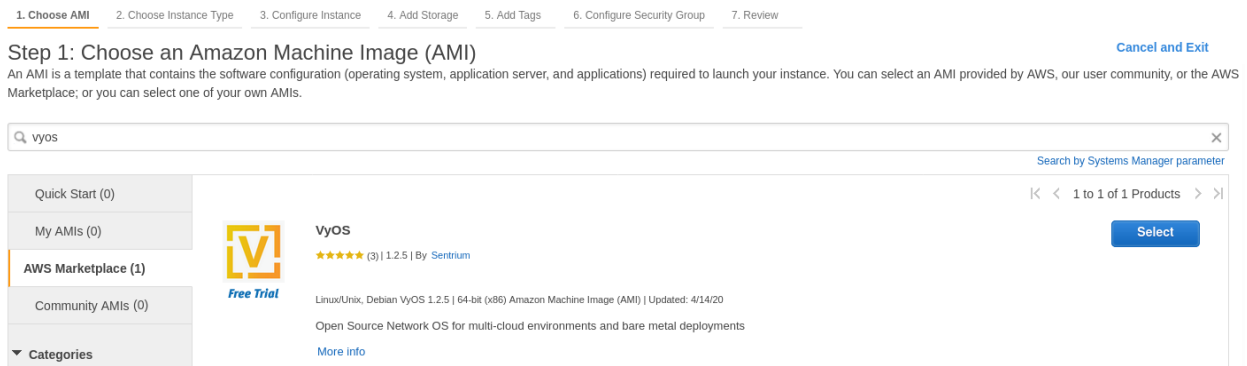

#### Deploy VM

Deploy VyOS on Amazon AWS (Amazon Web Services)

1. Click to Instances and Launch Instance

2. On the marketplace search „VyOS“

### 3. Choose the instance type. Minimum recommendation start from m3.medium

1. Choose AMI	2. Choose Instance Type	3. Configure Instance	4. Add Storage	5. Add Tags	6. Configure Security Group	7. Review
Step 2: Choose an Instance Type						
<input type="checkbox"/>	General purpose	m3.2xlarge	8	30	2 x 80 (SSD)	Yes
<input type="checkbox"/>	General purpose	m3.large	2	7.5	1 x 32 (SSD)	-
<input checked="" type="checkbox"/>	General purpose	m3.medium	1	3.75	1 x 4 (SSD)	-
<input type="checkbox"/>	General purpose	m3.xlarge	4	15	2 x 40 (SSD)	Yes

### 4. Configure instance for your requirements. Select number of instances / network / subnet

1. Choose AMI	2. Choose Instance Type	3. Configure Instance	4. Add Storage	5. Add Tags	6. Configure Security Group	7. Review				
Step 3: Configure Instance Details										
Configure the instance to suit your requirements. You can launch multiple instances from the same AMI, request Spot instances to take advantage of the lower pricing, assign an access management role to the instance, and more.										
Number of instances	1	Launch into Auto Scaling Group								
Purchasing option	<input type="checkbox"/> Request Spot instances									
Network	vpc (default)	Create new VPC								
Subnet	No preference (default subnet in any Availability Zone)	Create new subnet								
Auto-assign Public IP	Use subnet setting (Enable)									
Placement group	<input type="checkbox"/> Add instance to placement group									
Capacity Reservation	Open	Create new Capacity Reservation								
IAM role	None	Create new IAM role								
Shutdown behavior	Stop									
Stop - Hibernate behavior	<input type="checkbox"/> Enable hibernation as an additional stop behavior									
Enable termination protection	<input type="checkbox"/> Protect against accidental termination									
Monitoring	<input type="checkbox"/> Enable CloudWatch detailed monitoring									
<div> Cancel Previous Review and Launch Next: Add Storage </div>										

- Additional storage. You can remove additional storage /dev/sdb. First root device will be /dev/xvda. You can skip this step.
- Configure Security Group. It's recommended that you configure ssh access only from certain address sources. Or permit any (by default).
- Select SSH key pair and click Launch Instances
- Find out your public IP address.
- Connect to the instance by SSH key.

```
ssh -i ~/.ssh/amazon.pem vyos@203.0.113.3
vyos@ip-192-0-2-10:~$
```

1. Choose AMI 2. Choose Instance Type 3. Configure Instance 4. Add Storage 5. Add Tags 6. Configure Security Group 7. Review

#### Step 4: Add Storage

Your instance will be launched with the following storage device settings. You can attach additional EBS volumes and instance store volumes to your instance, or edit the settings of the root volume. You can also attach additional EBS volumes after launching an instance, but not instance store volumes. [Learn more](#) about storage options in Amazon EC2.

Volume Type ⓘ	Device ⓘ	Snapshot ⓘ	Size (GiB) ⓘ	Volume Type ⓘ	IOPS ⓘ	Throughput (MB/s) ⓘ	Delete on Termination ⓘ	Encryption ⓘ
Root	/dev/xvda	snap-0cddde1302124a73fc	4	General Purpose SSD (gp2) ▼	100 / 3000	N/A	<input checked="" type="checkbox"/>	Not Encrypte ▼
Instance Store 0 ▼	/dev/sdb ▼	N/A	4	SSD	N/A	N/A	N/A	Not Encrypted ✕

Add New Volume

Free tier eligible customers can get up to 30 GB of EBS General Purpose (SSD) or Magnetic storage. [Learn more](#) about free usage tier eligibility and usage restrictions.

Cancel Previous **Review and Launch** Next: Add Tags

1. Choose AMI 2. Choose Instance Type 3. Configure Instance 4. Add Storage 5. Add Tags 6. Configure Security Group 7. Review

#### Step 6: Configure Security Group

A security group is a set of firewall rules that control the traffic for your instance. On this page, you can add rules to allow specific traffic to reach your instance. For example, if you want to set up a web server and allow Internet traffic to reach your instance, add rules that allow unrestricted access to the HTTP and HTTPS ports. You can create a new security group or select from an existing one below. [Learn more](#) about Amazon EC2 security groups.

Assign a security group: ☒ Create a new security group

☐ Select an existing security group

Security group name: VyOS-1-2-5-AutogenByAWSMP-

Description: This security group was generated by AWS Marketplace and is based on recomn

Type ⓘ	Protocol ⓘ	Port Range ⓘ	Source ⓘ	Description ⓘ
SSH ▼	TCP	22	Custom ▼ 0.0.0.0/0	e.g. SSH for Admin Desktop ✕

Add Rule

**Warning**  
Rules with source of 0.0.0.0/0 allow all IP addresses to access your instance. We recommend setting security group rules to allow access from known IP addresses only.

Cancel Previous **Review and Launch**

## Select an existing key pair or create a new key pair

A key pair consists of a **public key** that AWS stores, and a **private key file** that you store. Together, they allow you to connect to your instance securely. For Windows AMIs, the private key file is required to obtain the password used to log into your instance. For Linux AMIs, the private key file allows you to securely SSH into your instance.

Note: The selected key pair will be added to the set of keys authorized for this instance. Learn more about [removing existing key pairs from a public AMI](#).

Choose an existing key pair

### Select a key pair

temp

☒ I acknowledge that I have access to the selected private key file (temp.pem), and that without this file, I won't be able to log into my instance.

## Amazon CloudWatch Agent Usage

To use Amazon CloudWatch Agent, configure it within the Amazon SSM Parameter Store. If you don't have a configuration yet, do *CloudWatch SSM Configuration creation*.

1. Create an IAM (Identity and Access Management) role for the EC2 (Elastic Compute Cloud) instance to access CloudWatch service, and name it CloudWatchAgentServerRole. The role should contain two default policies: CloudWatchAgentServerPolicy and AmazonSSMManagedInstanceCore.
2. Attach the created role to your VyOS EC2 instance.
3. Ensure that amazon-cloudwatch-agent package is installed.

```
$ sudo apt list --installed | grep amazon-cloudwatch-agent
```

---

**Bemerkung:** The amazon-cloudwatch-agent package is normally included in VyOS 1.3.3+ and 1.4+

---

3. Retrieve an existing CloudWatch Agent configuration from the SSM (Systems Manager) Parameter Store.

```
$ sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-ctl -a ↵
↵ fetch-config -m ec2 -s -c ssm:<your-configuration-name>
```

This step also enables systemd service and runs it.

---

**Bemerkung:** The VyOS platform-specific scripts feature is under development. Thus, this step should be repeated manually after changing system image (*Update VyOS*)

---

## CloudWatch SSM Configuration creation

Creating the Amazon Cloudwatch Agent Configuration in Amazon SSM Parameter Store.

1. Create an IAM role for your EC2 instance to access the CloudWatch service. Name it CloudWatchAgentAdminRole. The role should contain at two default policies: CloudWatchAgentAdminPolicy and AmazonSSMManagedInstanceCore.

---

**Bemerkung:** CloudWatchAgentServerRole is too permissive and should be used for single configuration creation and deployment. That's why after completion of step #3 highly recommended to replace instance CloudWatchAgentAdminRole role with CloudWatchAgentServerRole.

---

2. Run Cloudwatch configuration wizard.

```
$ sudo /opt/aws/amazon-cloudwatch-agent/bin/amazon-cloudwatch-agent-config- ↵
↵ wizard
```

3. When prompted, answer „yes“ to the question „Do you want to store the config in the SSM parameter store?“.

## Absorbing Routes

If using as a router, you will want your LAN interface to absorb some or all of the traffic from your VNET by using a route table applied to the subnet.

1. Create a route table and browse to **Configuration**
2. Add one or more routes for networks you want to pass through the VyOS VM. Next hop type **Virtual Appliance** with the **Next Hop Address** of the VyOS LAN interface.

---

**Bemerkung:** If you want to create a new default route for VMs on the subnet, use **Address Prefix 0.0.0.0/0** Also note that if you want to use this as a typical edge device, you'll want masquerade NAT for the WAN interface.

---

## Serial Console

Azure has a way to access the serial console of a VM, but this needs to be configured on the VyOS. It's there by default, but keep it in mind if you are replacing config.boot and rebooting: `set system console device ttyS0 speed '9600'`

## References

<https://azure.microsoft.com>

## 4.3.3 Google Cloud Platform

### Deploy VM

To deploy VyOS on GCP (Google Cloud Platform)

1. Generate SSH key pair type **ssh-rsa** from the host that will connect to VyOS.

Example:

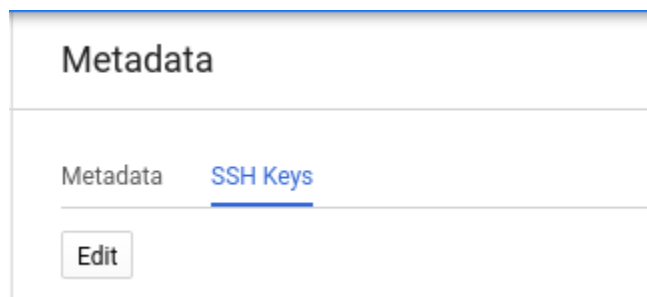

```
ssh-keygen -t rsa -f ~/.ssh/vyos_gcp -C "vyos@mypc"
```

---

**Bemerkung:** In name „vyos@mypc“ The first value must be „vyos“. Because default user is vyos and google api uses this option.

---

2. Open GCP console and navigate to the menu **Metadata**. Choose **SSH Keys** and click edit.

Click **Add item** and paste your public ssh key. Click Save.

vyos

```
ssh-rsa AAAAB3NzaC1yc2EAAAADAQABAAQGDg1UOctMCHb/8AVNndXiFkbuDgKMD00FoY4gS8uLXxOV

## 4.3.4 Oracle

### References

<https://www.oracle.com/cloud/>

## 4.4 Running on Bare Metal

### 4.4.1 Supermicro A2SDi (Atom C3000)

I opted to get one of the new Intel Atom C3000 CPUs to spawn VyOS on it. Running VyOS on an UEFI only device is supported as of VyOS release 1.2.

## Shopping Cart

- 1x Supermicro CSE-505-203B (19" 1U chassis, inkl. 200W PSU)
- 1x Supermicro MCP-260-00085-0B (I/O Shield for A2SDi-2C-HLN4F)
- 1x Supermicro A2SDi-2C-HLN4F (Intel Atom C3338, 2C/2T, 4MB cache, Quad LAN with Intel C3000 SoC 1GbE)
- 1x Crucial CT4G4DFS824A (4GB DDR4 RAM 2400 MT/s, PC4-19200)
- 1x SanDisk Ultra Fit 32GB (USB-A 3.0 SDCZ43-032G-G46 mass storage for OS)
- 1x Supermicro MCP-320-81302-0B (optional FAN tray)

## Optional (10GE)

If you want to get additional ethernet ports or even 10GE connectivity the following optional parts will be required:

- 1x Supermicro RSC-RR1U-E8 (Riser Card)
- 1x Supermicro MCP-120-00063-0N (Riser Card Bracket)

Latest VyOS rolling releases boot without any problem on this board. You also receive a nice IPMI interface realized with an ASPEED AST2400 BMC (no information about [OpenBMC](#) so far on this motherboard).

## Pictures

### 4.4.2 PC Engines APU4

As this platform seems to be quite common in terms of noise, cost, power and performance it makes sense to write a small installation manual.

This guide was developed using an APU4C4 board with the following specs:

- AMD Embedded G series GX-412TC, 1 GHz quad Jaguar core with 64 bit and AES-NI support, 32K data + 32K instruction cache per core, shared 2MB L2 cache.
- 4 GB DDR3-1333 DRAM, with optional ECC support
- About 6 to 10W of 12V DC power depending on CPU load
- 2 miniPCI express (one with SIM socket for 3G modem).
- 4 Gigabit Ethernet channels using Intel i211AT NICs

The board can be powered via 12V from the front or via a 5V onboard connector.

#### Shopping Cart

- 1x apu4c4 = 4 i211AT LAN / AMD GX-412TC CPU / 4 GB DRAM / dual SIM
- 1x Kingston SUV500MS/120G
- 1x VARIA Group Item 326745 19" dual rack for APU4

The 19" enclosure can accommodate up to two APU4 boards - there is a single and dual front cover.

#### Extension Modules

##### WiFi

Refer to [WLAN/WIFI - Wireless LAN](#) for additional information, below listed modules have been tested successfully on this Hardware platform:

- Compex WLE900VX mini-PCIe WiFi module, only supported in mPCIe slot 1.
- Intel Corporation AX200 mini-PCIe WiFi module, only supported in mPCIe slot 1. (see [Intel AX200](#))

##### WWAN

Refer to [WWAN - Wireless Wide-Area-Network](#) for additional information, below listed modules have been tested successfully on this Hardware platform using VyOS 1.3 (equuleus):

- Sierra Wireless AirPrime MC7304 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7430 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7455 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7710 miniPCIe card (LTE)
- Huawei ME909u-521 miniPCIe card (LTE)

## VyOS 1.2 (crux)

Depending on the VyOS versions you intend to install there is a difference in the serial port settings ([T1327](#)).

Create a bootable USB pendrive using e.g. [Rufus](#) on a Windows machine.

Connect serial port to a PC through null modem cable (RXD / TXD crossed over). Set terminal emulator to 115200 8N1.

```
PC Engines apu4
coreboot build 20171130
BIOS version v4.6.4
4080 MB ECC DRAM
SeaBIOS (version rel-1.11.0.1-0-g90da88d)
```

```
Press F10 key now for boot menu:
```

```
Select boot device:
```

- ```
1. ata0-0: KINGSTON SUV500MS120G ATA-11 Hard-Disk (111 GiBytes)
2. USB MSC Drive Generic Flash Disk 8.07
3. Payload [memtest]
4. Payload [setup]
```

Now boot from the USB MSC Drive Generic Flash Disk 8.07 media by pressing 2, the VyOS boot menu will appear, just wait 10 seconds or press **Enter** to continue.

```
lqqk
x                                     VyOS - Boot Menu                                x
tqqqu
x Live (amd64-vyos)  x
x Live (amd64-vyos failsafe)  x
x   x
mqqqqqqPress ENAutomatic boot in 10 seconds...nu entryqqqqqqqqj
```

The image will be loaded and the last lines you will get will be:

```
Loading /live/vmlinuz... ok
Loading /live/initrd.img...
```

The Kernel will now spin up using a different console setting. Set terminal emulator to 9600 8N1 and after a while your console will show:

```

Loading /live/vmlinuz... ok
Loading /live/initrd.img...
Welcome to VyOS - vyos ttyS0

vyos login:

```

You can now proceed with a regular image installation as described in *Installation*.

As the APU board itself still used a serial setting of 115200 8N1 it is strongly recommended that you change the VyOS serial interface settings after your first successful boot.

Use the following command to adjust the *Serial Console* settings:

```
set system console device ttyS0 speed 115200
```

**Bemerkung:** Once you commit the above changes access to the serial interface is lost until you set your terminal emulator to 115200 8N1 again.

```
vyos@vyos# show system console
device ttyS0 {
    speed 115200
}
```

## VyOS 1.2 (rolling)

Installing the rolling release on an APU2 board does not require any change on the serial console from your host side as [T1327](#) was successfully implemented.

Simply proceed with a regular image installation as described in [Installation](#).

## Pictures

**Bemerkung:** Both device types operate without any moving parts and emit zero noise.

## Rack Mount

### VyOS custom print

### Desktop / Bench Top

#### 4.4.3 Qotom Q355G4

The install on this Q355G4 box is pretty much plug and play. The port numbering the OS does might differ from the labels on the outside, but the UEFI firmware has a port blink test built in with MAC addresses so you can very quickly identify which is which. MAC labels are on the inside as well, and this test can be done from VyOS or plain Linux too. Default settings in the UEFI will make it boot, but depending on your installation wishes (i.e. storage type, boot type, console type) you might want to adjust them. This Qotom company seems to be the real OEM/ODM for many other relabelling companies like Protectli.

## Hardware

There are a number of other options, but they all seem to be close to Intel reference designs, with added features like more serial ports, more network interfaces and the likes. Because they don't deviate too much from standard designs all the hardware is well-supported by mainline. It accepts one LPDDR3 SO-DIMM, but chances are that if you need more than that, you'll also want something even beefier than an i5. There are options for antenna holes, and SIM slots, so you could in theory add an LTE/Cell modem (not tested so far).

The chassis is a U-shaped alu extrusion with removable I/O plates and removable bottom plate. Cooling is completely passive with a heatsink on the SoC with internal and external fins, a flat interface surface, thermal pad on top of that, which then directly attaches to the chassis, which has fins as well. It comes with mounting hardware and rubber feet, so you could place it like a desktop model or mount it on a VESA mount, or even wall mount it with the provided mounting plate. The closing plate doubles as internal 2.5" mounting place for an HDD or SSD, and comes supplied with a small SATA cable and SATA power cable.

Power supply is a 12VDC barrel jack, and included switching power supply, which is why SATA power regulation is on-board. Internally it has a NUC-board-style on-board 12V input header as well, the molex locking style.

There are WDT options and auto-boot on power enable, which is great for remote setups. Firmware is reasonably secure (no backdoors found, BootGuard is enabled in enforcement mode, which is good but also means no coreboot option), yet has most options available to configure (so it's not locked out like most firmwares are).

An external RS232 serial port is available, internally a GPIO header as well. It does have Realtek based audio on board for some reason, but you can disable that. Booting works on both USB2 and USB3 ports. Switching between serial BIOS mode and HDMI BIOS mode depends on what is connected at startup; it goes into serial mode if you disconnect HDMI and plug in serial, in all other cases it's HDMI mode.

#### 4.4.4 Partaker i5

I believe this is actually the same hardware as the Protectli. I purchased it in June 2018. It came pre-loaded with pfSense. [Manufacturer product page](#).

#### Installation

- Write VyOS ISO to USB drive of some sort
- Plug in VGA, power, USB keyboard, and USB drive
- Press „SW“ button on the front (this is the power button; I don't know what „SW“ is supposed to mean).
- Begin rapidly pressing delete on the keyboard. The boot prompt is very quick, but with a few tries you should be able to get into the BIOS.
- Chipset > South Bridge > USB Configuration: set XHCI to Disabled and USB 2.0 (EHCI) to Enabled. Without doing this, the USB drive won't boot.
- Boot to the VyOS installer and install as usual.

Warning the interface labels on my device are backwards; the left-most „LAN4“ port is eth0 and the right-most „LAN1“ port is eth3.

#### 4.4.5 Acrosser AND-J190N1

This microbox network appliance was build to create OpenVPN bridges. It can saturate a 100Mbps link. It is a small (serial console only) PC with 6 Gb LAN

You may have to add your own RAM and HDD/SSD. There is no VGA connector. But Acrosser provides a DB25 adapter for the VGA header on the motherboard (not used).

### BIOS Settings:

First thing you want to do is getting a more user friendly console to configure BIOS. Default VT100 brings a lot of issues. Configure VT100+ instead.

For practical issues change speed from 115200 to 9600. 9600 is the default speed at which both linux kernel and VyOS will reconfigure the serial port when loading.

Connect to serial (115200bps). Power on the appliance and press Del in the console when requested to enter BIOS settings.

Advanced > Serial Port Console Redirection > Console Redirection Settings:

- Terminal Type : VT100+
- Bits per second : 9600

Save, reboot and change serial speed to 9600 on your client.

Some options have to be changed for VyOS to boot correctly. With XHCI enabled the installer can't access the USB key. Enable EHCI instead.

Reboot into BIOS, Chipset > South Bridge > USB Configuration:

- Disable XHCI
- Enable USB 2.0 (EHCI) Support

## Install VyOS:

Create a VyOS bootable USB key. I used the 64-bit ISO (VyOS 1.1.7) and [LinuxLive USB Creator](#).

I'm not sure if it helps the process but I changed default option to live-serial (line "default xxxx") on the USB key under `syslinux/syslinux.cfg`.

I connected the key to one black USB port on the back and powered on. The first VyOS screen has some readability issues. Press **Enter** to continue.

Then VyOS should boot and you can perform the `install image`

## 4.5 Update VyOS

New system images can be added using the `add system image` command. The command will extract the chosen image and will prompt you to use the current system configuration and SSH security keys, allowing for the new image to boot using the current configuration.

---

**Bemerkung:** Only LTS releases are PGP-signed.

---

**add system image** <url | path> | [latest] [vrf name] [username user [password pass]]

Use this command to install a new system image. You can reach the image from the web (`http://`, `https://`) or from your local system, e.g. `/tmp/vyos-1.2.3-amd64.iso`.

The `add system image` command also supports installing new versions of VyOS through an optional given VRF. Also if URL in question requires authentication, you can specify an optional username and password via the commandline which will be passed as „Basic-Auth“ to the server.

If there is not enough **free disk space available**, the installation will be canceled. To delete images use the `delete system image` command.

VyOS configuration is associated to each image, and **each image has a unique copy of its configuration**. This is different than a traditional network router where the configuration is shared across all images.

---

**Bemerkung:** If you have any personal files, like some scripts you created, and you don't want them to be lost during the upgrade, make sure those files are stored in `/config` as this directory is always copied to newer installed images.

---

You can access files from a previous installation and copy them to your current image if they were located in the `/config` directory. This can be done using the `copy` command. So, for instance, in order to copy `/config/config.boot` from VyOS 1.2.1 image, you would use the following command:

```
copy file 1.2.1://config/config.boot to /tmp/config.boot.1.2.1
```

### 4.5.1 Example

```
vyos@vyos:~$ add system image https://s3.amazonaws.com/s3-us.vyos.io/rolling/current/
↪vyos-1.4-rolling-202201120317-amd64.iso
Trying to fetch ISO file from https://s3.amazonaws.com/s3-us.vyos.io/rolling/current/
↪vyos-1.4-rolling-202201120317-amd64.iso
  % Total      % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left   Speed
100 338M 100 338M    0     0 3837k      0  0:01:30  0:01:30 --:--:-- 3929k
ISO download succeeded.
Checking for digital signature file...
  % Total      % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left   Speed
  0     0    0     0    0     0      0      0  --:--:--  --:--:--  --:--:--    0
curl: (22) The requested URL returned error: 404 Not Found

Unable to fetch digital signature file.
Do you want to continue without signature check? (yes/no) [yes]
Checking MD5 checksums of files on the ISO image...OK.
Done!

What would you like to name this image? [vyos-1.3-rolling-201912201452]:

OK. This image will be named: vyos-1.3-rolling-201912201452
```

You can use `latest` option. It loads the latest available Rolling release.

```
vyos@vyos:~$ add system image latest
```

---

**Bemerkung:** To use the *latest* option the „system update-check url“ must be configured.

---

---

**Hinweis:** The most up-to-date Rolling Release for AMD64 can be accessed using the following URL:

<https://vyos.net/get/nightly-builds/>

---

After reboot you might want to verify the version you are running with the `show version` command.

## 4.6 Image Management

The VyOS image-based installation is implemented by creating a directory for each image on the storage device selected during the install process.

The directory structure of the boot device:

```
/
/boot
/boot/grub
/boot/1.2.0-rolling+201810021347
```

The image directory contains the system kernel, a compressed image of the root filesystem for the OS, and a directory for persistent storage, such as configuration. On boot, the system will extract the OS image into memory and mount the appropriate live-rw sub-directories to provide persistent storage system configuration.

This process allows for a system to always boot to a known working state, as the OS image is fixed and non-persistent. It also allows for multiple releases of VyOS to be installed on the same storage device. The image can be selected manually at boot if needed, but the system will otherwise boot the image configured to be the default.

### show system image

List all available system images which can be booted on the current system.

```
vyos@vyos:~$ show system image
The system currently has the following image(s) installed:

1: 1.2.0-rolling+201810021347 (default boot)
2: 1.2.0-rolling+201810021217
3: 1.2.0-rolling+201809252218
```

### delete system image [image-name]

Delete no longer needed images from the system. You can specify an optional image name to delete, the image name can be retrieved via a list of available images can be shown using the `show system image`.

```
vyos@vyos:~$ delete system image
The following image(s) can be deleted:

1: 1.3-rolling-201912181733 (default boot) (running image)
2: 1.3-rolling-201912180242
3: 1.2.2
4: 1.2.1

Select the image to delete: 2

Are you sure you want to delete the
"1.3-rolling-201912180242" image? (Yes/No) [No]: y
Deleting the "1.3-rolling-201912180242" image...
Done
```

### show version

Show current system image version.

```
vyos@vyos:~$ show version
Version:          VyOS 1.3-rolling-201912181733
Built by:         autobuild@vyos.net
Built on:         Wed 18 Dec 2019 17:33 UTC

### 4.6.1 System rollback

If you need to rollback to a previous image, you can easily do so. First check the available images through the `show system image` command and then select your image with the following command:

```
set system image default-boot [image-name]
```

Select the default boot image which will be started on the next boot of the system.

Then reboot the system.

---

**Bemerkung:** VyOS automatically associates the configuration to the image, so you don't need to worry about that. Each image has a unique copy of its configuration.

---

If you have access to the console, there is another way to select your booting image: reboot and use the GRUB menu at startup.

## 4.7 Migrate from Vyatta Core

VyOS 1.x line aims to preserve backward compatibility and provide a safe upgrade path for existing Vyatta Core users. You may think of VyOS 1.0.0 as VC7.0.

### 4.7.1 Vyatta release compatibility

Vyatta Core releases from 6.5 to 6.6 should be 100% compatible.

Vyatta Core 6.4 and earlier may have incompatibilities. In Vyatta 6.5 the „modify“ firewall was removed and replaced with the `set policy route` command family, old configs can not be automatically converted. You will have to adapt it to post-6.5 Vyatta syntax manually.

---

**Bemerkung:** Also, in Vyatta Core 6.5 remote access VPN interfaces have been renamed from `pppX` to `l2tpX` and `pptpX`. If you are using zone based firewalling in Vyatta Core pre-6.5 versions, make sure to change interface names in rules for remote access VPN.

---

### 4.7.2 Upgrade procedure

You just use `add system image`, as if it was a new VC release (see [Update VyOS](#) for additional information). The only thing you want to do is to verify the new images digital signature. You will have to add the public key manually once as it is not shipped the first time.

```
vyatta@vyatta:~$ wget http://wiki.vyos.net/so3group_maintainers.key
Connecting to vyos.net (x.x.x.x:80)
so3group_maintainers 100% |*****| 3125 --:--:-- ETA
vyatta@vyatta:~$ sudo apt-key add so3group_maintainers.key
OK
vyatta@vyatta:~$
```

For completion the key below corresponds to the key listed in the URL above.

```

vyatta@vyatta:~$ show system image
The system currently has the following image(s) installed:

  1: 1.0.0 (default boot)
  2: VC6.6R1 (running image)
```

Upon reboot, you should have a working installation of VyOS.

You can go back to your Vyatta install using the `set system image default-boot` command and selecting the your previous Vyatta Core image.

---

**Bemerkung:** Future releases of VyOS will break the direct upgrade path from Vyatta core. Please upgrade through an intermediate VyOS version e.g. VyOS 1.2. After this you can continue upgrading to newer releases once you bootet into VyOS 1.2 once.

---

This chapter will guide you on how to get up to speed quickly using your new VyOS system. It will show you a very basic configuration example that will provide a *NAT* gateway for a device with two network interfaces (`eth0` and `eth1`).

## 5.1 Configuration Mode

By default, VyOS is in operational mode, and the command prompt displays a `$`. To configure VyOS, you will need to enter configuration mode, resulting in the command prompt displaying a `#`, as demonstrated below:

```
vyos@vyos$ configure
vyos@vyos#
```

## 5.2 Commit and Save

After every configuration change, you need to apply the changes by using the following command:

```
commit
```

Once your configuration works as expected, you can save it permanently by using the following command:

```
save
```

## 5.3 Interface Configuration

- Your outside/WAN interface will be `eth0`. It will receive its interface address via DHCP.
- Your internal/LAN interface will be `eth1`. It will use a static IP address of `192.168.0.1/24`.

After switching to *Configuration Mode* issue the following commands:

```
set interfaces ethernet eth0 address dhcp
set interfaces ethernet eth0 description 'OUTSIDE'
set interfaces ethernet eth1 address '192.168.0.1/24'
set interfaces ethernet eth1 description 'LAN'
```

## 5.4 SSH Management

After switching to *Configuration Mode* issue the following commands, and your system will listen on every interface for incoming SSH connections. You might want to check the *SSH* chapter on how to listen on specific addresses only.

```
set service ssh port '22'
```

## 5.5 DHCP/DNS quick-start

The following settings will configure DHCP and DNS services on your internal/LAN network, where VyOS will act as the default gateway and DNS server.

- The default gateway and DNS recursor address will be `192.168.0.1/24`
- The address range `192.168.0.2/24` - `192.168.0.8/24` will be reserved for static assignments
- DHCP clients will be assigned IP addresses within the range of `192.168.0.9` - `192.168.0.254` and have a domain name of `internal-network`
- DHCP leases will hold for one day (86400 seconds)
- VyOS will serve as a full DNS recursor, replacing the need to utilize Google, Cloudflare, or other public DNS servers (which is good for privacy)
- Only hosts from your internal/LAN network can use the DNS recursor

```
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 option default-
↪router '192.168.0.1'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 option name-server
↪'192.168.0.1'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 option domain-name
↪'vyos.net'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 lease '86400'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 range 0 start '192.
↪168.0.9'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 range 0 stop '192.
↪168.0.254'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 subnet-id '1'

set service dns forwarding cache-size '0'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set service dns forwarding listen-address '192.168.0.1'
set service dns forwarding allow-from '192.168.0.0/24'
```

## 5.6 NAT

The following settings will configure [SNAT](#) rules for our internal/LAN network, allowing hosts to communicate through the outside/WAN network via IP masquerade.

```
set nat source rule 100 outbound-interface name 'eth0'
set nat source rule 100 source address '192.168.0.0/24'
set nat source rule 100 translation address masquerade
```

## 5.7 Firewall

A new firewall structure—which uses the `nftables` backend, rather than `iptables`—is available on all installations starting from VyOS 1.4-rolling-202308040557. The firewall supports creation of distinct, interlinked chains for each [Netfilter hook](#) and allows for more granular control over the packet filtering process.

The firewall begins with the base `filter` tables you define for each of the `forward`, `input`, and `output` Netfilter hooks. Each of these tables is populated with rules that are processed in order and can jump to other chains for more granular filtering.

### 5.7.1 Configure Firewall Groups

To make firewall configuration easier, we can create groups of interfaces, networks, addresses, ports, and domains that describe different parts of our network. We can then use them for filtering within our firewall rulesets, allowing for more concise and readable configuration.

In this case, we will create two interface groups — a WAN group for our interfaces connected to the public internet and a LAN group for the interfaces connected to our internal network. Additionally, we will create a network group, `NET-INSIDE-v4`, that contains our internal subnet.

```
set firewall group interface-group WAN interface eth0
set firewall group interface-group LAN interface eth1
set firewall group network-group NET-INSIDE-v4 network '192.168.0.0/24'
```

### 5.7.2 Configure Stateful Packet Filtering

With the new firewall structure, we have a lot of flexibility in how we group and order our rules, as shown by the three alternative approaches below.

### Option 1: Global State Policies

Using options defined in `set firewall global-options state-policy`, state policy rules that applies for both IPv4 and IPv6 are created. These global state policies also applies for all traffic that passes through the router (transit) and for traffic originated/destinated to/from the router itself, and will be evaluated before any other rule defined in the firewall.

Most installations would choose this option, and will contain:

```
set firewall global-options state-policy established action accept
set firewall global-options state-policy related action accept
set firewall global-options state-policy invalid action drop
```

### Option 2: Common/Custom Chain

We can create a common chain for stateful connection filtering of multiple interfaces (or multiple netfilter hooks on one interface). Those individual chains can then jump to the common chain for stateful connection filtering, returning to the original chain for further rule processing if no action is taken on the packet.

The chain we will create is called `CONN_FILTER` and has three rules:

- A default action of `return`, which returns the packet back to the original chain if no action is taken.
- A rule to `accept` packets from established and related connections.
- A rule to `drop` packets from invalid connections.

```
set firewall ipv4 name CONN_FILTER default-action 'return'

set firewall ipv4 name CONN_FILTER rule 10 action 'accept'
set firewall ipv4 name CONN_FILTER rule 10 state established
set firewall ipv4 name CONN_FILTER rule 10 state related

set firewall ipv4 name CONN_FILTER rule 20 action 'drop'
set firewall ipv4 name CONN_FILTER rule 20 state invalid
```

Then, we can jump to the common chain from both the forward and input hooks as the first filtering rule in the respective chains:

```
set firewall ipv4 forward filter rule 10 action 'jump'
set firewall ipv4 forward filter rule 10 jump-target CONN_FILTER

set firewall ipv4 input filter rule 10 action 'jump'
set firewall ipv4 input filter rule 10 jump-target CONN_FILTER
```

### Option 3: Per-Hook Chain

Alternatively, you can take the more traditional stateful connection filtering approach by creating rules on each base hook's chain:

```
set firewall ipv4 forward filter rule 5 action 'accept'
set firewall ipv4 forward filter rule 5 state established
set firewall ipv4 forward filter rule 5 state related
set firewall ipv4 forward filter rule 10 action 'drop'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set firewall ipv4 forward filter rule 10 state invalid

set firewall ipv4 input filter rule 5 action 'accept'
set firewall ipv4 input filter rule 5 state established
set firewall ipv4 input filter rule 5 state related
set firewall ipv4 input filter rule 10 action 'drop'
set firewall ipv4 input filter rule 10 state invalid
```

### 5.7.3 Block Incoming Traffic

Now that we have configured stateful connection filtering to allow traffic from established and related connections, we can block all other incoming traffic addressed to our local network.

Create a new chain (OUTSIDE-IN) which will drop all traffic that is not explicitly allowed at some point in the chain. Then, we can jump to that chain from the `forward` hook when traffic is coming from the WAN interface group and is addressed to our local network.

```
set firewall ipv4 name OUTSIDE-IN default-action 'drop'

set firewall ipv4 forward filter rule 100 action jump
set firewall ipv4 forward filter rule 100 jump-target OUTSIDE-IN
set firewall ipv4 forward filter rule 100 inbound-interface group WAN
set firewall ipv4 forward filter rule 100 destination group network-group NET-INSIDE-v4
```

We should also block all traffic destined to the router itself that isn't explicitly allowed at some point in the chain for the `input` hook. As we've already configured stateful packet filtering above, we only need to set the default action to `drop`:

```
set firewall ipv4 input filter default-action 'drop'
```

### 5.7.4 Allow Management Access

We can now configure access to the router itself, allowing SSH access from the inside/LAN network and rate limiting SSH access from the outside/WAN network.

First, create a new dedicated chain (VyOS\_MANAGEMENT) for management access, which returns to the parent chain if no action is taken. Add a rule to accept traffic from the LAN interface group:

```
set firewall ipv4 name VyOS_MANAGEMENT default-action 'return'
```

Configure a rule on the `input` hook filter to jump to the VyOS\_MANAGEMENT chain when new connections are addressed to port 22 (SSH) on the router itself:

```
set firewall ipv4 input filter rule 20 action jump
set firewall ipv4 input filter rule 20 jump-target VyOS_MANAGEMENT
set firewall ipv4 input filter rule 20 destination port 22
set firewall ipv4 input filter rule 20 protocol tcp
```

Finally, configure the VyOS\_MANAGEMENT chain to accept connection from the LAN interface group while limiting requests coming from the WAN interface group to 4 per minute:

```

set firewall ipv4 name VyOS_MANAGEMENT rule 15 action 'accept'
set firewall ipv4 name VyOS_MANAGEMENT rule 15 inbound-interface group 'LAN'

set firewall ipv4 name VyOS_MANAGEMENT rule 20 action 'drop'
set firewall ipv4 name VyOS_MANAGEMENT rule 20 recent count 4
set firewall ipv4 name VyOS_MANAGEMENT rule 20 recent time minute
set firewall ipv4 name VyOS_MANAGEMENT rule 20 state new
set firewall ipv4 name VyOS_MANAGEMENT rule 20 inbound-interface group 'WAN'

set firewall ipv4 name VyOS_MANAGEMENT rule 21 action 'accept'
set firewall ipv4 name VyOS_MANAGEMENT rule 21 state new
set firewall ipv4 name VyOS_MANAGEMENT rule 21 inbound-interface group 'WAN'

```

### 5.7.5 Allow Access to Services

Here we're allowing the router to respond to pings. Then, we can allow access to the DNS recursor we configured earlier, accepting traffic bound for port 53 from all hosts on the NET-INSIDE-v4 network:

```

set firewall ipv4 input filter rule 30 action 'accept'
set firewall ipv4 input filter rule 30 icmp type-name 'echo-request'
set firewall ipv4 input filter rule 30 protocol 'icmp'
set firewall ipv4 input filter rule 30 state new

set firewall ipv4 input filter rule 40 action 'accept'
set firewall ipv4 input filter rule 40 destination port '53'
set firewall ipv4 input filter rule 40 protocol 'tcp_udp'
set firewall ipv4 input filter rule 40 source group network-group NET-INSIDE-v4

```

Finally, we can now configure access to the services running on this router, allowing all connections coming from localhost:

```

set firewall ipv4 input filter rule 50 action 'accept'
set firewall ipv4 input filter rule 50 source address 127.0.0.0/8

```

Commit changes, save the configuration, and exit configuration mode:

```

vyos@vyos# commit
vyos@vyos# save
Saving configuration to '/config/config.boot'...
Done
vyos@vyos# exit
vyos@vyos$

```

## 5.8 Hardening

Especially if you are allowing SSH remote access from the outside/WAN interface, there are a few additional configuration steps that should be taken.

Replace the default vyos system user:

```
set system login user myvyosuser authentication plaintext-password mysecurepassword
```

Set up *Key Based Authentication*:

```
set system login user myvyosuser authentication public-keys myusername@mydesktop type_
↪ssh-rsa
set system login user myvyosuser authentication public-keys myusername@mydesktop key_
↪contents_of_id_rsa.pub
```

Finally, try and SSH into the VyOS install as your new user. Once you have confirmed that your new user can access your router without a password, delete the original vyos user and completely disable password authentication for *SSH*:

```
delete system login user vyos
set service ssh disable-password-authentication
```

As above, commit your changes, save the configuration, and exit configuration mode:

```
vyos@vyos# commit
vyos@vyos# save
Saving configuration to '/config/config.boot'...
Done
vyos@vyos# exit
vyos@vyos$
```

You now should have a simple yet secure and functioning router to experiment with further. Enjoy!

---

## Command Line Interface

---

The VyOS CLI (Command-Line Interface) comprises an operational and a configuration mode.

### 6.1 Operational Mode

Operational mode allows for commands to perform operational system tasks and view system and service status, while configuration mode allows for the modification of system configuration.

The CLI provides a built-in help system. In the CLI the ? key may be used to display available commands. The TAB key can be used to auto-complete commands and will present the help system upon a conflict or unknown value.

For example typing `sh` followed by the TAB key will complete to `show`. Pressing TAB a second time will display the possible sub-commands of the `show` command.

```
vyos@vyos:~$ s[tab]
set  show
```

Example showing possible show commands:

```
vyos@vyos:~$ show [tab]
Possible completions:
  arp          Show Address Resolution Protocol (ARP) information
  bridge       Show bridging information
  cluster      Show clustering information
  configuration Show running configuration
  conntrack    Show conntrack entries in the conntrack table
  conntrack-sync
               Show connection syncing information
  date         Show system date and time
  dhcp         Show Dynamic Host Configuration Protocol (DHCP) information
  dhcpv6       Show status related to DHCPv6
  disk         Show status of disk device
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

dns          Show Domain Name Server (DNS) information
file         Show files for a particular image
firewall     Show firewall information
flow-accounting
             Show flow accounting statistics
hardware     Show system hardware details
history      show command history
host         Show host information
incoming     Show ethernet input-policy information
: q

```

You can scroll up with the keys [Shift]+[PageUp] and scroll down with [Shift]+[PageDown].

When the output of a command results in more lines than can be displayed on the terminal screen the output is paginated as indicated by a : prompt.

**When viewing in page mode the following commands are available:**

- q key can be used to cancel output
- space will scroll down one page
- b will scroll back one page
- return will scroll down one line
- up-arrow and down-arrow will scroll up or down one line at a time respectively
- left-arrow and right-arrow can be used to scroll left or right in the event that the output has lines which exceed the terminal size.

## 6.2 Configuration Mode

To enter configuration mode use the `configure` command:

```

vyos@vyos:~$ configure
[edit]
vyos@vyos:~#

```

---

**Bemerkung:** Prompt changes from \$ to #. To exit configuration mode, type `exit`.

---

```

vyos@vyos:~# exit
exit
vyos@vyos:~$

```

See the configuration section of this document for more information on configuration mode.

---

## Configuration Overview

---

VyOS makes use of a unified configuration file for the entire system's configuration: `/config/config.boot`. This allows easy template creation, backup, and replication of system configuration. A system can thus also be easily cloned by simply copying the required configuration files.

### 7.1 Terminology

A VyOS system has three major types of configurations:

- **Active** or **running configuration** is the system configuration that is loaded and currently active (used by VyOS). Any change in the configuration will have to be committed to belong to the active/running configuration.
- **Working configuration** is the one that is currently being modified in configuration mode. Changes made to the working configuration do not go into effect until the changes are committed with the `commit` command. At which time the working configuration will become the active or running configuration.
- **Saved configuration** is the one saved to a file using the `save` command. It allows you to keep safe a configuration for future uses. There can be multiple configuration files. The default or „boot“ configuration is saved and loaded from the file `/config/config.boot`.

#### 7.1.1 Seeing and navigating the configuration

##### **show configuration**

View the current active configuration, also known as the running configuration, from the operational mode.

```
vyos@vyos:~$ show configuration
interfaces {
    ethernet eth0 {
        address dhcp
        hw-id 00:53:00:00:aa:01
    }
}
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
    loopback lo {
    }
}
service {
    ssh {
        port 22
    }
}
system {
    config-management {
        commit-revisions 20
    }
    console {
        device ttyS0 {
            speed 9600
        }
    }
    login {
        user vyos {
            authentication {
                encrypted-password *****
            }
            level admin
        }
    }
    ntp {
        server 0.pool.ntp.org {
        }
        server 1.pool.ntp.org {
        }
        server 2.pool.ntp.org {
        }
    }
    syslog {
        global {
            facility all {
                level notice
            }
            facility protocols {
                level debug
            }
        }
    }
}
```

By default, the configuration is displayed in a hierarchy like the above example, this is only one of the possible ways to display the configuration. When the configuration is generated and the device is configured, changes are added through a collection of `set` and `delete` commands.

### show configuration commands

Get a collection of all the set commands required which led to the running configuration.

```
vyos@vyos:~$ show configuration commands
set interfaces ethernet eth0 address 'dhcp'
set interfaces ethernet eth0 hw-id '00:53:dd:44:3b:0f'
set interfaces loopback 'lo'
set service ssh port '22'
set system config-management commit-revisions '20'
set system console device ttyS0 speed '9600'
set system login user vyos authentication encrypted-password '$6$Vt68...QzF0'
set system login user vyos level 'admin'
set system ntp server '0.pool.ntp.org'
set system ntp server '1.pool.ntp.org'
set system ntp server '2.pool.ntp.org'
set system syslog global facility all level 'notice'
set system syslog global facility protocols level 'debug'
```

Both these show commands should be executed when in operational mode, they do not work directly in configuration mode. There is a special way on how to [Access opmode from config mode](#).

---

**Hinweis:** Use the `show configuration commands | strip-private` command when you want to hide private data. You may want to do so if you want to share your configuration on the [forum](#).

---

### show configuration json

View the current active configuration in JSON format.

```
{"interfaces": {"ethernet": {"eth0": {"address": ["192.0.2.11/24", "192.0.2.35/24"],
↪ "hw-id": "52:54:00:48:a0:c6"}, "eth1": {"address": ["203.0.113.1/24"], "hw-id":

        },
        "protocols": {
          "level": "debug"
        }
      }
    }
  },
  "time-zone": "America/New_York"
}

```

## The config mode

When entering the configuration mode you are navigating inside a tree structure, to enter configuration mode enter the command `configure` when in operational mode.

```

vyos@vyos$ configure
[edit]
vyos@vyos#

```

---

**Bemerkung:** When going into configuration mode, prompt changes from \$ to #.

---

All commands executed here are relative to the configuration level you have entered. You can do everything from the top level, but commands will be quite lengthy when manually typing them.

The current hierarchy level can be changed by the `edit` command.

```

[edit]
vyos@vyos# edit interfaces ethernet eth0

[edit interfaces ethernet eth0]
vyos@vyos#

```

You are now in a sublevel relative to `interfaces ethernet eth0`, all commands executed from this point on are

relative to this sublevel. Use either the `top` or `exit` command to go back to the top of the hierarchy. You can also use the `up` command to move only one level up at a time.

### show

The `show` command within configuration mode will show the working configuration indicating line changes with `+` for additions, `>` for replacements and `-` for deletions.

### Example:

```
vyos@vyos:~$ configure
[edit]
vyos@vyos# show interfaces
  ethernet eth0 {
    description MY_OLD_DESCRIPTION
    disable
    hw-id 00:53:dd:44:3b:03
  }
  loopback lo {
  }
[edit]
vyos@vyos# set interfaces ethernet eth0 address dhcp
[edit]
vyos@vyos# set interfaces ethernet eth0 description MY_NEW_DESCRIPTION
[edit]
vyos@vyos# delete interfaces ethernet eth0 disable
[edit]
vyos@vyos# show interfaces
  ethernet eth0 {
+   address dhcp
>   description MY_NEW_DESCRIPTION
-   disable
    hw-id 00:53:dd:44:3b:03
  }
  loopback lo {
  }
```

It is also possible to display all set commands within configuration mode using `show | commands`

```
vyos@vyos# show interfaces ethernet eth0 | commands
set address dhcp
set hw-id 00:53:ad:44:3b:03
```

These commands are also relative to the level you are inside and only relevant configuration blocks will be displayed when entering a sub-level.

```
[edit interfaces ethernet eth0]
vyos@vyos# show
  address dhcp
  hw-id 00:53:ad:44:3b:03
```

Exiting from the configuration mode is done via the `exit` command from the top level, executing `exit` from within a sub-level takes you back to the top level.

```
[edit interfaces ethernet eth0]
vyos@vyos# exit
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
[edit]
vyos@vyos# exit
Warning: configuration changes have not been saved.
```

## 7.1.2 Editing the configuration

The configuration can be edited by the use of `set` and `delete` commands from within configuration mode.

### set

Use this command to set the value of a parameter or to create a new element.

Configuration commands are flattened from the tree into 'one-liner' commands shown in `show configuration` commands from operation mode. Commands are relative to the level where they are executed and all redundant information from the current level is removed from the command entered.

```
[edit]
vyos@vyos# set interface ethernet eth0 address 192.0.2.100/24
```

```
[edit interfaces ethernet eth0]
vyos@vyos# set address 203.0.113.6/24
```

These two commands above are essentially the same, just executed from different levels in the hierarchy.

### delete

To delete a configuration entry use the `delete` command, this also deletes all sub-levels under the current level you've specified in the `delete` command. Deleting an entry will also result in the element reverting back to its default value if one exists.

```
[edit interfaces ethernet eth0]
vyos@vyos# delete address 192.0.2.100/24
```

### commit

Any change you do on the configuration, will not take effect until committed using the `commit` command in configuration mode.

```
vyos@vyos# commit
[edit]
vyos@vyos# exit
Warning: configuration changes have not been saved.
vyos@vyos:~$
```

---

**Hinweis:** You can specify a commit message with `commit comment <message>`.

---

### save

Use this command to preserve configuration changes upon reboot. By default it is stored at `/config/config.boot`. In the case you want to store the configuration file somewhere else, you can add a local path, a SCP address, a FTP address or a TFTP address.

```
vyos@vyos# save
Saving configuration to '/config/config.boot'...
Done
```

```
vyos@vyos# save [tab]
Possible completions:
  <Enter>      Save to system config file
  <file>       Save to file on local machine
  scp://<user>:<passwd>@<host>:<file> Save to file on remote machine
  ftp://<user>:<passwd>@<host>:<file> Save to file on remote machine
  tftp://<host>:<file>      Save to file on remote machine
vyos@vyos# save tftp://192.168.0.100/vyos-test.config.boot
Saving configuration to 'tftp://192.168.0.100/vyos-test.config.boot'...
##### 100.0%
Done
```

### exit [discard]

Configuration mode can not be exited while uncommitted changes exist. To exit configuration mode without applying changes, the `exit discard` command must be used.

All changes in the working config will thus be lost.

```
vyos@vyos# exit
Cannot exit: configuration modified.
Use 'exit discard' to discard the changes and exit.
[edit]
vyos@vyos# exit discard
```

### commit-confirm <minutes>

Use this command to temporarily commit your changes and set the number of minutes available for validation. `confirm` must be entered within those minutes, otherwise the system will reboot into the previous configuration. The default value is 10 minutes.

What if you are doing something dangerous? Suppose you want to setup a firewall, and you are not sure there are no mistakes that will lock you out of your system. You can use confirmed commit. If you issue the `commit-confirm` command, your changes will be committed, and if you don't issue the `confirm` command in 10 minutes, your system will reboot into previous config revision.

```
vyos@router# set firewall interface eth0 local name FromWorld
vyos@router# commit-confirm
commit confirm will be automatically reboot in 10 minutes unless confirmed
Proceed? [confirm]y
[edit]
vyos@router# confirm
[edit]
```

---

**Bemerkung:** A reboot because you did not enter `confirm` will not take you necessarily to the *saved configuration*, but to the point before the unfortunate commit.

---

### copy

Copy a configuration element.

You can copy and remove configuration subtrees. Suppose you set up a firewall ruleset `FromWorld` with one rule that allows traffic from specific subnet. Now you want to setup a similar rule, but for different subnet. Change your edit level to `firewall name FromWorld` and use `copy rule 10 to rule 20`, then modify rule 20.

```
vyos@router# show firewall name FromWorld
default-action drop
rule 10 {
    action accept
    source {
        address 203.0.113.0/24
    }
}
[edit]
vyos@router# edit firewall name FromWorld
[edit firewall name FromWorld]
vyos@router# copy rule 10 to rule 20
[edit firewall name FromWorld]
vyos@router# set rule 20 source address 198.51.100.0/24
[edit firewall name FromWorld]
vyos@router# commit
[edit firewall name FromWorld]
```

## rename

Rename a configuration element.

You can also rename config subtrees:

```
vyos@router# rename rule 10 to rule 5
[edit firewall name FromWorld]
vyos@router# commit
[edit firewall name FromWorld]
```

Note that `show` command respects your edit level and from this level you can view the modified firewall ruleset with just `show` with no parameters.

```
vyos@router# show
default-action drop
rule 5 {
    action accept
    source {
        address 203.0.113.0/24
    }
}
rule 20 {
    action accept
    source {
        address 198.51.100.0/24
    }
}
```

## comment <config node> „comment text“

Add comment as an annotation to a configuration node.

The `comment` command allows you to insert a comment above the `<config node>` configuration section. When shown, comments are enclosed with `/*` and `*/` as open/close delimiters. Comments need to be committed, just

like other config changes.

To remove an existing comment from your current configuration, specify an empty string enclosed in double quote marks ("" ) as the comment text.

Example:

```
vyos@vyos# comment firewall all-ping "Yes I know this VyOS is cool"
vyos@vyos# commit
vyos@vyos# show
firewall {
    /* Yes I know this VyOS is cool */
    all-ping enable
    broadcast-ping disable
    ...
}
```

**Bemerkung:** An important thing to note is that since the comment is added on top of the section, it will not appear if the `show <section>` command is used. With the above example, the `show firewall` command would return starting after the `firewall {` line, hiding the comment.

### 7.1.3 Access opmode from config mode

When inside configuration mode you are not directly able to execute operational commands.

#### run

Access to these commands are possible through the use of the `run [command]` command. From this command you will have access to everything accessible from operational mode.

Command completion and syntax help with `?` and `[tab]` will also work.

```
[edit]
vyos@vyos# run show interfaces
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
eth0           0.0.0.0/0       u/u
```

### 7.1.4 Managing configurations

VyOS comes with an integrated versioning system for the system configuration. It automatically maintains a backup of every previous configuration which has been committed to the system. The configurations are versioned locally for rollback but they can also be stored on a remote host for archiving/backup reasons.

## Local Archive

Revisions are stored on disk. You can view, compare and rollback them to any previous revisions if something goes wrong.

### **show system commit**

View all existing revisions on the local system.

```
vyos@vyos:~$ show system commit
0   2015-03-30 08:53:03 by vyos via cli
1   2015-03-30 08:52:20 by vyos via cli
2   2015-03-26 21:26:01 by root via boot-config-loader
3   2015-03-26 20:43:18 by root via boot-config-loader
4   2015-03-25 11:06:14 by root via boot-config-loader
5   2015-03-25 01:04:28 by root via boot-config-loader
6   2015-03-25 00:16:47 by vyos via cli
7   2015-03-24 23:43:45 by root via boot-config-loader
```

### **set system config-management commit-revisions <N>**

You can specify the number of revisions stored on disk. N can be in the range of 0 - 65535. When the number of revisions exceeds the configured value, the oldest revision is removed. The default setting for this value is to store 100 revisions locally.

## Compare configurations

VyOS lets you compare different configurations.

### **compare <saved | N> <M>**

Use this command to spot what the differences are between different configurations.

```
vyos@vyos# compare [tab]
Possible completions:
<Enter>  Compare working & active configurations
saved    Compare working & saved configurations
<N>      Compare working with revision N
<N> <M>  Compare revision N with M
Revisions:
0        2013-12-17 20:01:37 root by boot-config-loader
1        2013-12-13 15:59:31 root by boot-config-loader
2        2013-12-12 21:56:22 vyos by cli
3        2013-12-12 21:55:11 vyos by cli
4        2013-12-12 21:27:54 vyos by cli
5        2013-12-12 21:23:29 vyos by cli
6        2013-12-12 21:13:59 root by boot-config-loader
7        2013-12-12 16:25:19 vyos by cli
8        2013-12-12 15:44:36 vyos by cli
9        2013-12-12 15:42:07 root by boot-config-loader
10       2013-12-12 15:42:06 root by init
```

The command `compare` allows you to compare different type of configurations. It also lets you compare different revisions through the `compare N M` command, where N and M are revision numbers. The output will describe how the configuration N is when compared to M indicating with a plus sign (+) the additional parts N has when compared to M, and indicating with a minus sign (-) the lacking parts N misses when compared to M.

```
vyos@vyos# compare 0 6
[edit interfaces]
+dummy dum1 {
+  address 10.189.0.1/31
+}
[edit interfaces ethernet eth0]
+vif 99 {
+  address 10.199.0.1/31
+}
-vif 900 {
-  address 192.0.2.4/24
-}
```

### **show system commit diff <number>**

Show commit revision difference.

The command above also lets you see the difference between two commits. By default the difference with the running config is shown.

```
vyos@router# run show system commit diff 4
[edit system]
+ipv6 {
+  disable-forwarding
+}
```

This means four commits ago we did set `system ipv6 disable-forwarding`.

## **Rollback Changes**

You can rollback configuration changes using the rollback command. This will apply the selected revision and trigger a system reboot.

### **rollback <N>**

Rollback to revision N (currently requires reboot)

```
vyos@vyos# compare 1
[edit system]
>host-name vyos-1
[edit]

vyos@vyos# rollback 1
Proceed with reboot? [confirm][y]
Broadcast message from root@vyos-1 (pts/0) (Tue Dec 17 21:07:45 2013):
The system is going down for reboot NOW!
```

## Remote Archive

VyOS can upload the configuration to a remote location after each call to `commit`. You will have to set the commit-archive location. TFTP, FTP, SCP and SFTP servers are supported. Every time a `commit` is successful the `config.boot` file will be copied to the defined destination(s). The filename used on the remote host will be `config.boot-hostname.YYYYMMDD_HHMMSS`.

**set system config-management commit-archive location <URI>**

Specify remote location of commit archive as any of the below URI (Uniform Resource Identifier)

- `http://<user>:<passwd>@<host>:/<dir>`
- `https://<user>:<passwd>@<host>:/<dir>`
- `ftp://<user>:<passwd>@<host>/<dir>`
- `sftp://<user>:<passwd>@<host>/<dir>`
- `scp://<user>:<passwd>@<host>:/<dir>`
- `tftp://<host>/<dir>`
- `git+https://<user>:<passwd>@<host>/<path>`

Since username and password are part of the URI, they need to be properly url encoded if containing special characters.

---

**Bemerkung:** The number of revisions don't affect the commit-archive.

---

---

**Bemerkung:** You may find VyOS not allowing the secure connection because it cannot verify the legitimacy of the remote server. You can use the workaround below to quickly add the remote host's SSH fingerprint to your `~/.ssh/known_hosts` file:

---

```
vyos@vyos# ssh-keyscan <host> >> ~/.ssh/known_hosts
```

## Saving and loading manually

You can use the `save` and `load` commands if you want to manually manage specific configuration files.

When using the `save` command, you can add a specific location where to store your configuration file. And, when needed it, you will be able to load it with the `load` command:

**load <URI>**

Use this command to load a configuration which will replace the running configuration. Define the location of the configuration file to be loaded. You can use a path to a local file, an SCP address, an SFTP address, an FTP address, an HTTP address, an HTTPS address or a TFTP address.

```
vyos@vyos# load
Possible completions:
<Enter>                Load from system config file
<file>                 Load from file on local machine
scp://<user>:<passwd>@<host>:/<file>  Load from file on remote machine
sftp://<user>:<passwd>@<host>/<file>  Load from file on remote machine
ftp://<user>:<passwd>@<host>/<file>   Load from file on remote machine
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

|                                                |                                  |
|------------------------------------------------|----------------------------------|
| <code>http://&lt;host&gt;/&lt;file&gt;</code>  | Load from file on remote machine |
| <code>https://&lt;host&gt;/&lt;file&gt;</code> | Load from file on remote machine |
| <code>tftp://&lt;host&gt;/&lt;file&gt;</code>  | Load from file on remote machine |

## Restore Default

In the case you want to completely delete your configuration and restore the default one, you can enter the following command in configuration mode:

```
load /opt/vyatta/etc/config.boot.default
```

You will be asked if you want to continue. If you accept, you will have to use `commit` if you want to make the changes active.

Then you may want to `save` in order to delete the saved configuration too.

---

**Bemerkung:** If you are remotely connected, you will lose your connection. You may want to copy first the config, edit it to ensure connectivity, and load the edited config.

---

The following structure represent the cli structure.

## 8.1 Container

The VyOS container implementation is based on *Podman*<<https://podman.io/>> as a daemonless container engine.

### 8.1.1 Configuration

**set container name <name> image**

Sets the image name in the hub registry

```
set container name mysql-server image mysql:8.0
```

If a registry is not specified, Docker.io will be used as the container registry unless an alternative registry is specified using **set container registry <name>** or the registry is included in the image name

```
set container name mysql-server image quay.io/mysql:8.0
```

**set container name <name> entrypoint <entrypoint>**

Override the default entrypoint from the image for a container.

**set container name <name> command <command>**

Override the default command from the image for a container.

**set container name <name> arguments <arguments>**

Set the command arguments for a container.

**set container name <name> host-name <hostname>**

Set the host name for a container.

**set container name <name> allow-host-pid**

The container and the host share the same process namespace. This means that processes running on the host are visible inside the container, and processes inside the container are visible on the host.

The command translates to „-pid host“ when the container is created.

**set container name <name> allow-host-networks**

Allow host networking in a container. The network stack of the container is not isolated from the host and will use the host IP.

The command translates to „-net host“ when the container is created.

---

**Bemerkung:** **allow-host-networks** cannot be used with **network**

---

**set container name <name> network <networkname>**

Attaches user-defined network to a container. Only one network must be specified and must already exist.

**set container name <name> network <networkname> address <address>**

Optionally set a specific static IPv4 or IPv6 address for the container. This address must be within the named network prefix.

---

**Bemerkung:** The first IP in the container network is reserved by the engine and cannot be used

---

**set container name <name> description <text>**

Set a container description

**set container name <name> environment <key> value <value>**

Add custom environment variables. Multiple environment variables are allowed. The following commands translate to „-e key=value“ when the container is created.

```
set container name mysql-server environment MYSQL_DATABASE value 'zabbix'
set container name mysql-server environment MYSQL_USER value 'zabbix'
set container name mysql-server environment MYSQL_PASSWORD value 'zabbix_pwd'
set container name mysql-server environment MYSQL_ROOT_PASSWORD value 'root_pwd'
```

**set container name <name> port <portname> source <portnumber>****set container name <name> port <portname> destination <portnumber>****set container name <name> port <portname> protocol <tcp | udp>**

Publish a port for the container.

```
set container name zabbix-web-nginx-mysql port http source 80
set container name zabbix-web-nginx-mysql port http destination 8080
set container name zabbix-web-nginx-mysql port http protocol tcp
```

**set container name <name> volume <volumename> source <path>****set container name <name> volume <volumename> destination <path>**

Mount a volume into the container

```
set container name coredns volume 'corefile' source /config/coredns/Corefile
set container name coredns volume 'corefile' destination /etc/Corefile
```

**set container name <name> volume <volumename> mode <ro | rw>**

Volume is either mounted as rw (read-write - default) or ro (read-only)

**set container name <name> uid <number>**

**set container name <name> gid <number>**

Set the User ID or Group ID of the container

**set container name <name> restart [no | on-failure | always]**

Set the restart behavior of the container.

- **no**: Do not restart containers on exit
- **on-failure**: Restart containers when they exit with a non-zero exit code, retrying indefinitely (default)
- **always**: Restart containers when they exit, regardless of status, retrying indefinitely

**set container name <name> memory <MB>**

Constrain the memory available to the container.

Default is 512 MB. Use 0 MB for unlimited memory.

**set container name <name> device <devicename> source <path>**

**set container name <name> device <devicename> destination <path>**

Add a host device to the container.

**set container name <name> capability <text>**

Set container capabilities or permissions.

- **net-admin**: Network operations (interface, firewall, routing tables)
- **net-bind-service**: Bind a socket to privileged ports (port numbers less than 1024)
- **net-raw**: Permission to create raw network sockets
- **setpcap**: Capability sets (from bounded or inherited set)
- **sys-admin**: Administration operations (quotactl, mount, sethostname, setdomainname)
- **sys-time**: Permission to set system clock

**set container name <name> label <label> value <value>**

Add metadata label for this container.

**set container name <name> disable**

Disable a container.

## Container Networks

**set container network <name>**

Creates a named container network

**set container network <name> description**

A brief description what this network is all about.

**set container network <name> prefix <ipv4|ipv6>**

Define IPv4 and/or IPv6 prefix for a given network name. Both IPv4 and IPv6 can be used in parallel.

**set container network <name> vrf <nme>**

Bind container network to a given VRF instance.

## Container Registry

**set container registry <name>**

Adds registry to list of unqualified-search-registries. By default, for any image that does not include the registry in the image name, VyOS will use docker.io and quay.io as the container registry.

**set container registry <name> disable**

Disable a given container registry

**set container registry <name> authentication username**

**set container registry <name> authentication password**

Some container registries require credentials to be used.

Credentials can be defined here and will only be used when adding a container image to the system.

## 8.1.2 Operation Commands

**add container image <containername>**

Pull a new image for container

**show container**

Show the list of all active containers.

**show container image**

Show the local container images.

**show container log <containername>**

Show logs from a given container

**show container network**

Show a list available container networks

**restart container <containername>**

Restart a given container

**update container image <containername>**

Update container image

**delete container image [image id|all]**

Delete a particular container image based on its image ID. You can also delete all container images at once.

**8.1.3 Example Configuration**

For the sake of demonstration, [example #1 in the official documentation](#) to the declarative VyOS CLI syntax.

```
set container network zabbix prefix 172.20.0.0/16
set container network zabbix description 'Network for Zabbix component_
↳ containers'

set container name mysql-server image mysql:8.0
set container name mysql-server network zabbix

set container name mysql-server environment 'MYSQL_DATABASE' value 'zabbix'
set container name mysql-server environment 'MYSQL_USER' value 'zabbix'
set container name mysql-server environment 'MYSQL_PASSWORD' value 'zabbix_pwd'
set container name mysql-server environment 'MYSQL_ROOT_PASSWORD' value 'root_
↳ pwd'

set container name zabbix-java-gateway image zabbix/zabbix-java-gateway:alpine-
↳ 5.2-latest
set container name zabbix-java-gateway network zabbix

set container name zabbix-server-mysql image zabbix/zabbix-server-mysql:alpine-
↳ 5.2-latest
set container name zabbix-server-mysql network zabbix

set container name zabbix-server-mysql environment 'DB_SERVER_HOST' value
↳ 'mysql-server'
set container name zabbix-server-mysql environment 'MYSQL_DATABASE' value
↳ 'zabbix'
set container name zabbix-server-mysql environment 'MYSQL_USER' value 'zabbix'
set container name zabbix-server-mysql environment 'MYSQL_PASSWORD' value
↳ 'zabbix_pwd'
set container name zabbix-server-mysql environment 'MYSQL_ROOT_PASSWORD' value
↳ 'root_pwd'
set container name zabbix-server-mysql environment 'ZBX_JAVAGATEWAY' value
↳ 'zabbix-java-gateway'

set container name zabbix-server-mysql port zabbix source 10051
set container name zabbix-server-mysql port zabbix destination 10051

set container name zabbix-web-nginx-mysql image zabbix/zabbix-web-nginx-
↳ mysql:alpine-5.2-latest
set container name zabbix-web-nginx-mysql network zabbix

set container name zabbix-web-nginx-mysql environment 'MYSQL_DATABASE' value
↳ 'zabbix'
set container name zabbix-web-nginx-mysql environment 'ZBX_SERVER_HOST' value
↳ 'zabbix-server-mysql'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set container name zabbix-web-nginx-mysql environment 'DB_SERVER_HOST' value
↪ 'mysql-server'
set container name zabbix-web-nginx-mysql environment 'MYSQL_USER' value
↪ 'zabbix'
set container name zabbix-web-nginx-mysql environment 'MYSQL_PASSWORD' value
↪ 'zabbix_pwd'
set container name zabbix-web-nginx-mysql environment 'MYSQL_ROOT_PASSWORD' ↪
↪ value 'root_pwd'

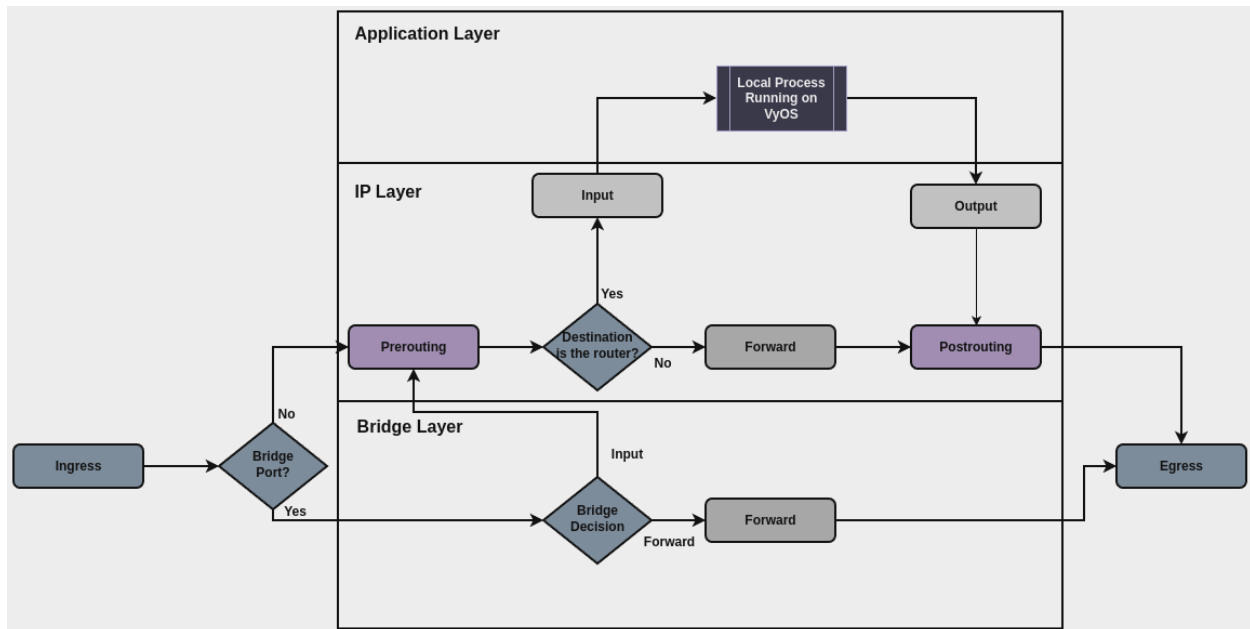

set container name zabbix-web-nginx-mysql port http source 80
set container name zabbix-web-nginx-mysql port http destination 8080

```

## 8.2 Firewall

As VyOS is based on Linux it leverages its firewall. The Netfilter project created iptables and its successor nftables for the Linux kernel to work directly on packet data flows. This now extends the concept of zone-based security to allow for manipulating the data at multiple stages once accepted by the network interface and the driver before being handed off to the destination (e.g., a web server OR another device).

A simplified traffic flow diagram, based on Netfilter packet flow, is shown next, in order to have a full view and understanding of how packets are processed, and what possible paths traffic can take.

The main points regarding this packet flow and terminology used in VyOS firewall are covered below:

- **Bridge Port?:** choose appropriate path based on whether interface where the packet was received is part of a bridge, or not.

If the interface where the packet was received isn't part of a bridge, then packet is processed at the **IP Layer**:

- **Prerouting:** several actions can be done in this stage, and currently these actions are defined in different parts in VyOS configuration. Order is important, and all these actions are performed before any actions defined under firewall section. Relevant configuration that acts in this stage are:

- **Conntrack Ignore:** rules defined under `set system conntrack ignore [ipv4 | ipv6] ....`
- **Policy Route:** rules defined under `set policy [route | route6] ....`
- **Destination NAT:** rules defined under `set [nat | nat66] destination....`
- **Destination is the router?:** choose appropriate path based on destination IP address. Transit forward continues to **forward**, while traffic that destination IP address is configured on the router continues to **input**.
- **Input:** stage where traffic destined for the router itself can be filtered and controlled. This is where all rules for securing the router should take place. This includes ipv4 and ipv6 filtering rules, defined in:
  - `set firewall ipv4 input filter ....`
  - `set firewall ipv6 input filter ....`
- **Forward:** stage where transit traffic can be filtered and controlled. This includes ipv4 and ipv6 filtering rules, defined in:
  - `set firewall ipv4 forward filter ....`
  - `set firewall ipv6 forward filter ....`
- **Output:** stage where traffic that originates from the router itself can be filtered and controlled. Bear in mind that this traffic can be a new connection originated by a internal process running on VyOS router, such as NTP, or a response to traffic received externally through **input** (for example response to an ssh login attempt to the router). This includes ipv4 and ipv6 filtering rules, defined in:
  - `set firewall ipv4 output filter ....`
  - `set firewall ipv6 output filter ....`
- **Postrouting:** as in **Prerouting**, several actions defined in different parts of VyOS configuration are performed in this stage. This includes:
  - **Source NAT:** rules defined under `set [nat | nat66] destination....`

If the interface where the packet was received is part of a bridge, then the packet is processed at the **Bridge Layer**, which contains a basic setup for bridge filtering:

- **Forward (Bridge):** stage where traffic that is trespassing through the bridge is filtered and controlled:
  - `set firewall bridge forward filter ....`

The main structure of the VyOS firewall CLI is shown next:

```
- set firewall
  * bridge
    - forward
      + filter
  * flowtable
    - custom_flow_table
      + ...
  * global-options
    + all-ping
    + broadcast-ping
    + ...
  * group
    - address-group
    - ipv6-address-group
    - network-group
    - ipv6-network-group
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

- interface-group
- mac-group
- port-group
- domain-group
* ipv4
  - forward
    + filter
  - input
    + filter
  - output
    + filter
  - name
    + custom_name
* ipv6
  - forward
    + filter
  - input
    + filter
  - output
    + filter
  - ipv6-name
    + custom_name
* zone
  - custom_zone_name
  + ...

```

Please, refer to appropriate section for more information about firewall configuration:

## 8.2.1 Global Options Firewall Configuration

### Overview

Some firewall settings are global and have an affect on the whole system. In this section there's useful information about these global-options that can be configured using vyos cli.

Configuration commands covered in this section:

```
set firewall global-options ...
```

### Configuration

```
set firewall global-options all-ping [enable | disable]
```

By default, when VyOS receives an ICMP echo request packet destined for itself, it will answer with an ICMP echo reply, unless you avoid it through its firewall.

With the firewall you can set rules to accept, drop or reject ICMP in, out or local traffic. You can also use the general **firewall all-ping** command. This command affects only to LOCAL (packets destined for your VyOS system), not to IN or OUT traffic.

---

**Bemerkung:** **firewall global-options all-ping** affects only to LOCAL and it always behaves in the most restrictive way

---

```
set firewall global-options all-ping enable
```

When the command above is set, VyOS will answer every ICMP echo request addressed to itself, but that will only happen if no other rule is applied dropping or rejecting local echo requests. In case of conflict, VyOS will not answer ICMP echo requests.

```
set firewall global-options all-ping disable
```

When the command above is set, VyOS will answer no ICMP echo request addressed to itself at all, no matter where it comes from or whether more specific rules are being applied to accept them.

**set firewall global-options broadcast-ping [enable | disable]**

This setting enable or disable the response of icmp broadcast messages. The following system parameter will be altered:

- net.ipv4.icmp\_echo\_ignore\_broadcasts

**set firewall global-options ip-src-route [enable | disable]**

**set firewall global-options ipv6-src-route [enable | disable]**

This setting handle if VyOS accept packets with a source route option. The following system parameter will be altered:

- net.ipv4.conf.all.accept\_source\_route
- net.ipv6.conf.all.accept\_source\_route

**set firewall global-options receive-redirects [enable | disable]**

**set firewall global-options ipv6-receive-redirects [enable | disable]**

enable or disable of ICMPv4 or ICMPv6 redirect messages accepted by VyOS. The following system parameter will be altered:

- net.ipv4.conf.all.accept\_redirects
- net.ipv6.conf.all.accept\_redirects

**set firewall global-options send-redirects [enable | disable]**

enable or disable ICMPv4 redirect messages send by VyOS The following system parameter will be altered:

- net.ipv4.conf.all.send\_redirects

**set firewall global-options log-martians [enable | disable]**

enable or disable the logging of martian IPv4 packets. The following system parameter will be altered:

- net.ipv4.conf.all.log\_martians

**set firewall global-options source-validation [strict | loose | disable]**

Set the IPv4 source validation mode. The following system parameter will be altered:

- net.ipv4.conf.all.rp\_filter

**set firewall global-options syn-cookies [enable | disable]**

Enable or Disable if VyOS use IPv4 TCP SYN Cookies. The following system parameter will be altered:

- net.ipv4.tcp\_syncookies

**set firewall global-options twa-hazards-protection [enable | disable]**

Enable or Disable VyOS to be [RFC 1337](#) conform. The following system parameter will be altered:

- net.ipv4.tcp\_rfc1337

```
set firewall global-options state-policy established action [accept | drop | reject]
set firewall global-options state-policy established log
set firewall global-options state-policy established log-level [emerg | alert | crit |
err | warn | notice | info | debug]
```

Set the global setting for an established connection.

```
set firewall global-options state-policy invalid action [accept | drop | reject]
set firewall global-options state-policy invalid log
set firewall global-options state-policy invalid log-level [emerg | alert | crit | err |
warn | notice | info | debug]
```

Set the global setting for invalid packets.

```
set firewall global-options state-policy related action [accept | drop | reject]
set firewall global-options state-policy related log
set firewall global-options state-policy related log-level [emerg | alert | crit | err |
warn | notice | info | debug]
```

Set the global setting for related connections.

## 8.2.2 Firewall groups

### Configuration

Firewall groups represent collections of IP addresses, networks, ports, mac addresses, domains or interfaces. Once created, a group can be referenced by firewall, nat and policy route rules as either a source or destination matcher, and/or as inbound/outbound in the case of interface group.

### Address Groups

In an **address group** a single IP address or IP address ranges are defined.

```
set firewall group address-group <name> address [address | address range]
set firewall group ipv6-address-group <name> address <address>
```

Define a IPv4 or a IPv6 address group

```
set firewall group address-group ADR-INSIDE-v4 address 192.168.0.1
set firewall group address-group ADR-INSIDE-v4 address 10.0.0.1-10.0.0.8
set firewall group ipv6-address-group ADR-INSIDE-v6 address 2001:db8::1
```

```
set firewall group address-group <name> description <text>
set firewall group ipv6-address-group <name> description <text>
```

Provide a IPv4 or IPv6 address group description

## Network Groups

While **network groups** accept IP networks in CIDR notation, specific IP addresses can be added as a 32-bit prefix. If you foresee the need to add a mix of addresses and networks, the network group is recommended.

```
set firewall group network-group <name> network <CIDR>
```

```
set firewall group ipv6-network-group <name> network <CIDR>
```

Define a IPv4 or IPv6 Network group.

```
set firewall group network-group NET-INSIDE-v4 network 192.168.0.0/24
set firewall group network-group NET-INSIDE-v4 network 192.168.1.0/24
set firewall group ipv6-network-group NET-INSIDE-v6 network 2001:db8::/64
```

```
set firewall group network-group <name> description <text>
```

```
set firewall group ipv6-network-group <name> description <text>
```

Provide an IPv4 or IPv6 network group description.

## Interface Groups

An **interface group** represents a collection of interfaces.

```
set firewall group interface-group <name> interface <text>
```

Define an interface group. Wildcard are accepted too.

```
set firewall group interface-group LAN interface bond1001
set firewall group interface-group LAN interface eth3*
```

```
set firewall group interface-group <name> description <text>
```

Provide an interface group description

## Port Groups

A **port group** represents only port numbers, not the protocol. Port groups can be referenced for either TCP or UDP. It is recommended that TCP and UDP groups are created separately to avoid accidentally filtering unnecessary ports. Ranges of ports can be specified by using -.

```
set firewall group port-group <name> port [portname | portnumber | startport-endport]
```

Define a port group. A port name can be any name defined in /etc/services. e.g.: http

```
set firewall group port-group PORT-TCP-SERVER1 port http
set firewall group port-group PORT-TCP-SERVER1 port 443
set firewall group port-group PORT-TCP-SERVER1 port 5000-5010
```

```
set firewall group port-group <name> description <text>
```

Provide a port group description.

## MAC Groups

A **mac group** represents a collection of mac addresses.

```
set firewall group mac-group <name> mac-address <mac-address>
```

Define a mac group.

```
set firewall group mac-group MAC-G01 mac-address 88:a4:c2:15:b6:4f
set firewall group mac-group MAC-G01 mac-address 4c:d5:77:c0:19:81
```

```
set firewall group mac-group <name> description <text>
```

Provide a mac group description.

## Domain Groups

A **domain group** represents a collection of domains.

```
set firewall group domain-group <name> address <domain>
```

Define a domain group.

```
set firewall group domain-group DOM address example.com
```

```
set firewall group domain-group <name> description <text>
```

Provide a domain group description.

## Dynamic Groups

Firewall dynamic groups are different from all the groups defined previously because, not only they can be used as source/destination in firewall rules, but members of these groups are not defined statically using vyos configuration.

Instead, members of these groups are added dynamically using firewall rules.

## Defining Dynamic Address Groups

Dynamic address group is supported by both IPv4 and IPv6 families. Commands used to define dynamic IPv4|IPv6 address groups are:

```
set firewall group dynamic-group address-group <name>
```

```
set firewall group dynamic-group ipv6-address-group <name>
```

Add description to firewall groups:

```
set firewall group dynamic-group address-group <name> description <text>
```

```
set firewall group dynamic-group ipv6-address-group <name> description <text>
```

## Adding elements to Dynamic Firewall Groups

Once dynamic firewall groups are defined, they should be used in firewall rules in order to dynamically add elements to it.

Commands used for this task are:

- Add destination IP address of the connection to a dynamic address group:

```
set firewall ipv4 [forward | input | output] filter rule <1-999999> add-address-to-group
destination-address address-group <name>
```

```
set firewall ipv4 name <name> rule <1-999999> add-address-to-group destination-address
address-group <name>
```

```
set firewall ipv6 [forward | input | output] filter rule <1-999999> add-address-to-group
destination-address address-group <name>
```

```
set firewall ipv6 name <name> rule <1-999999> add-address-to-group destination-address
address-group <name>
```

- Add source IP address of the connection to a dynamic address group:

```
set firewall ipv4 [forward | input | output] filter rule <1-999999> add-address-to-group
source-address address-group <name>
```

```
set firewall ipv4 name <name> rule <1-999999> add-address-to-group source-address
address-group <name>
```

```
set firewall ipv6 [forward | input | output] filter rule <1-999999> add-address-to-group
source-address address-group <name>
```

```
set firewall ipv6 name <name> rule <1-999999> add-address-to-group source-address
address-group <name>
```

Also, specific timeout can be defined per rule. In case rule gets a hit, source or destination address will be added to the group, and this element will remain in the group until timeout expires. If no timeout is defined, then the element will remain in the group until next reboot, or until a new commit that changes firewall configuration is done.

```
set firewall ipv4 [forward | input | output] filter rule <1-999999> add-address-to-group
[destination-address | source-address] timeout <timeout>
```

```
set firewall ipv4 name <name> rule <1-999999> add-address-to-group [destination-address |
source-address] timeout <timeout>
```

```
set firewall ipv6 [forward | input | output] filter rule <1-999999> add-address-to-group
[destination-address | source-address] timeout <timeout>
```

```
set firewall ipv6 name <name> rule <1-999999> add-address-to-group [destination-address |
source-address] timeout <timeout>
```

Timeout can be defined using seconds, minutes, hours or days:

```
set firewall ipv6 name F00 rule 10 add-address-to-group source-address timeout
```

Possible completions:

|           |                          |
|-----------|--------------------------|
| <number>s | Timeout value in seconds |
| <number>m | Timeout value in minutes |
| <number>h | Timeout value in hours   |
| <number>d | Timeout value in days    |

## Using Dynamic Firewall Groups

As any other firewall group, dynamic firewall groups can be used in firewall rules as matching options. For example:

### Examples

#### General example

As said before, once firewall groups are created, they can be referenced either in firewall, nat, nat66 and/or policy-route rules.

Here is an example where multiple groups are created:

```
set firewall group address-group SERVERS address 198.51.100.101
set firewall group address-group SERVERS address 198.51.100.102
set firewall group network-group TRUSTEDv4 network 192.0.2.0/30
set firewall group network-group TRUSTEDv4 network 203.0.113.128/25
set firewall group ipv6-network-group TRUSTEDv6 network 2001:db8::/64
set firewall group interface-group LAN interface eth2.2001
set firewall group interface-group LAN interface bon0
set firewall group port-group PORT-SERVERS port http
set firewall group port-group PORT-SERVERS port 443
set firewall group port-group PORT-SERVERS port 5000-5010
```

And next, some configuration example where groups are used:

```
set firewall ipv4 output filter rule 10 action accept
set firewall ipv4 output filter rule 10 outbound-interface group !LAN
set firewall ipv4 forward filter rule 20 action accept
set firewall ipv4 forward filter rule 20 source group network-group TRUSTEDv4
set firewall ipv6 input filter rule 10 action accept
set firewall ipv6 input filter rule 10 source group network-group TRUSTEDv6
set nat destination rule 101 inbound-interface group LAN
set nat destination rule 101 destination group address-group SERVERS
set nat destination rule 101 protocol tcp
set nat destination rule 101 destination group port-group PORT-SERVERS
set nat destination rule 101 translation address 203.0.113.250
set policy route PBR rule 201 destination group port-group PORT-SERVERS
set policy route PBR rule 201 protocol tcp
set policy route PBR rule 201 set table 15
```

#### Port knocking example

Using dynamic firewall groups, we can secure access to the router, or any other device if needed, by using the technique of port knocking.

A 4 step port knocking example is shown next:

```
set firewall global-options state-policy established action 'accept'
set firewall global-options state-policy invalid action 'drop'
set firewall global-options state-policy related action 'accept'
set firewall group dynamic-group address-group ALLOWED
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set firewall group dynamic-group address-group PN_01
set firewall group dynamic-group address-group PN_02
set firewall ipv4 input filter default-action 'drop'
set firewall ipv4 input filter rule 5 action 'accept'
set firewall ipv4 input filter rule 5 protocol 'icmp'
set firewall ipv4 input filter rule 10 action 'drop'
set firewall ipv4 input filter rule 10 add-address-to-group source-address_
↪address-group 'PN_01'
set firewall ipv4 input filter rule 10 add-address-to-group source-address_
↪timeout '2m'
set firewall ipv4 input filter rule 10 description 'Port_nock 01'
set firewall ipv4 input filter rule 10 destination port '9990'
set firewall ipv4 input filter rule 10 protocol 'tcp'
set firewall ipv4 input filter rule 20 action 'drop'
set firewall ipv4 input filter rule 20 add-address-to-group source-address_
↪address-group 'PN_02'
set firewall ipv4 input filter rule 20 add-address-to-group source-address_
↪timeout '3m'
set firewall ipv4 input filter rule 20 description 'Port_nock 02'
set firewall ipv4 input filter rule 20 destination port '9991'
set firewall ipv4 input filter rule 20 protocol 'tcp'
set firewall ipv4 input filter rule 20 source group dynamic-address-group 'PN_
↪01'
set firewall ipv4 input filter rule 30 action 'drop'
set firewall ipv4 input filter rule 30 add-address-to-group source-address_
↪address-group 'ALLOWED'
set firewall ipv4 input filter rule 30 add-address-to-group source-address_
↪timeout '2h'
set firewall ipv4 input filter rule 30 description 'Port_nock 03'
set firewall ipv4 input filter rule 30 destination port '9992'
set firewall ipv4 input filter rule 30 protocol 'tcp'
set firewall ipv4 input filter rule 30 source group dynamic-address-group 'PN_
↪02'
set firewall ipv4 input filter rule 99 action 'accept'
set firewall ipv4 input filter rule 99 description 'Port_nock 04 - Allow ssh'
set firewall ipv4 input filter rule 99 destination port '22'
set firewall ipv4 input filter rule 99 protocol 'tcp'
set firewall ipv4 input filter rule 99 source group dynamic-address-group
↪'ALLOWED'

```

Before testing, we can check members of firewall groups:

```

vyos@vyos# run show firewall group
Firewall Groups

```

| Name      | Type                   | References           | Members | Timeout |
|-----------|------------------------|----------------------|---------|---------|
| ↪ Expires |                        |                      |         |         |
| ↪ -----   |                        |                      |         |         |
| ALLOWED   | address_group(dynamic) | ipv4-input-filter-30 | N/D     | N/D     |
| ↪ N/D     |                        |                      |         |         |
| PN_01     | address_group(dynamic) | ipv4-input-filter-10 | N/D     | N/D     |

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

→ N/D
PN_02    address_group(dynamic)  ipv4-input-filter-20  N/D          N/D
→ N/D
[edit]
vyos@vyos#

```

With this configuration, in order to get ssh access to the router, user needs to:

1. Generate a new TCP connection with destination port 9990. As shown next, a new entry was added to dynamic firewall group **PN\_01**

```

vyos@vyos# run show firewall group
Firewall Groups

Name      Type                References          Members          Timeout
→ Expires
-----
→ -----
ALLOWED   address_group(dynamic)  ipv4-input-filter-30  N/D              N/D
→ N/D
PN_01     address_group(dynamic)  ipv4-input-filter-10  192.168.89.31    120
→ 119
PN_02     address_group(dynamic)  ipv4-input-filter-20  N/D              N/D
→ N/D
[edit]
vyos@vyos#

```

2. Generate a new TCP connection with destination port 9991. As shown next, a new entry was added to dynamic firewall group **PN\_02**

```

vyos@vyos# run show firewall group
Firewall Groups

Name      Type                References          Members          Timeout
→ Expires
-----
→ -----
ALLOWED   address_group(dynamic)  ipv4-input-filter-30  N/D              N/D
→ N/D
PN_01     address_group(dynamic)  ipv4-input-filter-10  192.168.89.31    120
→ 106
PN_02     address_group(dynamic)  ipv4-input-filter-20  192.168.89.31    180
→ 179
[edit]
vyos@vyos#

```

3. Generate a new TCP connection with destination port 9992. As shown next, a new entry was added to dynamic firewall group **ALLOWED**

```

vyos@vyos# run show firewall group
Firewall Groups

Name      Type                References          Members          Timeout

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

→ Expires
-----
→ -----
ALLOWED address_group(dynamic) ipv4-input-filter-30 192.168.89.31
→ 7200 7199
PN_01 address_group(dynamic) ipv4-input-filter-10 192.168.89.31
→ 120 89
PN_02 address_group(dynamic) ipv4-input-filter-20 192.168.89.31
→ 180 170
[edit]
vyos@vyos#

```

4. Now user can connect through ssh to the router (assuming ssh is configured).

## Operation-mode

**show firewall group**

**show firewall group <name>**

Overview of defined groups. You see the firewall group name, type, references (where the group is used), members, timeout and expiration (last two only present in dynamic firewall groups).

Here is an example of such command:

```

vyos@vyos:~$ show firewall group
Firewall Groups

Name      Type      References      Members
→ Timeout Expires
-----
→ -----
SERVERS    address_group    nat-destination-101    198.51.100.101
198.51.100.102
ALLOWED    address_group(dynamic)    ipv4-input-filter-30    192.168.77.39
→ 7200 7174
PN_01      address_group(dynamic)    ipv4-input-filter-10    192.168.0.245
→ 120 112
192.168.77.39
→ 120 85
PN_02      address_group(dynamic)    ipv4-input-filter-20    192.168.77.39
→ 180 151
LAN        interface_group    ipv4-output-filter-10    bon0
nat-destination-101    eth2.2001
TRUSTEDv6  ipv6_network_group    ipv6-input-filter-10    2001:db8::/64
TRUSTEDv4  network_group    ipv4-forward-filter-20    192.0.2.0/30
203.0.113.128/25
PORT-SERVERS    port_group    route-PBR-201    443
route-PBR-201    5000-5010
nat-destination-101    http
vyos@vyos:~$

```

## 8.2.3 Bridge Firewall Configuration

**Bemerkung:** Documentation under development

### Overview

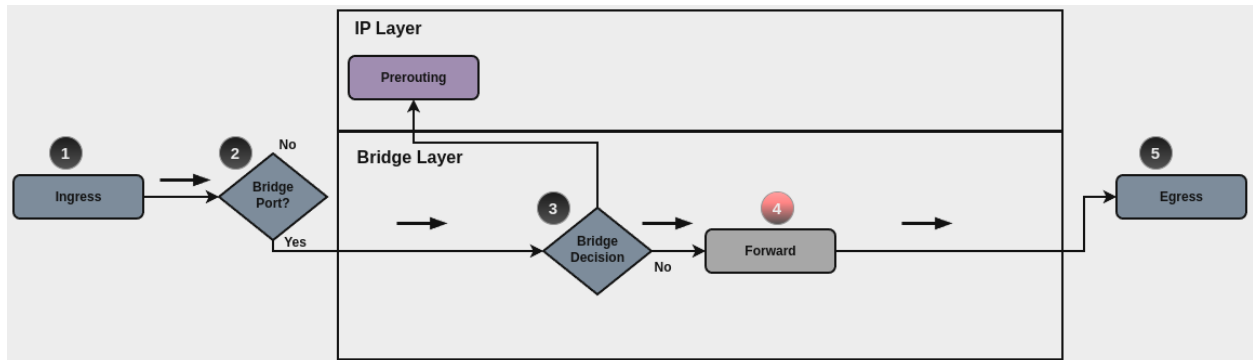

In this section there's useful information of all firewall configuration that can be done regarding bridge, and appropriate op-mode commands. Configuration commands covered in this section:

**set firewall bridge ...**

From main structure defined in *Firewall Overview* in this section you can find detailed information only for the next part of the general structure:

```
- set firewall
  * bridge
    - forward
      + filter
    - name
      + custom_name
```

Traffic which is received by the router on an interface which is member of a bridge is processed on the **Bridge Layer**. A simplified packet flow diagram for this layer is shown next:

For traffic that needs to be forwarded internally by the bridge, base chain is is **forward**, and it's base command for filtering is `set firewall bridge forward filter ...`, which happens in stage 4, highlighted with red color.

Custom bridge firewall chains can be create with command `set firewall bridge name <name> ...`. In order to use such custom chain, a rule with action jump, and the appropriate target should be defined in a base chain.

**Bemerkung: Layer 3 bridge:** When an IP address is assigned to the bridge interface, and if traffic is sent to the router to this IP (for example using such IP as default gateway), then rules defined for **bridge firewall** won't match, and firewall analysis continues at **IP layer**.

## Bridge Rules

For firewall filtering, firewall rules need to be created. Each rule is numbered, has an action to apply if the rule is matched, and the ability to specify multiple criteria matchers. Data packets go through the rules from 1 - 999999, so order is crucial. At the first match the action of the rule will be executed.

## Actions

If a rule is defined, then an action must be defined for it. This tells the firewall what to do if all criteria matchers defined for such rule do match.

In firewall bridge rules, the action can be:

- **accept**: accept the packet.
- **continue**: continue parsing next rule.
- **drop**: drop the packet.
- **jump**: jump to another custom chain.
- **return**: Return from the current chain and continue at the next rule of the last chain.
- **queue**: Enqueue packet to userspace.

```
set firewall bridge forward filter rule <1-999999> action [accept | continue | drop |
jump | queue | return]
```

```
set firewall bridge name <name> rule <1-999999> action [accept | continue | drop | jump |
queue | return]
```

This required setting defines the action of the current rule. If action is set to **jump**, then **jump-target** is also needed.

```
set firewall bridge forward filter rule <1-999999> jump-target <text>
```

```
set firewall bridge name <name> rule <1-999999> jump-target <text>
```

```
set firewall bridge forward filter rule <1-999999> queue <0-65535>
```

```
set firewall bridge name <name> rule <1-999999> queue <0-65535>
```

To be used only when action is set to **queue**. Use this command to specify queue target to use. Queue range is also supported.

```
set firewall bridge forward filter rule <1-999999> queue-options bypass
```

```
set firewall bridge name <name> rule <1-999999> queue-options bypass
```

To be used only when action is set to **queue**. Use this command to let packet go through firewall when no userspace software is connected to the queue.

```
set firewall bridge forward filter rule <1-999999> queue-options fanout
```

```
set firewall bridge name <name> rule <1-999999> queue-options fanout
```

To be used only when action is set to **queue**. Use this command to distribute packets between several queues.

Also, **default-action** is an action that takes place whenever a packet does not match any rule in its chain. For base chains, possible options for **default-action** are **accept** or **drop**.

```
set firewall bridge forward filter default-action [accept | drop]
```

```
set firewall bridge name <name> default-action [accept | continue | drop | jump | queue |
return]
```

This set the default action of the rule-set if no rule matched a packet criteria. If default-action is set to `jump`, then `default-jump-target` is also needed. Note that for base chains, default action can only be set to `accept` or `drop`, while on custom chain, more actions are available.

```
set firewall bridge name <name> default-jump-target <text>
```

To be used only when `default-action` is set to `jump`. Use this command to specify jump target for default rule.

---

**Bemerkung: Important note about default-actions:** If default action for any base chain is not defined, then the default action is set to `accept` for that chain. For custom chains, if default action is not defined, then the default-action is set to `drop`.

---

## Firewall Logs

Logging can be enable for every single firewall rule. If enabled, other log options can be defined.

```
set firewall bridge forward filter rule <1-999999> log
```

```
set firewall bridge name <name> rule <1-999999> log
```

Enable logging for the matched packet. If this configuration command is not present, then log is not enabled.

```
set firewall bridge forward filter default-log
```

```
set firewall bridge name <name> default-log
```

Use this command to enable the logging of the default action on the specified chain.

```
set firewall bridge forward filter rule <1-999999> log-options level [emerg | alert |  
crit | err | warn | notice | info | debug]
```

```
set firewall bridge name <name> rule <1-999999> log-options level [emerg | alert | crit |  
err | warn | notice | info | debug]
```

Define log-level. Only applicable if rule log is enable.

```
set firewall bridge forward filter rule <1-999999> log-options group <0-65535>
```

```
set firewall bridge name <name> rule <1-999999> log-options group <0-65535>
```

Define log group to send message to. Only applicable if rule log is enable.

```
set firewall bridge forward filter rule <1-999999> log-options snapshot-length <0-9000>
```

```
set firewall bridge name <name> rule <1-999999> log-options snapshot-length <0-9000>
```

Define length of packet payload to include in netlink message. Only applicable if rule log is enable and log group is defined.

```
set firewall bridge forward filter rule <1-999999> log-options queue-threshold <0-65535>
```

```
set firewall bridge name <name> rule <1-999999> log-options queue-threshold <0-65535>
```

Define number of packets to queue inside the kernel before sending them to userspace. Only applicable if rule log is enable and log group is defined.

## Firewall Description

For reference, a description can be defined for every defined custom chain.

```
set firewall bridge name <name> description <text>
```

Provide a rule-set description to a custom firewall chain.

## Rule Status

When defining a rule, it is enable by default. In some cases, it is useful to just disable the rule, rather than removing it.

```
set firewall bridge forward filter rule <1-999999> disable
```

```
set firewall bridge name <name> rule <1-999999> disable
```

Command for disabling a rule but keep it in the configuration.

## Matching criteria

There are a lot of matching criteria against which the packet can be tested.

```
set firewall bridge forward filter rule <1-999999> destination mac-address <mac-address>
```

```
set firewall bridge name <name> rule <1-999999> destination mac-address <mac-address>
```

```
set firewall bridge forward filter rule <1-999999> source mac-address <mac-address>
```

```
set firewall bridge name <name> rule <1-999999> source mac-address <mac-address>
```

Match criteria based on source and/or destination mac-address.

```
set firewall bridge forward filter rule <1-999999> inbound-interface name <iface>
```

```
set firewall bridge name <name> rule <1-999999> inbound-interface name <iface>
```

Match based on inbound interface. Wildcard \* can be used. For example: eth2\*. Prepending character ! for inverted matching criteria is also supported. For example !eth2

```
set firewall bridge forward filter rule <1-999999> inbound-interface group <iface_group>
```

```
set firewall bridge name <name> rule <1-999999> inbound-interface group <iface_group>
```

Match based on inbound interface group. Prepending character ! for inverted matching criteria is also supported. For example !IFACE\_GROUP

```
set firewall bridge forward filter rule <1-999999> outbound-interface name <iface>
```

```
set firewall bridge name <name> rule <1-999999> outbound-interface name <iface>
```

Match based on outbound interface. Wildcard \* can be used. For example: eth2\*. Prepending character ! for inverted matching criteria is also supported. For example !eth2

```
set firewall bridge forward filter rule <1-999999> outbound-interface group <iface_group>
```

```
set firewall bridge name <name> rule <1-999999> outbound-interface group <iface_group>
```

Match based on outbound interface group. Prepending character ! for inverted matching criteria is also supported. For example !IFACE\_GROUP

```
set firewall bridge forward filter rule <1-999999> vlan id <0-4096>
```

```
set firewall bridge name <name> rule <1-999999> vlan id <0-4096>
```

Match based on vlan ID. Range is also supported.

```
set firewall bridge forward filter rule <1-999999> vlan priority <0-7>
set firewall bridge name <name> rule <1-999999> vlan priority <0-7>
```

Match based on vlan priority(pcp). Range is also supported.

## Operation-mode Firewall

### Rule-set overview

In this section you can find all useful firewall op-mode commands.

General commands for firewall configuration, counter and statistics:

```
show firewall
show firewall summary
show firewall statistics
```

And, to print only bridge firewall information:

```
show firewall bridge
show firewall bridge forward filter
show firewall bridge forward filter rule <rule>
show firewall bridge name <name>
show firewall bridge name <name> rule <rule>
```

### Show Firewall log

```
show log firewall
show log firewall bridge
show log firewall bridge forward
show log firewall bridge forward filter
show log firewall bridge name <name>
show log firewall bridge forward filter rule <rule>
show log firewall bridge name <name> rule <rule>
```

Show the logs of all firewall; show all bridge firewall logs; show all logs for forward hook; show all logs for forward hook and priority filter; show all logs for particular custom chain; show logs for specific Rule-Set.

## Example

Configuration example:

```
set firewall bridge forward filter default-action 'drop'
set firewall bridge forward filter default-log
set firewall bridge forward filter rule 10 action 'continue'
set firewall bridge forward filter rule 10 inbound-interface name 'eth2'
set firewall bridge forward filter rule 10 vlan id '22'
set firewall bridge forward filter rule 20 action 'drop'
set firewall bridge forward filter rule 20 inbound-interface group 'TRUNK-RIGHT'
set firewall bridge forward filter rule 20 vlan id '60'
set firewall bridge forward filter rule 30 action 'jump'
set firewall bridge forward filter rule 30 jump-target 'TEST'
set firewall bridge forward filter rule 30 outbound-interface name '!eth1'
set firewall bridge forward filter rule 35 action 'accept'
set firewall bridge forward filter rule 35 vlan id '11'
set firewall bridge forward filter rule 40 action 'continue'
set firewall bridge forward filter rule 40 destination mac-address '66:55:44:33:22:11'
set firewall bridge forward filter rule 40 source mac-address '11:22:33:44:55:66'
set firewall bridge name TEST default-action 'accept'
set firewall bridge name TEST default-log
set firewall bridge name TEST rule 10 action 'continue'
set firewall bridge name TEST rule 10 log
set firewall bridge name TEST rule 10 vlan priority '0'
```

And op-mode commands:

```
vyos@BRI:~$ show firewall bridge
Rulesets bridge Information

-----
bridge Firewall "forward filter"

Rule      Action    Protocol  Packets   Bytes    Conditions
-----
10        continue  all       0         0        iifname "eth2" vlan id 22  continue
20        drop      all       0         0        iifname @I_TRUNK-RIGHT vlan id 60
30        jump      all       2130      170688   oifname != "eth1"  jump NAME_TEST
35        accept    all       2080      168616   vlan id 11  accept
40        continue  all       0         0        ether daddr 66:55:44:33:22:11 ether_
↳saddr 11:22:33:44:55:66  continue
default   drop      all       0         0

-----
bridge Firewall "name TEST"

Rule      Action    Protocol  Packets   Bytes    Conditions
-----
10        continue  all       2130      170688   vlan pcp 0  prefix "[bri-NAM-TEST-10-
↳C]"  continue
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

default accept all 2130 170688

vyos@BRI:~$
vyos@BRI:~$ show firewall bridge name TEST
Ruleset Information

-----
bridge Firewall "name TEST"

Rule      Action    Protocol    Packets    Bytes    Conditions
-----
10        continue all          2130      170688    vlan pcp 0 prefix "[bri-NAM-TEST-10-
C]" continue
default accept all 2130 170688

vyos@BRI:~$

```

Inspect logs:

```

vyos@BRI:~$ show log firewall bridge

```

## 8.2.4 IPv4 Firewall Configuration

### Overview

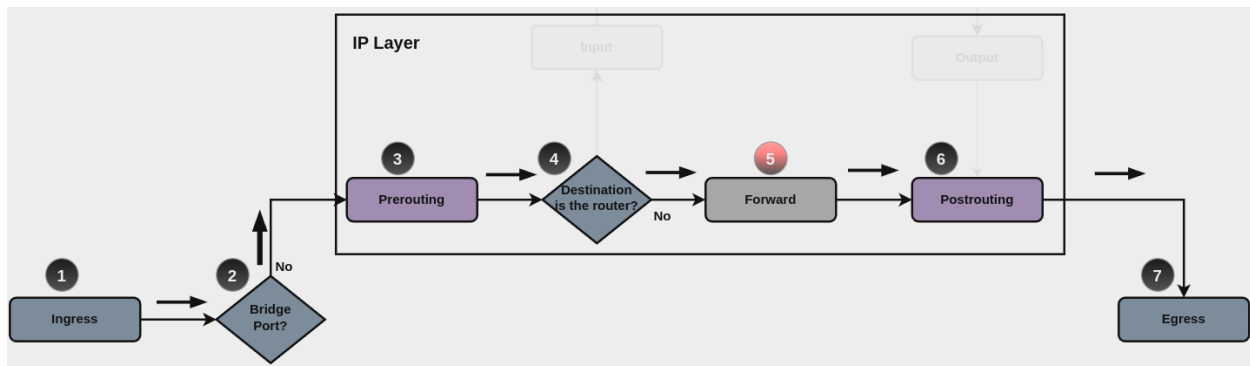

In this section there's useful information of all firewall configuration that can be done regarding IPv4, and appropriate op-mode commands. Configuration commands covered in this section:

**set firewall ipv4 ...**

From main structure defined in *Firewall Overview* in this section you can find detailed information only for the next part of the general structure:

```
- set firewall
  * ipv4
    - forward
      + filter
    - input
      + filter
    - output
      + filter
    - name
      + custom_name
```

For transit traffic, which is received by the router and forwarded, base chain is **forward**. A simplified packet flow diagram for transit traffic is shown next:

Where firewall base chain to configure firewall filtering rules for transit traffic is **set firewall ipv4 forward filter ...**, which happens in stage 5, highlighted with red color.

For traffic towards the router itself, base chain is **input**, while traffic originated by the router, base chain is **output**. A new simplified packet flow diagram is shown next, which shows the path for traffic destined to the router itself, and traffic generated by the router (starting from circle number 6):

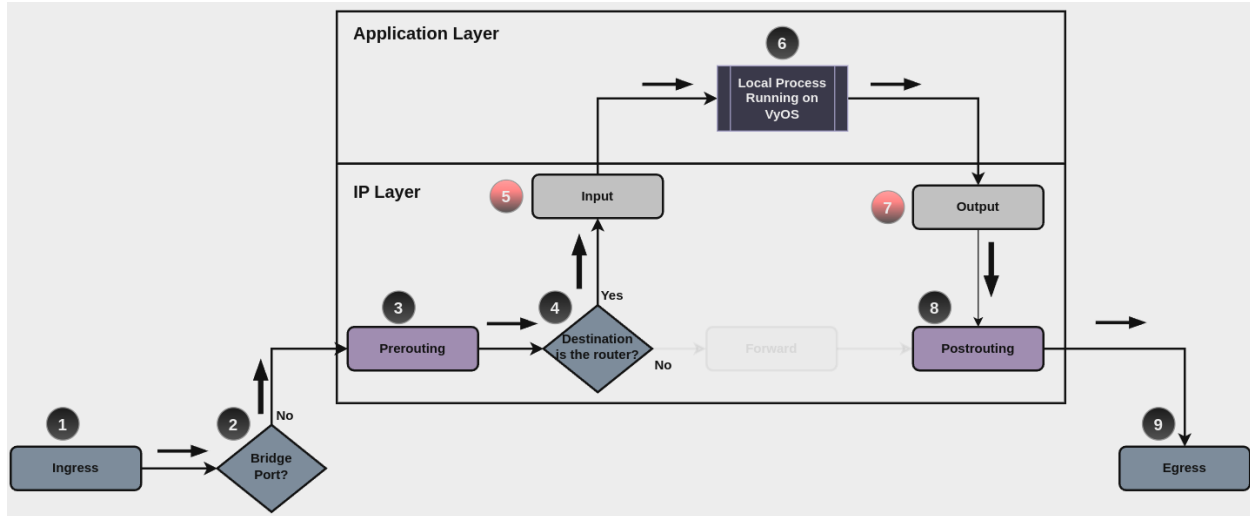

Base chain is for traffic toward the router is **set firewall ipv4 input filter ...**

And base chain for traffic generated by the router is **set firewall ipv4 output filter ...**

**Bemerkung: Important note about default-actions:** If default action for any base chain is not defined, then the default action is set to **accept** for that chain. For custom chains, if default action is not defined, then the default-action is set to **drop**

Custom firewall chains can be created, with commands **set firewall ipv4 name <name> ...**. In order to use such custom chain, a rule with **action jump**, and the appropriate **target** should be defined in a base chain.

## Firewall - IPv4 Rules

For firewall filtering, firewall rules need to be created. Each rule is numbered, has an action to apply if the rule is matched, and the ability to specify multiple criteria matchers. Data packets go through the rules from 1 - 999999, so order is crucial. At the first match the action of the rule will be executed.

## Actions

If a rule is defined, then an action must be defined for it. This tells the firewall what to do if all criteria matchers defined for such rule do match.

The action can be :

- **accept:** accept the packet.
- **continue:** continue parsing next rule.
- **drop:** drop the packet.
- **reject:** reject the packet.
- **jump:** jump to another custom chain.
- **return:** Return from the current chain and continue at the next rule of the last chain.
- **queue:** Enqueue packet to userspace.
- **synproxy:** synproxy the packet.

```
set firewall ipv4 forward filter rule <1-999999> action [accept | continue | drop | jump
| queue | reject | return | synproxy]
```

```
set firewall ipv4 input filter rule <1-999999> action [accept | continue | drop | jump |
queue | reject | return | synproxy]
```

```
set firewall ipv4 output filter rule <1-999999> action [accept | continue | drop | jump |
queue | reject | return]
```

```
set firewall ipv4 name <name> rule <1-999999> action [accept | continue | drop | jump |
queue | reject | return]
```

This required setting defines the action of the current rule. If action is set to jump, then jump-target is also needed.

```
set firewall ipv4 forward filter rule <1-999999> jump-target <text>
set firewall ipv4 input filter rule <1-999999> jump-target <text>
set firewall ipv4 output filter rule <1-999999> jump-target <text>
set firewall ipv4 name <name> rule <1-999999> jump-target <text>
```

To be used only when action is set to jump. Use this command to specify jump target.

```
set firewall ipv4 forward filter rule <1-999999> queue <0-65535>
set firewall ipv4 input filter rule <1-999999> queue <0-65535>
set firewall ipv4 output filter rule <1-999999> queue <0-65535>
set firewall ipv4 name <name> rule <1-999999> queue <0-65535>
```

To be used only when action is set to queue. Use this command to specify queue target to use. Queue range is also supported.

```
set firewall ipv4 forward filter rule <1-999999> queue-options bypass
set firewall ipv4 input filter rule <1-999999> queue-options bypass
set firewall ipv4 output filter rule <1-999999> queue-options bypass
set firewall ipv4 name <name> rule <1-999999> queue-options bypass
```

To be used only when action is set to queue. Use this command to let packet go through firewall when no userspace software is connected to the queue.

```
set firewall ipv4 forward filter rule <1-999999> queue-options fanout
set firewall ipv4 input filter rule <1-999999> queue-options fanout
set firewall ipv4 output filter rule <1-999999> queue-options fanout
set firewall ipv4 name <name> rule <1-999999> queue-options fanout
```

To be used only when action is set to queue. Use this command to distribute packets between several queues.

Also, **default-action** is an action that takes place whenever a packet does not match any rule in it's chain. For base chains, possible options for **default-action** are **accept** or **drop**.

```
set firewall ipv4 forward filter default-action [accept | drop]
set firewall ipv4 input filter default-action [accept | drop]
set firewall ipv4 output filter default-action [accept | drop]
set firewall ipv4 name <name> default-action [accept | drop | jump | queue | reject |
return]
```

This set the default action of the rule-set if no rule matched a packet criteria. If default-action is set to jump, then default-jump-target is also needed. Note that for base chains, default action can only be set to accept or drop, while on custom chain, more actions are available.

```
set firewall ipv4 name <name> default-jump-target <text>
```

To be used only when default-action is set to jump. Use this command to specify jump target for default rule.

---

**Bemerkung: Important note about default-actions:** If default action for any base chain is not defined, then the default action is set to **accept** for that chain. For custom chains, if default action is not defined, then the default-action is set to **drop**.

---

## Firewall Logs

Logging can be enable for every single firewall rule. If enabled, other log options can be defined.

```
set firewall ipv4 forward filter rule <1-999999> log
set firewall ipv4 input filter rule <1-999999> log
set firewall ipv4 output filter rule <1-999999> log
set firewall ipv4 name <name> rule <1-999999> log
```

Enable logging for the matched packet. If this configuration command is not present, then log is not enabled.

```
set firewall ipv4 forward filter default-log
set firewall ipv4 input filter default-log
set firewall ipv4 output filter default-log
set firewall ipv4 name <name> default-log
```

Use this command to enable the logging of the default action on the specified chain.

```
set firewall ipv4 forward filter rule <1-999999> log-options level [emerg | alert | crit
| err | warn | notice | info | debug]
set firewall ipv4 input filter rule <1-999999> log-options level [emerg | alert | crit |
err | warn | notice | info | debug]
set firewall ipv4 output filter rule <1-999999> log-options level [emerg | alert | crit |
err | warn | notice | info | debug]
set firewall ipv4 name <name> rule <1-999999> log-options level [emerg | alert | crit |
err | warn | notice | info | debug]
```

Define log-level. Only applicable if rule log is enable.

```
set firewall ipv4 forward filter rule <1-999999> log-options group <0-65535>
set firewall ipv4 input filter rule <1-999999> log-options group <0-65535>
set firewall ipv4 output filter rule <1-999999> log-options group <0-65535>
set firewall ipv4 name <name> rule <1-999999> log-options group <0-65535>
```

Define log group to send message to. Only applicable if rule log is enable.

```
set firewall ipv4 forward filter rule <1-999999> log-options snapshot-length <0-9000>
set firewall ipv4 input filter rule <1-999999> log-options snapshot-length <0-9000>
set firewall ipv4 output filter rule <1-999999> log-options snapshot-length <0-9000>
set firewall ipv4 name <name> rule <1-999999> log-options snapshot-length <0-9000>
```

Define length of packet payload to include in netlink message. Only applicable if rule log is enable and log group is defined.

```
set firewall ipv4 forward filter rule <1-999999> log-options queue-threshold <0-65535>
```

```
set firewall ipv4 input filter rule <1-999999> log-options queue-threshold <0-65535>
set firewall ipv4 output filter rule <1-999999> log-options queue-threshold <0-65535>
set firewall ipv4 name <name> rule <1-999999> log-options queue-threshold <0-65535>
```

Define number of packets to queue inside the kernel before sending them to userspace. Only applicable if rule log is enable and log group is defined.

## Firewall Description

For reference, a description can be defined for every single rule, and for every defined custom chain.

```
set firewall ipv4 name <name> description <text>
```

Provide a rule-set description to a custom firewall chain.

```
set firewall ipv4 forward filter rule <1-999999> description <text>
```

```
set firewall ipv4 input filter rule <1-999999> description <text>
```

```
set firewall ipv4 output filter rule <1-999999> description <text>
```

```
set firewall ipv4 name <name> rule <1-999999> description <text>
```

Provide a description for each rule.

## Rule Status

When defining a rule, it is enable by default. In some cases, it is useful to just disable the rule, rather than removing it.

```
set firewall ipv4 forward filter rule <1-999999> disable
```

```
set firewall ipv4 input filter rule <1-999999> disable
```

```
set firewall ipv4 output filter rule <1-999999> disable
```

```
set firewall ipv4 name <name> rule <1-999999> disable
```

Command for disabling a rule but keep it in the configuration.

## Matching criteria

There are a lot of matching criteria against which the packet can be tested.

```
set firewall ipv4 forward filter rule <1-999999> connection-status nat [destination |
source]
```

```
set firewall ipv4 input filter rule <1-999999> connection-status nat [destination |
source]
```

```
set firewall ipv4 output filter rule <1-999999> connection-status nat [destination |
source]
```

```
set firewall ipv4 name <name> rule <1-999999> connection-status nat [destination |
source]
```

Match criteria based on nat connection status.

```
set firewall ipv4 forward filter rule <1-999999> connection-mark <1-2147483647>
```

```
set firewall ipv4 input filter rule <1-999999> connection-mark <1-2147483647>
```

```
set firewall ipv4 output filter rule <1-999999> connection-mark <1-2147483647>
set firewall ipv4 name <name> rule <1-999999> connection-mark <1-2147483647>
```

Match criteria based on connection mark.

```
set firewall ipv4 forward filter rule <1-999999> conntrack-helper <module>
set firewall ipv4 input filter rule <1-999999> conntrack-helper <module>
set firewall ipv4 output filter rule <1-999999> conntrack-helper <module>
set firewall ipv4 name <name> rule <1-999999> conntrack-helper <module>
```

Match based on connection tracking protocol helper module to secure use of that helper module. See below for possible completions *<module>*.

Possible completions:

|        |                                    |
|--------|------------------------------------|
| ftp    | Related traffic from FTP helper    |
| h323   | Related traffic from H.323 helper  |
| pptp   | Related traffic from PPTP helper   |
| nfs    | Related traffic from NFS helper    |
| sip    | Related traffic from SIP helper    |
| tftp   | Related traffic from TFTP helper   |
| sqlnet | Related traffic from SQLNet helper |

```
set firewall ipv4 forward filter rule <1-999999> source address [address | addressrange |
CIDR]
set firewall ipv4 input filter rule <1-999999> source address [address | addressrange |
CIDR]
set firewall ipv4 output filter rule <1-999999> source address [address | addressrange |
CIDR]
set firewall ipv4 name <name> rule <1-999999> source address [address | addressrange |
CIDR]
set firewall ipv4 forward filter rule <1-999999> destination address [address |
addressrange | CIDR]
set firewall ipv4 input filter rule <1-999999> destination address [address |
addressrange | CIDR]
set firewall ipv4 output filter rule <1-999999> destination address [address |
addressrange | CIDR]
set firewall ipv4 name <name> rule <1-999999> destination address [address | addressrange
| CIDR]
```

Match criteria based on source and/or destination address. This is similar to the network groups part, but here you are able to negate the matching addresses.

```
set firewall ipv4 name F00 rule 50 source address 192.0.2.10-192.0.2.11
# with a '!' the rule match everything except the specified subnet
set firewall ipv4 input filter F00 rule 51 source address !203.0.113.0/24
```

```
set firewall ipv4 forward filter rule <1-999999> source address-mask [address]
set firewall ipv4 input filter rule <1-999999> source address-mask [address]
set firewall ipv4 output filter rule <1-999999> source address-mask [address]
```

```

set firewall ipv4 name <name> rule <1-999999> source address-mask [address]
set firewall ipv4 forward filter rule <1-999999> destination address-mask [address]
set firewall ipv4 input filter rule <1-999999> destination address-mask [address]
set firewall ipv4 output filter rule <1-999999> destination address-mask [address]
set firewall ipv4 name <name> rule <1-999999> destination address-mask [address]

```

An arbitrary netmask can be applied to mask addresses to only match against a specific portion.

This functions for both individual addresses and address groups.

```

# Match any IPv4 address with `11` as the 2nd octet and `13` as the forth octet
set firewall ipv4 name F00 rule 100 destination address 0.11.0.13
set firewall ipv4 name F00 rule 100 destination address-mask 0.255.0.255

```

```

set firewall ipv4 forward filter rule <1-999999> source fqdn <fqdn>
set firewall ipv4 input filter rule <1-999999> source fqdn <fqdn>
set firewall ipv4 output filter rule <1-999999> source fqdn <fqdn>
set firewall ipv4 name <name> rule <1-999999> source fqdn <fqdn>
set firewall ipv4 forward filter rule <1-999999> destination fqdn <fqdn>
set firewall ipv4 input filter rule <1-999999> destination fqdn <fqdn>
set firewall ipv4 output filter rule <1-999999> destination fqdn <fqdn>
set firewall ipv4 name <name> rule <1-999999> destination fqdn <fqdn>

```

Specify a Fully Qualified Domain Name as source/destination matcher. Ensure router is able to resolve such dns query.

```

set firewall ipv4 forward filter rule <1-999999> source geoip country-code <country>
set firewall ipv4 input filter rule <1-999999> source geoip country-code <country>
set firewall ipv4 output filter rule <1-999999> source geoip country-code <country>
set firewall ipv4 name <name> rule <1-999999> source geoip country-code <country>
set firewall ipv4 forward filter rule <1-999999> destination geoip country-code <country>
set firewall ipv4 input filter rule <1-999999> destination geoip country-code <country>
set firewall ipv4 output filter rule <1-999999> destination geoip country-code <country>
set firewall ipv4 name <name> rule <1-999999> destination geoip country-code <country>
set firewall ipv4 forward filter rule <1-999999> source geoip inverse-match
set firewall ipv4 input filter rule <1-999999> source geoip inverse-match
set firewall ipv4 output filter rule <1-999999> source geoip inverse-match
set firewall ipv4 name <name> rule <1-999999> source geoip inverse-match
set firewall ipv4 forward filter rule <1-999999> destination geoip inverse-match
set firewall ipv4 input filter rule <1-999999> destination geoip inverse-match
set firewall ipv4 output filter rule <1-999999> destination geoip inverse-match
set firewall ipv4 name <name> rule <1-999999> destination geoip inverse-match

```

Match IP addresses based on its geolocation. More info: [geoip matching](#). Use inverse-match to match anything except the given country-codes.

Data is provided by DB-IP.com under CC-BY-4.0 license. Attribution required, permits redistribution so we can include a database in images(~3MB compressed). Includes cron script (manually callable by op-mode update geoip) to keep database and rules updated.

```
set firewall ipv4 forward filter rule <1-999999> source mac-address <mac-address>
set firewall ipv4 input filter rule <1-999999> source mac-address <mac-address>
set firewall ipv4 output filter rule <1-999999> source mac-address <mac-address>
set firewall ipv4 name <name> rule <1-999999> source mac-address <mac-address>
```

Only in the source criteria, you can specify a mac-address.

```
set firewall ipv4 input filter rule 100 source mac-address 00:53:00:11:22:33
set firewall ipv4 input filter rule 101 source mac-address !00:53:00:aa:12:34
```

```
set firewall ipv4 forward filter rule <1-999999> source port [1-65535 | portname |
start-end]
set firewall ipv4 input filter rule <1-999999> source port [1-65535 | portname |
start-end]
set firewall ipv4 output filter rule <1-999999> source port [1-65535 | portname |
start-end]
set firewall ipv4 name <name> rule <1-999999> source port [1-65535 | portname |
start-end]
set firewall ipv4 forward filter rule <1-999999> destination port [1-65535 | portname |
start-end]
set firewall ipv4 input filter rule <1-999999> destination port [1-65535 | portname |
start-end]
set firewall ipv4 output filter rule <1-999999> destination port [1-65535 | portname |
start-end]
set firewall ipv4 name <name> rule <1-999999> destination port [1-65535 | portname |
start-end]
```

A port can be set with a port number or a name which is here defined: /etc/services.

```
set firewall ipv4 forward filter rule 10 source port '22'
set firewall ipv4 forward filter rule 11 source port '!http'
set firewall ipv4 forward filter rule 12 source port 'https'
```

Multiple source ports can be specified as a comma-separated list. The whole list can also be „negated“ using !. For example:

```
set firewall ipv4 forward filter rule <1-999999> source group address-group <name | !
name>
set firewall ipv4 input filter rule <1-999999> source group address-group <name | !name>
set firewall ipv4 output filter rule <1-999999> source group address-group <name | !name>
set firewall ipv4 name <name> rule <1-999999> source group address-group <name | !name>
set firewall ipv4 forward filter rule <1-999999> destination group address-group <name |
!name>
```

```
set firewall ipv4 input filter rule <1-999999> destination group address-group <name |
!name>
set firewall ipv4 output filter rule <1-999999> destination group address-group <name |
!name>
set firewall ipv4 name <name> rule <1-999999> destination group address-group <name |
!name>
```

Use a specific address-group. Prepend character ! for inverted matching criteria.

```
set firewall ipv4 forward filter rule <1-999999> source group dynamic-address-group <name
| !name>
set firewall ipv4 input filter rule <1-999999> source group dynamic-address-group <name |
!name>
set firewall ipv4 output filter rule <1-999999> source group dynamic-address-group <name
| !name>
set firewall ipv4 name <name> rule <1-999999> source group dynamic-address-group <name |
!name>
set firewall ipv4 forward filter rule <1-999999> destination group dynamic-address-group
<name | !name>
set firewall ipv4 input filter rule <1-999999> destination group dynamic-address-group
<name | !name>
set firewall ipv4 output filter rule <1-999999> destination group dynamic-address-group
<name | !name>
set firewall ipv4 name <name> rule <1-999999> destination group dynamic-address-group
<name | !name>
```

Use a specific dynamic-address-group. Prepend character ! for inverted matching criteria.

```
set firewall ipv4 forward filter rule <1-999999> source group network-group <name | !
name>
set firewall ipv4 input filter rule <1-999999> source group network-group <name | !name>
set firewall ipv4 output filter rule <1-999999> source group network-group <name | !name>
set firewall ipv4 name <name> rule <1-999999> source group network-group <name | !name>
set firewall ipv4 forward filter rule <1-999999> destination group network-group <name |
!name>
set firewall ipv4 input filter rule <1-999999> destination group network-group <name |
!name>
set firewall ipv4 output filter rule <1-999999> destination group network-group <name |
!name>
set firewall ipv4 name <name> rule <1-999999> destination group network-group <name |
!name>
```

Use a specific network-group. Prepend character ! for inverted matching criteria.

```
set firewall ipv4 forward filter rule <1-999999> source group port-group <name | !name>
set firewall ipv4 input filter rule <1-999999> source group port-group <name | !name>
set firewall ipv4 output filter rule <1-999999> source group port-group <name | !name>
```

```

set firewall ipv4 name <name> rule <1-999999> source group port-group <name | !name>
set firewall ipv4 forward filter rule <1-999999> destination group port-group <name | !name>
set firewall ipv4 input filter rule <1-999999> destination group port-group <name | !name>
set firewall ipv4 output filter rule <1-999999> destination group port-group <name | !name>
set firewall ipv4 name <name> rule <1-999999> destination group port-group <name | !name>

```

Use a specific port-group. Prepend character ! for inverted matching criteria.

```

set firewall ipv4 forward filter rule <1-999999> source group domain-group <name | !name>
set firewall ipv4 input filter rule <1-999999> source group domain-group <name | !name>
set firewall ipv4 output filter rule <1-999999> source group domain-group <name | !name>
set firewall ipv4 name <name> rule <1-999999> source group domain-group <name | !name>
set firewall ipv4 forward filter rule <1-999999> destination group domain-group <name | !name>
set firewall ipv4 input filter rule <1-999999> destination group domain-group <name | !name>
set firewall ipv4 output filter rule <1-999999> destination group domain-group <name | !name>
set firewall ipv4 name <name> rule <1-999999> destination group domain-group <name | !name>

```

Use a specific domain-group. Prepend character ! for inverted matching criteria.

```

set firewall ipv4 forward filter rule <1-999999> source group mac-group <name | !name>
set firewall ipv4 input filter rule <1-999999> source group mac-group <name | !name>
set firewall ipv4 output filter rule <1-999999> source group mac-group <name | !name>
set firewall ipv4 name <name> rule <1-999999> source group mac-group <name | !name>
set firewall ipv4 forward filter rule <1-999999> destination group mac-group <name | !name>
set firewall ipv4 input filter rule <1-999999> destination group mac-group <name | !name>
set firewall ipv4 output filter rule <1-999999> destination group mac-group <name | !name>
set firewall ipv4 name <name> rule <1-999999> destination group mac-group <name | !name>

```

Use a specific mac-group. Prepend character ! for inverted matching criteria.

```

set firewall ipv4 forward filter rule <1-999999> dscp [0-63 | start-end]
set firewall ipv4 input filter rule <1-999999> dscp [0-63 | start-end]
set firewall ipv4 output filter rule <1-999999> dscp [0-63 | start-end]
set firewall ipv4 name <name> rule <1-999999> dscp [0-63 | start-end]
set firewall ipv4 forward filter rule <1-999999> dscp-exclude [0-63 | start-end]
set firewall ipv4 input filter rule <1-999999> dscp-exclude [0-63 | start-end]

```

```
set firewall ipv4 output filter rule <1-999999> dscp-exclude [0-63 | start-end]
set firewall ipv4 name <name> rule <1-999999> dscp-exclude [0-63 | start-end]
```

Match based on dscp value.

```
set firewall ipv4 forward filter rule <1-999999> fragment [match-frag | match-non-frag]
set firewall ipv4 input filter rule <1-999999> fragment [match-frag | match-non-frag]
set firewall ipv4 output filter rule <1-999999> fragment [match-frag | match-non-frag]
set firewall ipv4 name <name> rule <1-999999> fragment [match-frag | match-non-frag]
```

Match based on fragment criteria.

```
set firewall ipv4 forward filter rule <1-999999> icmp [code | type] <0-255>
set firewall ipv4 input filter rule <1-999999> icmp [code | type] <0-255>
set firewall ipv4 output filter rule <1-999999> icmp [code | type] <0-255>
set firewall ipv4 name <name> rule <1-999999> icmp [code | type] <0-255>
```

Match based on icmp code and type.

```
set firewall ipv4 forward filter rule <1-999999> icmp type-name <text>
set firewall ipv4 input filter rule <1-999999> icmp type-name <text>
set firewall ipv4 output filter rule <1-999999> icmp type-name <text>
set firewall ipv4 name <name> rule <1-999999> icmp type-name <text>
```

Match based on icmp type-name criteria. Use tab for information about what **type-name** criteria are supported.

```
set firewall ipv4 forward filter rule <1-999999> inbound-interface name <iface>
set firewall ipv4 input filter rule <1-999999> inbound-interface name <iface>
set firewall ipv4 name <name> rule <1-999999> inbound-interface name <iface>
```

Match based on inbound interface. Wildcard \* can be used. For example: eth2\*. Prepending character ! for inverted matching criteria is also supported. For example !eth2

```
set firewall ipv4 forward filter rule <1-999999> inbound-interface group <iface_group>
set firewall ipv4 input filter rule <1-999999> inbound-interface group <iface_group>
set firewall ipv4 name <name> rule <1-999999> inbound-interface group <iface_group>
```

Match based on inbound interface group. Prepending character ! for inverted matching criteria is also supported. For example !IFACE\_GROUP

```
set firewall ipv4 forward filter rule <1-999999> outbound-interface name <iface>
set firewall ipv4 output filter rule <1-999999> outbound-interface name <iface>
set firewall ipv4 name <name> rule <1-999999> outbound-interface name <iface>
```

Match based on outbound interface. Wildcard \* can be used. For example: eth2\*. Prepending character ! for inverted matching criteria is also supported. For example !eth2

```
set firewall ipv4 forward filter rule <1-999999> outbound-interface group <iface_group>
set firewall ipv4 output filter rule <1-999999> outbound-interface group <iface_group>
set firewall ipv4 name <name> rule <1-999999> outbound-interface group <iface_group>
```

Match based on outbound interface group. Prepending character ! for inverted matching criteria is also supported. For example !IFACE\_GROUP

```
set firewall ipv4 forward filter rule <1-999999> ipsec [match-ipsec | match-none]
set firewall ipv4 input filter rule <1-999999> ipsec [match-ipsec | match-none]
set firewall ipv4 output filter rule <1-999999> ipsec [match-ipsec | match-none]
set firewall ipv4 name <name> rule <1-999999> ipsec [match-ipsec | match-none]
```

Match based on ipsec criteria.

```
set firewall ipv4 forward filter rule <1-999999> limit burst <0-4294967295>
set firewall ipv4 input filter rule <1-999999> limit burst <0-4294967295>
set firewall ipv4 output filter rule <1-999999> limit burst <0-4294967295>
set firewall ipv4 name <name> rule <1-999999> limit burst <0-4294967295>
```

Match based on the maximum number of packets to allow in excess of rate.

```
set firewall ipv4 forward filter rule <1-999999> limit rate <text>
set firewall ipv4 input filter rule <1-999999> limit rate <text>
set firewall ipv4 output filter rule <1-999999> limit rate <text>
set firewall ipv4 name <name> rule <1-999999> limit rate <text>
```

Match based on the maximum average rate, specified as **integer/unit**. For example 5/minutes

```
set firewall ipv4 forward filter rule <1-999999> packet-length <text>
set firewall ipv4 input filter rule <1-999999> packet-length <text>
set firewall ipv4 output filter rule <1-999999> packet-length <text>
set firewall ipv4 name <name> rule <1-999999> packet-length <text>
set firewall ipv4 forward filter rule <1-999999> packet-length-exclude <text>
set firewall ipv4 input filter rule <1-999999> packet-length-exclude <text>
set firewall ipv4 output filter rule <1-999999> packet-length-exclude <text>
set firewall ipv4 name <name> rule <1-999999> packet-length-exclude <text>
```

Match based on packet length criteria. Multiple values from 1 to 65535 and ranges are supported.

```
set firewall ipv4 forward filter rule <1-999999> packet-type [broadcast | host |
multicast | other]
set firewall ipv4 input filter rule <1-999999> packet-type [broadcast | host | multicast
| other]
set firewall ipv4 output filter rule <1-999999> packet-type [broadcast | host | multicast
| other]
set firewall ipv4 name <name> rule <1-999999> packet-type [broadcast | host | multicast |
other]
```

Match based on packet type criteria.

```
set firewall ipv4 forward filter rule <1-999999> protocol [<text> | <0-255> | all |
tcp_udp]
```

```
set firewall ipv4 input filter rule <1-999999> protocol [<text> | <0-255> | all |
tcp_udp]
set firewall ipv4 output filter rule <1-999999> protocol [<text> | <0-255> | all |
tcp_udp]
set firewall ipv4 name <name> rule <1-999999> protocol [<text> | <0-255> | all | tcp_udp]
```

Match a protocol criteria. A protocol number or a name which is here defined: /etc/protocols. Special names are all for all protocols and tcp\_udp for tcp and udp based packets. The ! negate the selected protocol.

```
set firewall ipv4 forward filter rule 10 protocol tcp_udp
set firewall ipv4 forward filter rule 11 protocol !tcp_udp
```

```
set firewall ipv4 forward filter rule <1-999999> recent count <1-255>
set firewall ipv4 input filter rule <1-999999> recent count <1-255>
set firewall ipv4 output filter rule <1-999999> recent count <1-255>
set firewall ipv4 name <name> rule <1-999999> recent count <1-255>
set firewall ipv4 forward filter rule <1-999999> recent time [second | minute | hour]
set firewall ipv4 input filter rule <1-999999> recent time [second | minute | hour]
set firewall ipv4 output filter rule <1-999999> recent time [second | minute | hour]
set firewall ipv4 name <name> rule <1-999999> recent time [second | minute | hour]
```

Match bases on recently seen sources.

```
set firewall ipv4 forward filter rule <1-999999> tcp flags [not] <text>
set firewall ipv4 input filter rule <1-999999> tcp flags [not] <text>
set firewall ipv4 output filter rule <1-999999> tcp flags [not] <text>
set firewall ipv4 name <name> rule <1-999999> tcp flags [not] <text>
```

Allowed values for TCP flags: ack, cwr, ecn, fin, psh, rst, syn and urg. Multiple values are supported, and for inverted selection use not, as shown in the example.

```
set firewall ipv4 input filter rule 10 tcp flags 'ack'
set firewall ipv4 input filter rule 12 tcp flags 'syn'
set firewall ipv4 input filter rule 13 tcp flags not 'fin'
```

```
set firewall ipv4 forward filter rule <1-999999> state [established | invalid | new |
related]
set firewall ipv4 input filter rule <1-999999> state [established | invalid | new |
related]
set firewall ipv4 output filter rule <1-999999> state [established | invalid | new |
related]
set firewall ipv4 name <name> rule <1-999999> state [established | invalid | new |
related]
```

Match against the state of a packet.

```
set firewall ipv4 forward filter rule <1-999999> time startdate <text>
set firewall ipv4 input filter rule <1-999999> time startdate <text>
set firewall ipv4 output filter rule <1-999999> time startdate <text>
```

```

set firewall ipv4 name <name> rule <1-999999> time startdate <text>
set firewall ipv4 forward filter rule <1-999999> time starttime <text>
set firewall ipv4 input filter rule <1-999999> time starttime <text>
set firewall ipv4 output filter rule <1-999999> time starttime <text>
set firewall ipv4 name <name> rule <1-999999> time starttime <text>
set firewall ipv4 forward filter rule <1-999999> time stopdate <text>
set firewall ipv4 input filter rule <1-999999> time stopdate <text>
set firewall ipv4 output filter rule <1-999999> time stopdate <text>
set firewall ipv4 name <name> rule <1-999999> time stopdate <text>
set firewall ipv4 forward filter rule <1-999999> time stoptime <text>
set firewall ipv4 input filter rule <1-999999> time stoptime <text>
set firewall ipv4 output filter rule <1-999999> time stoptime <text>
set firewall ipv4 name <name> rule <1-999999> time stoptime <text>
set firewall ipv4 forward filter rule <1-999999> time weekdays <text>
set firewall ipv4 input filter rule <1-999999> time weekdays <text>
set firewall ipv4 output filter rule <1-999999> time weekdays <text>
set firewall ipv4 name <name> rule <1-999999> time weekdays <text>

```

Time to match the defined rule.

```

set firewall ipv4 forward filter rule <1-999999> ttl <eq | gt | lt> <0-255>
set firewall ipv4 input filter rule <1-999999> ttl <eq | gt | lt> <0-255>
set firewall ipv4 output filter rule <1-999999> ttl <eq | gt | lt> <0-255>
set firewall ipv4 name <name> rule <1-999999> ttl <eq | gt | lt> <0-255>

```

Match time to live parameter, where ,eq' stands for ,equal'; ,gt' stands for ,greater than', and ,lt' stands for ,less than'.

```

set firewall ipv4 forward filter rule <1-999999> recent count <1-255>
set firewall ipv4 input filter rule <1-999999> recent count <1-255>
set firewall ipv4 output filter rule <1-999999> recent count <1-255>
set firewall ipv4 name <name> rule <1-999999> recent count <1-255>
set firewall ipv4 forward filter rule <1-999999> recent time <second | minute | hour>
set firewall ipv4 input filter rule <1-999999> recent time <second | minute | hour>
set firewall ipv4 output filter rule <1-999999> recent time <second | minute | hour>
set firewall ipv4 name <name> rule <1-999999> recent time <second | minute | hour>

```

Match when ,count' amount of connections are seen within ,time'. These matching criteria can be used to block brute-force attempts.

## Synproxy

Synproxy connections

```
set firewall ipv4 [input | forward] filter rule <1-999999> action synproxy
set firewall ipv4 [input | forward] filter rule <1-999999> protocol tcp
set firewall ipv4 [input | forward] filter rule <1-999999> synproxy tcp mss <501-65535>
```

Set TCP-MSS (maximum segment size) for the connection

```
set firewall ipv4 [input | forward] filter rule <1-999999> synproxy tcp window-scale <1-14>
```

Set the window scale factor for TCP window scaling

## Example synproxy

Requirements to enable synproxy:

- Traffic must be symmetric
- Synproxy relies on syncookies and TCP timestamps, ensure these are enabled
- Disable conntrack loose track option

```
set system sysctl parameter net.ipv4.tcp_timestamps value '1'

set system conntrack tcp loose disable
set system conntrack ignore ipv4 rule 10 destination port '8080'
set system conntrack ignore ipv4 rule 10 protocol 'tcp'
set system conntrack ignore ipv4 rule 10 tcp flags syn

set firewall global-options syn-cookies 'enable'
set firewall ipv4 input filter rule 10 action 'synproxy'
set firewall ipv4 input filter rule 10 destination port '8080'
set firewall ipv4 input filter rule 10 inbound-interface name 'eth1'
set firewall ipv4 input filter rule 10 protocol 'tcp'
set firewall ipv4 input filter rule 10 synproxy tcp mss '1460'
set firewall ipv4 input filter rule 10 synproxy tcp window-scale '7'
set firewall ipv4 input filter rule 1000 action 'drop'
set firewall ipv4 input filter rule 1000 state invalid
```

## Operation-mode Firewall

### Rule-set overview

#### show firewall

This will show you a basic firewall overview, for all ruleset, and not only for ipv4

```
vyos@vyos:~$ show firewall
Rulesets Information
```

```
-----
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

ipv4 Firewall "forward filter"

Rule      Action    Protocol    Packets    Bytes    Conditions
-----
20        accept    all         0           0        ip saddr @N_TRUSTEDv4  accept
21        jump      all         0           0        jump NAME_AUX
default   accept    all         0           0

-----

ipv4 Firewall "input filter"

→ "eth2"

-----

ipv4 Firewall "output filter"

Rule      Action    Protocol    Packets    Bytes    Conditions
-----
→ 10      reject    all          0           0        oifname @I_LAN
20        accept    icmp         2          168      meta l4proto icmp oifname "eth0"
→ accept
default   accept    all         72          9258

-----

ipv6 Firewall "input filter"

Rule      Action    Protocol    Packets    Bytes    Conditions
-----
10        accept    all         0           0        ip6 saddr @N6_TRUSTEDv6  accept
default   accept    all         2          112

vyos@vyos:~$

```

**show firewall summary**

This will show you a summary of rule-sets and groups

```
vyos@vyos:~$ show firewall summary
```

#### Ruleset Summary

##### IPv6 Ruleset:

| Ruleset Hook | Ruleset Priority     | Description     |
|--------------|----------------------|-----------------|
| forward      | filter               |                 |
| input        | filter               |                 |
| ipv6_name    | IPV6-VyOS_MANAGEMENT |                 |
| ipv6_name    | IPV6-WAN_IN          | PUBLIC_INTERNET |

##### IPv4 Ruleset:

| Ruleset Hook | Ruleset Priority | Description     |
|--------------|------------------|-----------------|
| forward      | filter           |                 |
| input        | filter           |                 |
| name         | VyOS_MANAGEMENT  |                 |
| name         | WAN_IN           | PUBLIC_INTERNET |

#### Firewall Groups

| Name               | Type               | References              | Members       |
|--------------------|--------------------|-------------------------|---------------|
| ↔ --               |                    |                         |               |
| PBX                | address_group      | WAN_IN-100              | 198.51.100.77 |
| SERVERS            | address_group      | WAN_IN-110              | 192.0.2.10    |
|                    |                    | WAN_IN-111              | 192.0.2.11    |
|                    |                    | WAN_IN-112              | 192.0.2.12    |
|                    |                    | WAN_IN-120              |               |
|                    |                    | WAN_IN-121              |               |
|                    |                    | WAN_IN-122              |               |
| SUPPORT            | address_group      | VyOS_MANAGEMENT-20      | 192.168.1.2   |

|                    |                    | IPV6-WAN_IN-122         |               |
| SUPPORT            | ipv6_address_group | IPV6-VyOS_MANAGEMENT-20 | 2001:db8::5   |
|                    |                    | IPV6-WAN_IN-20          |               |

```
show firewall ipv4 [forward | input | output] filter
```

```
show firewall ipv4 name <name>
```

This command will give an overview of a single rule-set.

```
vyos@vyos:~$ show firewall ipv4 input filter
Ruleset Information

-----
IPv4 Firewall "input filter"

Rule      Action    Protocol    Packets    Bytes    Conditions
-----
5         jump      all         0          0        iifname "eth2"  jump NAME_VyOS_
MANAGEMENT
default   accept    all
```

**show firewall ipv4 [forward | input | output] filter rule <1-999999>**

**show firewall ipv4 name <name> rule <1-999999>**

This command will give an overview of a rule in a single rule-set, plus information for default action.

```
vyos@vyos:~$ show firewall ipv4 output filter rule 20
Rule Information

-----
ipv4 Firewall "output filter"

Rule      Action    Protocol    Packets    Bytes    Conditions
-----
20        accept    icmp         2          168      meta l4proto icmp oifname "eth0"
accept
default   accept    all         286        47614
```

**show firewall statistics**

This will show you a statistic of all rule-sets since the last boot.

## Show Firewall log

**show log firewall**

**show log firewall ipv4**

**show log firewall ipv4 [forward | input | output | name]**

**show log firewall ipv4 [forward | input | output] filter**

**show log firewall ipv4 name <name>**

**show log firewall ipv4 [forward | input | output] filter rule <rule>**

**show log firewall ipv4 name <name> rule <rule>**

Show the logs of all firewall; show all ipv4 firewall logs; show all logs for particular hook; show all logs for particular hook and priority; show all logs for particular custom chain; show logs for specific Rule-Set.

### Example Partial Config

```
firewall {
  group {
    network-group BAD-NETWORKS {
      network 198.51.100.0/24
      network 203.0.113.0/24
    }
    network-group GOOD-NETWORKS {
      network 192.0.2.0/24
    }
    port-group BAD-PORTS {
      port 65535
    }
  }
  ipv4 {
    forward {
      filter {
        default-action accept
        rule 5 {
          action accept
          source {
            group {
              network-group GOOD-NETWORKS
            }
          }
        }
        rule 10 {
          action drop
          description "Bad Networks"
          protocol all
          source {
            group {
              network-group BAD-NETWORKS
            }
          }
        }
      }
    }
  }
}
```

## Update geoip database

### update geoip

Command used to update GeoIP database and firewall sets.

## 8.2.5 IPv6 Firewall Configuration

### Overview

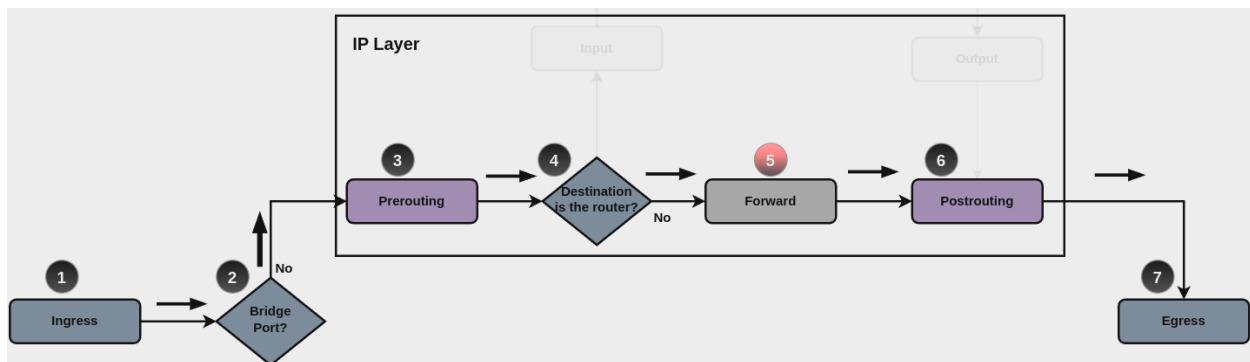

In this section there's useful information of all firewall configuration that can be done regarding IPv6, and appropriate op-mode commands. Configuration commands covered in this section:

#### set firewall ipv6 ...

From main structure defined in *Firewall Overview* in this section you can find detailed information only for the next part of the general structure:

```
- set firewall
  * ipv6
    - forward
      + filter
    - input
      + filter
    - output
      + filter
    - name
      + custom_name
```

For transit traffic, which is received by the router and forwarded, base chain is **forward**. A simplified packet flow diagram for transit traffic is shown next:

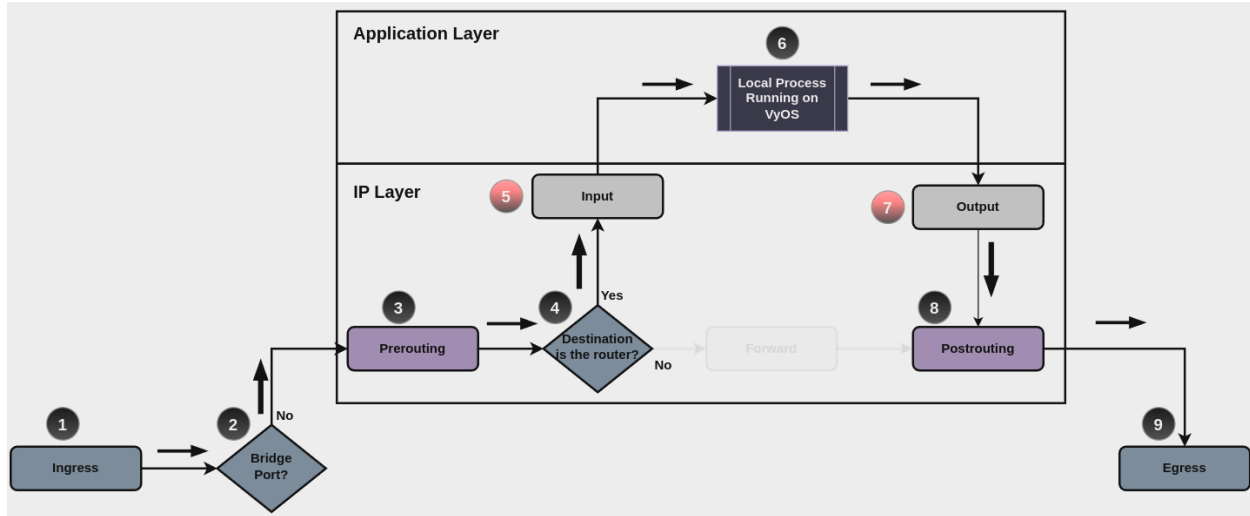

Where firewall base chain to configure firewall filtering rules for transit traffic is `set firewall ipv6 forward filter ...`, which happens in stage 5, highlighted with red color.

For traffic towards the router itself, base chain is **input**, while traffic originated by the router, base chain is **output**. A new simplified packet flow diagram is shown next, which shows the path for traffic destined to the router itself, and traffic generated by the router (starting from circle number 6):

Base chain is for traffic toward the router is `set firewall ipv6 input filter ...`

And base chain for traffic generated by the router is `set firewall ipv6 output filter ...`

**Bemerkung: Important note about default-actions:** If default action for any base chain is not defined, then the default action is set to **accept** for that chain. For custom chains, if default action is not defined, then the default-action is set to **drop**

Custom firewall chains can be created, with commands `set firewall ipv6 name <name> ...`. In order to use such custom chain, a rule with **action jump**, and the appropriate **target** should be defined in a base chain.

## Firewall - IPv6 Rules

For firewall filtering, firewall rules need to be created. Each rule is numbered, has an action to apply if the rule is matched, and the ability to specify multiple criteria matchers. Data packets go through the rules from 1 - 999999, so order is crucial. At the first match the action of the rule will be executed.

## Actions

If a rule is defined, then an action must be defined for it. This tells the firewall what to do if all criteria matchers defined for such rule do match.

The action can be :

- **accept:** accept the packet.
- **continue:** continue parsing next rule.
- **drop:** drop the packet.
- **reject:** reject the packet.
- **jump:** jump to another custom chain.
- **return:** Return from the current chain and continue at the next rule of the last chain.
- **queue:** Enqueue packet to userspace.
- **synproxy:** synproxy the packet.

```
set firewall ipv6 forward filter rule <1-999999> action [accept | continue | drop | jump
| queue | reject | return | synproxy]
```

```
set firewall ipv6 input filter rule <1-999999> action [accept | continue | drop | jump |
queue | reject | return | synproxy]
set firewall ipv6 output filter rule <1-999999> action [accept | continue | drop | jump |
queue | reject | return]
set firewall ipv6 name <name> rule <1-999999> action [accept | continue | drop | jump |
queue | reject | return]
```

This required setting defines the action of the current rule. If action is set to jump, then jump-target is also needed.

```
set firewall ipv6 forward filter rule <1-999999> jump-target <text>
set firewall ipv6 input filter rule <1-999999> jump-target <text>
set firewall ipv6 output filter rule <1-999999> jump-target <text>
set firewall ipv6 name <name> rule <1-999999> jump-target <text>
```

To be used only when action is set to jump. Use this command to specify jump target.

```
set firewall ipv6 forward filter rule <1-999999> queue <0-65535>
set firewall ipv6 input filter rule <1-999999> queue <0-65535>
set firewall ipv6 output filter rule <1-999999> queue <0-65535>
set firewall ipv6 name <name> rule <1-999999> queue <0-65535>
```

To be used only when action is set to queue. Use this command to specify queue target to use. Queue range is also supported.

```
set firewall ipv6 forward filter rule <1-999999> queue-options bypass
set firewall ipv6 input filter rule <1-999999> queue-options bypass
set firewall ipv6 output filter rule <1-999999> queue-options bypass
set firewall ipv6 name <name> rule <1-999999> queue-options bypass
```

To be used only when action is set to queue. Use this command to let packet go through firewall when no userspace software is connected to the queue.

```
set firewall ipv6 forward filter rule <1-999999> queue-options fanout
set firewall ipv6 input filter rule <1-999999> queue-options fanout
set firewall ipv6 output filter rule <1-999999> queue-options fanout
set firewall ipv6 name <name> rule <1-999999> queue-options fanout
```

To be used only when action is set to queue. Use this command to distribute packets between several queues.

Also, **default-action** is an action that takes place whenever a packet does not match any rule in it's chain. For base chains, possible options for **default-action** are **accept** or **drop**.

```
set firewall ipv6 forward filter default-action [accept | drop]
set firewall ipv6 input filter default-action [accept | drop]
set firewall ipv6 output filter default-action [accept | drop]
set firewall ipv6 name <name> default-action [accept | drop | jump | queue | reject |
return]
```

This set the default action of the rule-set if no rule matched a packet criteria. If default-action is set to `jump`, then `default-jump-target` is also needed. Note that for base chains, default action can only be set to `accept` or `drop`, while on custom chain, more actions are available.

```
set firewall ipv6 name <name> default-jump-target <text>
```

To be used only when `default-action` is set to `jump`. Use this command to specify jump target for default rule.

---

**Bemerkung: Important note about default-actions:** If default action for any base chain is not defined, then the default action is set to `accept` for that chain. For custom chains, if default action is not defined, then the default-action is set to `drop`.

---

## Firewall Logs

Logging can be enable for every single firewall rule. If enabled, other log options can be defined.

```
set firewall ipv6 forward filter rule <1-999999> log
set firewall ipv6 input filter rule <1-999999> log
set firewall ipv6 output filter rule <1-999999> log
set firewall ipv6 name <name> rule <1-999999> log
```

Enable logging for the matched packet. If this configuration command is not present, then log is not enabled.

```
set firewall ipv6 forward filter default-log
set firewall ipv6 input filter default-log
set firewall ipv6 output filter default-log
set firewall ipv6 name <name> default-log
```

Use this command to enable the logging of the default action on the specified chain.

```
set firewall ipv6 forward filter rule <1-999999> log-options level [emerg | alert | crit
| err | warn | notice | info | debug]
set firewall ipv6 input filter rule <1-999999> log-options level [emerg | alert | crit |
err | warn | notice | info | debug]
set firewall ipv6 output filter rule <1-999999> log-options level [emerg | alert | crit |
err | warn | notice | info | debug]
set firewall ipv6 name <name> rule <1-999999> log-options level [emerg | alert | crit |
err | warn | notice | info | debug]
```

Define log-level. Only applicable if rule log is enable.

```
set firewall ipv6 forward filter rule <1-999999> log-options group <0-65535>
set firewall ipv6 input filter rule <1-999999> log-options group <0-65535>
set firewall ipv6 output filter rule <1-999999> log-options group <0-65535>
set firewall ipv6 name <name> rule <1-999999> log-options group <0-65535>
```

Define log group to send message to. Only applicable if rule log is enable.

```
set firewall ipv6 forward filter rule <1-999999> log-options snapshot-length <0-9000>
```

```
set firewall ipv6 input filter rule <1-999999> log-options snapshot-length <0-9000>
set firewall ipv6 output filter rule <1-999999> log-options snapshot-length <0-9000>
set firewall ipv6 name <name> rule <1-999999> log-options snapshot-length <0-9000>
```

Define length of packet payload to include in netlink message. Only applicable if rule log is enable and log group is defined.

```
set firewall ipv6 forward filter rule <1-999999> log-options queue-threshold <0-65535>
set firewall ipv6 input filter rule <1-999999> log-options queue-threshold <0-65535>
set firewall ipv6 output filter rule <1-999999> log-options queue-threshold <0-65535>
set firewall ipv6 name <name> rule <1-999999> log-options queue-threshold <0-65535>
```

Define number of packets to queue inside the kernel before sending them to userspace. Only applicable if rule log is enable and log group is defined.

## Firewall Description

For reference, a description can be defined for every single rule, and for every defined custom chain.

```
set firewall ipv6 name <name> description <text>
```

Provide a rule-set description to a custom firewall chain.

```
set firewall ipv6 forward filter rule <1-999999> description <text>
set firewall ipv6 input filter rule <1-999999> description <text>
set firewall ipv6 output filter rule <1-999999> description <text>
set firewall ipv6 name <name> rule <1-999999> description <text>
```

Provide a description for each rule.

## Rule Status

When defining a rule, it is enable by default. In some cases, it is useful to just disable the rule, rather than removing it.

```
set firewall ipv6 forward filter rule <1-999999> disable
set firewall ipv6 input filter rule <1-999999> disable
set firewall ipv6 output filter rule <1-999999> disable
set firewall ipv6 name <name> rule <1-999999> disable
```

Command for disabling a rule but keep it in the configuration.

## Matching criteria

There are a lot of matching criteria against which the packet can be tested.

```
set firewall ipv6 forward filter rule <1-999999> connection-status nat [destination | source]
```

```
set firewall ipv6 input filter rule <1-999999> connection-status nat [destination | source]
```

```
set firewall ipv6 output filter rule <1-999999> connection-status nat [destination | source]
```

```
set firewall ipv6 name <name> rule <1-999999> connection-status nat [destination | source]
```

Match criteria based on nat connection status.

```
set firewall ipv6 forward filter rule <1-999999> connection-mark <1-2147483647>
```

```
set firewall ipv6 input filter rule <1-999999> connection-mark <1-2147483647>
```

```
set firewall ipv6 output filter rule <1-999999> connection-mark <1-2147483647>
```

```
set firewall ipv6 name <name> rule <1-999999> connection-mark <1-2147483647>
```

Match criteria based on connection mark.

```
set firewall ipv6 forward filter rule <1-999999> source address [address | addressrange | CIDR]
```

```
set firewall ipv6 input filter rule <1-999999> source address [address | addressrange | CIDR]
```

```
set firewall ipv6 output filter rule <1-999999> source address [address | addressrange | CIDR]
```

```
set firewall ipv6 name <name> rule <1-999999> source address [address | addressrange | CIDR]
```

```
set firewall ipv6 forward filter rule <1-999999> destination address [address | addressrange | CIDR]
```

```
set firewall ipv6 input filter rule <1-999999> destination address [address | addressrange | CIDR]
```

```
set firewall ipv6 output filter rule <1-999999> destination address [address | addressrange | CIDR]
```

```
set firewall ipv6 name <name> rule <1-999999> destination address [address | addressrange | CIDR]
```

Match criteria based on source and/or destination address. This is similar to the network groups part, but here you are able to negate the matching addresses.

```
set firewall ipv6 name F00 rule 100 source address 2001:db8::202
```

```
set firewall ipv6 forward filter rule <1-999999> source address-mask [address]
```

```
set firewall ipv6 input filter rule <1-999999> source address-mask [address]
```

```
set firewall ipv6 output filter rule <1-999999> source address-mask [address]
```

```
set firewall ipv6 name <name> rule <1-999999> source address-mask [address]
```

```

set firewall ipv6 forward filter rule <1-999999> destination address-mask [address]
set firewall ipv6 input filter rule <1-999999> destination address-mask [address]
set firewall ipv6 output filter rule <1-999999> destination address-mask [address]
set firewall ipv6 name <name> rule <1-999999> destination address-mask [address]

```

An arbitrary netmask can be applied to mask addresses to only match against a specific portion. This is particularly useful with IPv6 as rules will remain valid if the IPv6 prefix changes and the host portion of systems IPv6 address is static (for example, with SLAAC or [tokenised IPv6 addresses](#))

This functions for both individual addresses and address groups.

```

# Match any IPv6 address with the suffix ::0000:0000:0000:beef
set firewall ipv6 forward filter rule 100 destination address ::beef
set firewall ipv6 forward filter rule 100 destination address-mask
↪ ::ffff:ffff:ffff:ffff
# Address groups
set firewall group ipv6-address-group WEBSERVERS address ::1000
set firewall group ipv6-address-group WEBSERVERS address ::2000
set firewall ipv6 forward filter rule 200 source group address-group WEBSERVERS
set firewall ipv6 forward filter rule 200 source address-mask ::ffff:ffff:ffff:ffff

```

```

set firewall ipv6 forward filter rule <1-999999> source fqdn <fqdn>
set firewall ipv6 input filter rule <1-999999> source fqdn <fqdn>
set firewall ipv6 output filter rule <1-999999> source fqdn <fqdn>
set firewall ipv6 name <name> rule <1-999999> source fqdn <fqdn>
set firewall ipv6 forward filter rule <1-999999> destination fqdn <fqdn>
set firewall ipv6 input filter rule <1-999999> destination fqdn <fqdn>
set firewall ipv6 output filter rule <1-999999> destination fqdn <fqdn>
set firewall ipv6 name <name> rule <1-999999> destination fqdn <fqdn>

```

Specify a Fully Qualified Domain Name as source/destination matcher. Ensure router is able to resolve such dns query.

```

set firewall ipv6 forward filter rule <1-999999> source geoip country-code <country>
set firewall ipv6 input filter rule <1-999999> source geoip country-code <country>
set firewall ipv6 output filter rule <1-999999> source geoip country-code <country>
set firewall ipv6 name <name> rule <1-999999> source geoip country-code <country>
set firewall ipv6 forward filter rule <1-999999> destination geoip country-code <country>
set firewall ipv6 input filter rule <1-999999> destination geoip country-code <country>
set firewall ipv6 output filter rule <1-999999> destination geoip country-code <country>
set firewall ipv6 name <name> rule <1-999999> destination geoip country-code <country>
set firewall ipv6 forward filter rule <1-999999> source geoip inverse-match
set firewall ipv6 input filter rule <1-999999> source geoip inverse-match
set firewall ipv6 output filter rule <1-999999> source geoip inverse-match
set firewall ipv6 name <name> rule <1-999999> source geoip inverse-match

```

```
set firewall ipv6 forward filter rule <1-999999> destination geoip inverse-match
set firewall ipv6 input filter rule <1-999999> destination geoip inverse-match
set firewall ipv6 output filter rule <1-999999> destination geoip inverse-match
set firewall ipv6 name <name> rule <1-999999> destination geoip inverse-match
```

Match IP addresses based on its geolocation. More info: [geoip matching](#). Use inverse-match to match anything except the given country-codes.

Data is provided by DB-IP.com under CC-BY-4.0 license. Attribution required, permits redistribution so we can include a database in images(~3MB compressed). Includes cron script (manually callable by op-mode update geoip) to keep database and rules updated.

```
set firewall ipv6 forward filter rule <1-999999> source mac-address <mac-address>
set firewall ipv6 input filter rule <1-999999> source mac-address <mac-address>
set firewall ipv6 output filter rule <1-999999> source mac-address <mac-address>
set firewall ipv6 name <name> rule <1-999999> source mac-address <mac-address>
```

Only in the source criteria, you can specify a mac-address.

```
set firewall ipv6 input filter rule 100 source mac-address 00:53:00:11:22:33
set firewall ipv6 input filter rule 101 source mac-address !00:53:00:aa:12:34
```

```
set firewall ipv6 forward filter rule <1-999999> source port [1-65535 | portname |
start-end]
set firewall ipv6 input filter rule <1-999999> source port [1-65535 | portname |
start-end]
set firewall ipv6 output filter rule <1-999999> source port [1-65535 | portname |
start-end]
set firewall ipv6 name <name> rule <1-999999> source port [1-65535 | portname |
start-end]
set firewall ipv6 forward filter rule <1-999999> destination port [1-65535 | portname |
start-end]
set firewall ipv6 input filter rule <1-999999> destination port [1-65535 | portname |
start-end]
set firewall ipv6 output filter rule <1-999999> destination port [1-65535 | portname |
start-end]
set firewall ipv6 name <name> rule <1-999999> destination port [1-65535 | portname |
start-end]
```

A port can be set with a port number or a name which is here defined: /etc/services.

```
set firewall ipv6 forward filter rule 10 source port '22'
set firewall ipv6 forward filter rule 11 source port '!http'
set firewall ipv6 forward filter rule 12 source port 'https'
```

Multiple source ports can be specified as a comma-separated list. The whole list can also be „negated“ using !. For example:

```
set firewall ipv6 forward filter rule 10 source port '!22,https,3333-3338'
```

```

set firewall ipv6 forward filter rule <1-999999> source group address-group <name | !
name>
set firewall ipv6 input filter rule <1-999999> source group address-group <name | !name>
set firewall ipv6 output filter rule <1-999999> source group address-group <name | !name>
set firewall ipv6 name <name> rule <1-999999> source group address-group <name | !name>
set firewall ipv6 forward filter rule <1-999999> destination group address-group <name |
!name>
set firewall ipv6 input filter rule <1-999999> destination group address-group <name |
!name>
set firewall ipv6 output filter rule <1-999999> destination group address-group <name |
!name>
set firewall ipv6 name <name> rule <1-999999> destination group address-group <name |
!name>

```

Use a specific address-group. Prepend character ! for inverted matching criteria.

```

set firewall ipv6 forward filter rule <1-999999> source group dynamic-address-group <name
| !name>
set firewall ipv6 input filter rule <1-999999> source group dynamic-address-group <name |
!name>
set firewall ipv6 output filter rule <1-999999> source group dynamic-address-group <name
| !name>
set firewall ipv6 name <name> rule <1-999999> source group dynamic-address-group <name |
!name>
set firewall ipv6 forward filter rule <1-999999> destination group dynamic-address-group
<name | !name>
set firewall ipv6 input filter rule <1-999999> destination group dynamic-address-group
<name | !name>
set firewall ipv6 output filter rule <1-999999> destination group dynamic-address-group
<name | !name>
set firewall ipv6 name <name> rule <1-999999> destination group dynamic-address-group
<name | !name>

```

Use a specific dynamic-address-group. Prepend character ! for inverted matching criteria.

```

set firewall ipv6 forward filter rule <1-999999> source group network-group <name | !
name>
set firewall ipv6 input filter rule <1-999999> source group network-group <name | !name>
set firewall ipv6 output filter rule <1-999999> source group network-group <name | !name>
set firewall ipv6 name <name> rule <1-999999> source group network-group <name | !name>
set firewall ipv6 forward filter rule <1-999999> destination group network-group <name |
!name>
set firewall ipv6 input filter rule <1-999999> destination group network-group <name |
!name>
set firewall ipv6 output filter rule <1-999999> destination group network-group <name |
!name>

```

```
set firewall ipv6 name <name> rule <1-999999> destination group network-group <name | !name>
```

Use a specific network-group. Prepend character ! for inverted matching criteria.

```
set firewall ipv6 forward filter rule <1-999999> source group port-group <name | !name>
```

```
set firewall ipv6 input filter rule <1-999999> source group port-group <name | !name>
```

```
set firewall ipv6 output filter rule <1-999999> source group port-group <name | !name>
```

```
set firewall ipv6 name <name> rule <1-999999> source group port-group <name | !name>
```

```
set firewall ipv6 forward filter rule <1-999999> destination group port-group <name | !name>
```

```
set firewall ipv6 input filter rule <1-999999> destination group port-group <name | !name>
```

```
set firewall ipv6 output filter rule <1-999999> destination group port-group <name | !name>
```

```
set firewall ipv6 name <name> rule <1-999999> destination group port-group <name | !name>
```

Use a specific port-group. Prepend character ! for inverted matching criteria.

```
set firewall ipv6 forward filter rule <1-999999> source group domain-group <name | !name>
```

```
set firewall ipv6 input filter rule <1-999999> source group domain-group <name | !name>
```

```
set firewall ipv6 output filter rule <1-999999> source group domain-group <name | !name>
```

```
set firewall ipv6 name <name> rule <1-999999> source group domain-group <name | !name>
```

```
set firewall ipv6 forward filter rule <1-999999> destination group domain-group <name | !name>
```

```
set firewall ipv6 input filter rule <1-999999> destination group domain-group <name | !name>
```

```
set firewall ipv6 output filter rule <1-999999> destination group domain-group <name | !name>
```

```
set firewall ipv6 name <name> rule <1-999999> destination group domain-group <name | !name>
```

Use a specific domain-group. Prepend character ! for inverted matching criteria.

```
set firewall ipv6 forward filter rule <1-999999> source group mac-group <name | !name>
```

```
set firewall ipv6 input filter rule <1-999999> source group mac-group <name | !name>
```

```
set firewall ipv6 output filter rule <1-999999> source group mac-group <name | !name>
```

```
set firewall ipv6 name <name> rule <1-999999> source group mac-group <name | !name>
```

```
set firewall ipv6 forward filter rule <1-999999> destination group mac-group <name | !name>
```

```
set firewall ipv6 input filter rule <1-999999> destination group mac-group <name | !name>
```

```
set firewall ipv6 output filter rule <1-999999> destination group mac-group <name | !name>
```

```
set firewall ipv6 name <name> rule <1-999999> destination group mac-group <name | !name>
```

Use a specific mac-group. Prepend character ! for inverted matching criteria.

```

set firewall ipv6 forward filter rule <1-999999> dscp [0-63 | start-end]
set firewall ipv6 input filter rule <1-999999> dscp [0-63 | start-end]
set firewall ipv6 output filter rule <1-999999> dscp [0-63 | start-end]
set firewall ipv6 name <name> rule <1-999999> dscp [0-63 | start-end]
set firewall ipv6 forward filter rule <1-999999> dscp-exclude [0-63 | start-end]
set firewall ipv6 input filter rule <1-999999> dscp-exclude [0-63 | start-end]
set firewall ipv6 output filter rule <1-999999> dscp-exclude [0-63 | start-end]
set firewall ipv6 name <name> rule <1-999999> dscp-exclude [0-63 | start-end]

```

Match based on dscp value.

```

set firewall ipv6 forward filter rule <1-999999> fragment [match-frag | match-non-frag]
set firewall ipv6 input filter rule <1-999999> fragment [match-frag | match-non-frag]
set firewall ipv6 output filter rule <1-999999> fragment [match-frag | match-non-frag]
set firewall ipv6 name <name> rule <1-999999> fragment [match-frag | match-non-frag]

```

Match based on fragment criteria.

```

set firewall ipv6 forward filter rule <1-999999> icmpv6 [code | type] <0-255>
set firewall ipv6 input filter rule <1-999999> icmpv6 [code | type] <0-255>
set firewall ipv6 output filter rule <1-999999> icmpv6 [code | type] <0-255>
set firewall ipv6 name <name> rule <1-999999> icmpv6 [code | type] <0-255>

```

Match based on icmp|icmpv6 code and type.

```

set firewall ipv6 forward filter rule <1-999999> icmpv6 type-name <text>
set firewall ipv6 input filter rule <1-999999> icmpv6 type-name <text>
set firewall ipv6 output filter rule <1-999999> icmpv6 type-name <text>
set firewall ipv6 name <name> rule <1-999999> icmpv6 type-name <text>

```

Match based on icmpv6 type-name criteria. Use tab for information about what **type-name** criteria are supported.

```

set firewall ipv6 forward filter rule <1-999999> inbound-interface name <iface>
set firewall ipv6 input filter rule <1-999999> inbound-interface name <iface>
set firewall ipv6 name <name> rule <1-999999> inbound-interface name <iface>

```

Match based on inbound interface. Wildcard \* can be used. For example: eth2\*. Prepending character ! for inverted matching criteria is also supported. For example !eth2

```

set firewall ipv6 forward filter rule <1-999999> inbound-interface group <iface_group>
set firewall ipv6 input filter rule <1-999999> inbound-interface group <iface_group>
set firewall ipv6 name <name> rule <1-999999> inbound-interface group <iface_group>

```

Match based on inbound interface group. Prepending character ! for inverted matching criteria is also supported. For example !IFACE\_GROUP

```

set firewall ipv6 forward filter rule <1-999999> outbound-interface name <iface>
set firewall ipv6 output filter rule <1-999999> outbound-interface name <iface>

```

```
set firewall ipv6 name <name> rule <1-999999> outbound-interface name <iface>
```

Match based on outbound interface. Wildcard \* can be used. For example: eth2\*. Prepending character ! for inverted matching criteria is also supported. For example !eth2

```
set firewall ipv6 forward filter rule <1-999999> outbound-interface group <iface_group>
```

```
set firewall ipv6 output filter rule <1-999999> outbound-interface group <iface_group>
```

```
set firewall ipv6 name <name> rule <1-999999> outbound-interface group <iface_group>
```

Match based on outbound interface group. Prepending character ! for inverted matching criteria is also supported. For example !IFACE\_GROUP

```
set firewall ipv6 forward filter rule <1-999999> ipsec [match-ipsec | match-none]
```

```
set firewall ipv6 input filter rule <1-999999> ipsec [match-ipsec | match-none]
```

```
set firewall ipv6 output filter rule <1-999999> ipsec [match-ipsec | match-none]
```

```
set firewall ipv6 name <name> rule <1-999999> ipsec [match-ipsec | match-none]
```

Match based on ipsec criteria.

```
set firewall ipv6 forward filter rule <1-999999> limit burst <0-4294967295>
```

```
set firewall ipv6 input filter rule <1-999999> limit burst <0-4294967295>
```

```
set firewall ipv6 output filter rule <1-999999> limit burst <0-4294967295>
```

```
set firewall ipv6 name <name> rule <1-999999> limit burst <0-4294967295>
```

Match based on the maximum number of packets to allow in excess of rate.

```
set firewall ipv6 forward filter rule <1-999999> limit rate <text>
```

```
set firewall ipv6 input filter rule <1-999999> limit rate <text>
```

```
set firewall ipv6 output filter rule <1-999999> limit rate <text>
```

```
set firewall ipv6 name <name> rule <1-999999> limit rate <text>
```

Match based on the maximum average rate, specified as integer/unit. For example 5/minutes

```
set firewall ipv6 forward filter rule <1-999999> packet-length <text>
```

```
set firewall ipv6 input filter rule <1-999999> packet-length <text>
```

```
set firewall ipv6 output filter rule <1-999999> packet-length <text>
```

```
set firewall ipv6 name <name> rule <1-999999> packet-length <text>
```

```
set firewall ipv6 forward filter rule <1-999999> packet-length-exclude <text>
```

```
set firewall ipv6 input filter rule <1-999999> packet-length-exclude <text>
```

```
set firewall ipv6 output filter rule <1-999999> packet-length-exclude <text>
```

```
set firewall ipv6 name <name> rule <1-999999> packet-length-exclude <text>
```

Match based on packet length criteria. Multiple values from 1 to 65535 and ranges are supported.

```
set firewall ipv6 forward filter rule <1-999999> packet-type [broadcast | host |  
multicast | other]
```

```
set firewall ipv6 input filter rule <1-999999> packet-type [broadcast | host | multicast  
| other]
```

```
set firewall ipv6 output filter rule <1-999999> packet-type [broadcast | host | multicast  
| other]
```

```
set firewall ipv6 name <name> rule <1-999999> packet-type [broadcast | host | multicast |
other]
```

Match based on packet type criteria.

```
set firewall ipv6 forward filter rule <1-999999> protocol [<text> | <0-255> | all |
tcp_udp]
```

```
set firewall ipv6 input filter rule <1-999999> protocol [<text> | <0-255> | all |
tcp_udp]
```

```
set firewall ipv6 output filter rule <1-999999> protocol [<text> | <0-255> | all |
tcp_udp]
```

```
set firewall ipv6 name <name> rule <1-999999> protocol [<text> | <0-255> | all | tcp_udp]
```

Match a protocol criteria. A protocol number or a name which is here defined: /etc/protocols. Special names are all for all protocols and tcp\_udp for tcp and udp based packets. The ! negate the selected protocol.

```
set firewall ipv6 input filter rule 10 protocol tcp
```

```
set firewall ipv6 forward filter rule <1-999999> recent count <1-255>
```

```
set firewall ipv6 input filter rule <1-999999> recent count <1-255>
```

```
set firewall ipv6 output filter rule <1-999999> recent count <1-255>
```

```
set firewall ipv6 name <name> rule <1-999999> recent count <1-255>
```

```
set firewall ipv6 forward filter rule <1-999999> recent time [second | minute | hour]
```

```
set firewall ipv6 input filter rule <1-999999> recent time [second | minute | hour]
```

```
set firewall ipv6 output filter rule <1-999999> recent time [second | minute | hour]
```

```
set firewall ipv6 name <name> rule <1-999999> recent time [second | minute | hour]
```

Match bases on recently seen sources.

```
set firewall ipv6 forward filter rule <1-999999> tcp flags [not] <text>
```

```
set firewall ipv6 input filter rule <1-999999> tcp flags [not] <text>
```

```
set firewall ipv6 output filter rule <1-999999> tcp flags [not] <text>
```

```
set firewall ipv6 name <name> rule <1-999999> tcp flags [not] <text>
```

Allowed values fpr TCP flags: ack, cwr, ecn, fin, psh, rst, syn and urg. Multiple values are supported, and for inverted selection use not, as shown in the example.

```
set firewall ipv6 input filter rule 10 tcp flags 'ack'
set firewall ipv6 input filter rule 12 tcp flags 'syn'
set firewall ipv6 input filter rule 13 tcp flags not 'fin'
```

```
set firewall ipv6 forward filter rule <1-999999> state [established | invalid | new |
related]
```

```
set firewall ipv6 input filter rule <1-999999> state [established | invalid | new |
related]
```

```
set firewall ipv6 output filter rule <1-999999> state [established | invalid | new |
related]
```

```
set firewall ipv6 name <name> rule <1-999999> state [established | invalid | new |
related]
```

Match against the state of a packet.

```
set firewall ipv6 forward filter rule <1-999999> time startdate <text>
set firewall ipv6 input filter rule <1-999999> time startdate <text>
set firewall ipv6 output filter rule <1-999999> time startdate <text>
set firewall ipv6 name <name> rule <1-999999> time startdate <text>
set firewall ipv6 forward filter rule <1-999999> time starttime <text>
set firewall ipv6 input filter rule <1-999999> time starttime <text>
set firewall ipv6 output filter rule <1-999999> time starttime <text>
set firewall ipv6 name <name> rule <1-999999> time starttime <text>
set firewall ipv6 forward filter rule <1-999999> time stopdate <text>
set firewall ipv6 input filter rule <1-999999> time stopdate <text>
set firewall ipv6 output filter rule <1-999999> time stopdate <text>
set firewall ipv6 name <name> rule <1-999999> time stopdate <text>
set firewall ipv6 forward filter rule <1-999999> time stoptime <text>
set firewall ipv6 input filter rule <1-999999> time stoptime <text>
set firewall ipv6 output filter rule <1-999999> time stoptime <text>
set firewall ipv6 name <name> rule <1-999999> time stoptime <text>
set firewall ipv6 forward filter rule <1-999999> time weekdays <text>
set firewall ipv6 input filter rule <1-999999> time weekdays <text>
set firewall ipv6 output filter rule <1-999999> time weekdays <text>
set firewall ipv6 name <name> rule <1-999999> time weekdays <text>
```

Time to match the defined rule.

```
set firewall ipv6 forward filter rule <1-999999> hop-limit <eq | gt | lt> <0-255>
set firewall ipv6 input filter rule <1-999999> hop-limit <eq | gt | lt> <0-255>
set firewall ipv6 output filter rule <1-999999> hop-limit <eq | gt | lt> <0-255>
set firewall ipv6 name <name> rule <1-999999> hop-limit <eq | gt | lt> <0-255>
```

Match hop-limit parameter, where ,eq‘ stands for ,equal‘; ,gt‘ stands for ,greater than‘, and ,lt‘ stands for ,less than‘.

```
set firewall ipv6 forward filter rule <1-999999> recent count <1-255>
set firewall ipv6 input filter rule <1-999999> recent count <1-255>
set firewall ipv6 output filter rule <1-999999> recent count <1-255>
set firewall ipv6 name <name> rule <1-999999> recent count <1-255>
set firewall ipv6 forward filter rule <1-999999> recent time <second | minute | hour>
set firewall ipv6 input filter rule <1-999999> recent time <second | minute | hour>
set firewall ipv6 output filter rule <1-999999> recent time <second | minute | hour>
set firewall ipv6 name <name> rule <1-999999> recent time <second | minute | hour>
```

Match when ,count‘ amount of connections are seen within ,time‘. These matching criteria can be used to block brute-force attempts.

## Synproxy

Synproxy connections

```
set firewall ipv6 [input | forward] filter rule <1-999999> action synproxy
set firewall ipv6 [input | forward] filter rule <1-999999> protocol tcp
set firewall ipv6 [input | forward] filter rule <1-999999> synproxy tcp mss <501-65535>
```

Set TCP-MSS (maximum segment size) for the connection

```
set firewall ipv6 [input | forward] filter rule <1-999999> synproxy tcp window-scale <1-14>
```

Set the window scale factor for TCP window scaling

## Example synproxy

Requirements to enable synproxy:

- Traffic must be symmetric
- Synproxy relies on syncookies and TCP timestamps, ensure these are enabled
- Disable conntrack loose track option

```
set system sysctl parameter net.ipv4.tcp_timestamps value '1'

set system conntrack tcp loose disable
set system conntrack ignore ipv6 rule 10 destination port '8080'
set system conntrack ignore ipv6 rule 10 protocol 'tcp'
set system conntrack ignore ipv6 rule 10 tcp flags syn

set firewall global-options syn-cookies 'enable'
set firewall ipv6 input filter rule 10 action 'synproxy'
set firewall ipv6 input filter rule 10 destination port '8080'
set firewall ipv6 input filter rule 10 inbound-interface name 'eth1'
set firewall ipv6 input filter rule 10 protocol 'tcp'
set firewall ipv6 input filter rule 10 synproxy tcp mss '1460'
set firewall ipv6 input filter rule 10 synproxy tcp window-scale '7'
set firewall ipv6 input filter rule 1000 action 'drop'
set firewall ipv6 input filter rule 1000 state invalid
```

## Operation-mode Firewall

### Rule-set overview

#### show firewall

This will show you a basic firewall overview

```
vyos@vyos:~$ show firewall
Rulesets Information

-----
IPv4 Firewall "forward filter"

Rule      Action    Protocol    Packets    Bytes    Conditions
-----
5          jump      all         0          0        iifname "eth1"  jump NAME_VyOS_
MANAGEMENT
10         jump      all         0          0        oifname "eth1"  jump NAME_WAN_IN
15         jump      all         0          0        iifname "eth3"  jump NAME_WAN_IN
default    accept    all

-----
IPv4 Firewall "name VyOS_MANAGEMENT"

Rule      Action    Protocol    Packets    Bytes    Conditions
-----
5          accept    all         0          0        ct state established accept
10         drop      all         0          0        ct state invalid
20         accept    all         0          0        ip saddr @A_GOOD_GUYS accept
30         accept    all         0          0        ip saddr @N_ENTIRE_RANGE accept
40         accept    all         0          0        ip saddr @A_VyOS_SERVERS accept

Rule      Action    Protocol
-----
5          jump      all
default    accept    all
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
-----
IPv6 Firewall "ipv6_name IPV6-VyOS_MANAGEMENT"
```

| Rule    | Action | Protocol  |
|---------|--------|-----------|
| 5       | accept | all       |
| 10      | drop   | all       |
| 20      | accept | all       |
| 30      | accept | all       |
| 40      | accept | all       |
| 50      | accept | ipv6-icmp |
| default | drop   | all       |

**show firewall summary**

This will show you a summary of rule-sets and groups

```
vyos@vyos:~$ show firewall summary
Ruleset Summary
```

IPv6 Ruleset:

| Ruleset Hook | Ruleset Priority     | Description     |
|--------------|----------------------|-----------------|
| forward      | filter               |                 |
| input        | filter               |                 |
| ipv6_name    | IPV6-VyOS_MANAGEMENT |                 |
| ipv6_name    | IPV6-WAN_IN          | PUBLIC_INTERNET |

IPv4 Ruleset:

| Ruleset Hook | Ruleset Priority | Description     |
|--------------|------------------|-----------------|
| forward      | filter           |                 |
| input        | filter           |                 |
| name         | VyOS_MANAGEMENT  |                 |
| name         | WAN_IN           | PUBLIC_INTERNET |

Firewall Groups

| Name    | Type          | References         | Members       |
|---------|---------------|--------------------|---------------|
| → --    |               |                    |               |
| PBX     | address_group | WAN_IN-100         | 198.51.100.77 |

**show firewall ipv6 [forward | input | output] filter**

**show firewall ipv6 ipv6-name <name>**

This command will give an overview of a single rule-set.

```
vyos@vyos:~$ show firewall ipv6 input filter
Ruleset Information

-----
ipv6 Firewall "input filter"

Rule      Action    Protocol    Packets    Bytes    Conditions
-----
10        jump      all         13         1456     iifname "eth1" jump NAME6_INP-
10        →ETH1
20        accept    ipv6-icmp   10         1112     meta l4proto ipv6-icmp iifname
20        →"eth0" prefix "[ipv6-INP-filter-20-A]" accept
default   accept    all         14         1584
```

**show firewall ipv6 [forward | input | output] filter rule <1-999999>**

**show firewall ipv6 name <name> rule <1-999999>**

**show firewall ipv6 ipv6-name <name> rule <1-999999>**

This command will give an overview of a rule in a single rule-set

**show firewall group <name>**

Overview of defined groups. You see the type, the members, and where the group is used.

```
vyos@vyos:~$ show firewall group LAN
Firewall Groups

Name      Type                References          Members
-----
LAN       ipv6_network_group  IPV6-VyOS_MANAGEMENT-30  2001:db8::0/64
                        IPV6-WAN_IN-30
```

### show firewall statistics

This will show of all firewall; show all ipv6 firewall logs; show all logs for particular hook; show all logs for particular hook and priority; show all logs for particular custom chain; show logs for specific Rule-Set.

### Show Firewall log

```
show log firewall
```

```
show log firewall ipv6
```

```
show log firewall ipv6 [forward | input | output | name]
```

```
show log firewall ipv6 [forward | input | output] filter
```

```
show log firewall ipv6 name <name>
```

```
show log firewall ipv6 [forward | input | output] filter rule <rule>
```

```
show log firewall ipv6 name <name> rule <rule>
```

Show the logs of all firewall; show all ipv6 firewall logs; show all logs for particular hook; show all logs for particular hook and priority; show all logs for particular custom chain; show logs for specific Rule-Set.

### Example Partial Config

```
firewall {
  ipv6 {
    input {
      filter {
        rule 10 {
          action jump
          inbound-interface {
            name eth1
          }
          jump-target INP-ETH1
        }
        rule 20 {
          action accept
          inbound-interface {
            name eth0
          }
          log
          protocol ipv6-icmp
        }
      }
    }
    name INP-ETH1 {
      default-action drop
      default-log
      rule 10 {
        action accept

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
}  
}  
}  
} protocol tcp_udp
```

## Update geoip database

## update geoip

Command used to update GeoIP database and firewall sets.

### 8.2.6 Flowtables Firewall Configuration

**Bemerkung:** Documentation under development

## Overview

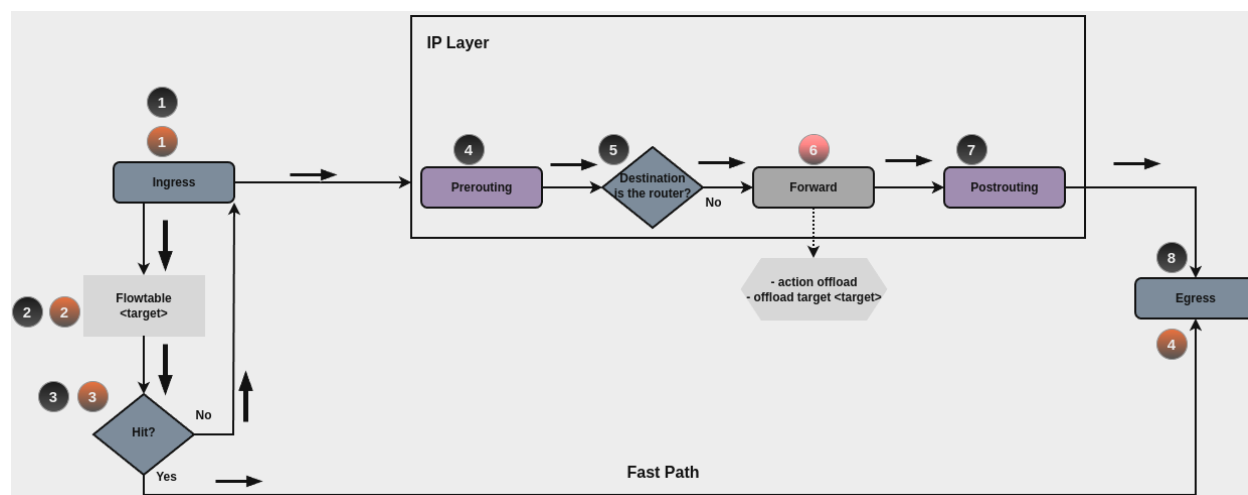

In this section there's useful information of all firewall configuration that can be done regarding flowtables.

```
set firewall flowtables ...
```

From main structure defined in *Firewall Overview* in this section you can find detailed information only for the next part of the general structure:

```
- set firewall
    * flowtable
        - custom_flow_table
            + ...
```

Flowtables allows you to define a fastpath through the flowtable datapath. The flowtable supports for the layer 3 IPv4 and IPv6 and the layer 4 TCP and UDP protocols.

Once the first packet of the flow successfully goes through the IP forwarding path (black circles path), from the second packet on, you might decide to offload the flow to the flowtable through your ruleset. The flowtable infrastructure provides a rule action that allows you to specify when to add a flow to the flowtable (On forward filtering, red circle number 6)

A packet that finds a matching entry in the flowtable (flowtable hit) is transmitted to the output netdevice, hence, packets bypass the classic IP forwarding path and uses the **Fast Path** (orange circles path). The visible effect is that you do not see these packets from any of the Netfilter hooks coming after ingress. In case that there is no matching entry in the flowtable (flowtable miss), the packet follows the classic IP forwarding path.

---

**Bemerkung: Flowtable Reference:** [https://docs.kernel.org/networking/nf\\_flowtable.html](https://docs.kernel.org/networking/nf_flowtable.html)

---

## Flowtable Configuration

In order to use flowtables, the minimal configuration needed includes:

- Create flowtable: create flowtable, which includes the interfaces that are going to be used by the flowtable.
- Create firewall rule: create a firewall rule, setting action to offload and using desired flowtable for offload-target.

Creating a flow table:

```
set firewall flowtable <flow_table_name> interface <iface>
```

Define interfaces to be used in the flowtable.

```
set firewall flowtable <flow_table_name> description <text>
```

Provide a description to the flow table.

```
set firewall flowtable <flow_table_name> offload <hardware | software>
```

Define type of offload to be used by the flowtable: hardware or software. By default, software offload is used.

---

**Bemerkung: Hardware offload:** should be supported by the NICs used.

---

Creating rules for using flow tables:

```
set firewall [ipv4 | ipv6] forward filter rule <1-999999> action offload
```

Create firewall rule in forward chain, and set action to offload.

```
set firewall [ipv4 | ipv6] forward filter rule <1-999999> offload-target <flowtable>
```

Create firewall rule in forward chain, and define which flowtable should be used. Only applicable if action is offload.

## Configuration Example

Things to be considered in this setup:

- Two interfaces are going to be used in the flowtables: eth0 and eth1
- Minimum firewall ruleset is provided, which includes some filtering rules, and appropriate rules for using flowtable offload capabilities.

As described, first packet will be evaluated by all the firewall path, so desired connection should be explicitly accepted. Same thing should be taken into account for traffic in reverse order. In most cases state policies are used in order to accept connection in reverse patch.

We will only accept traffic coming from interface eth0, protocol tcp and destination port 1122. All other traffic trespassing the router should be blocked.

## Commands

```
set firewall flowtable FT01 interface 'eth0'
set firewall flowtable FT01 interface 'eth1'
set firewall ipv4 forward filter default-action 'drop'
set firewall ipv4 forward filter rule 10 action 'offload'
set firewall ipv4 forward filter rule 10 offload-target 'FT01'
set firewall ipv4 forward filter rule 10 state 'established'
set firewall ipv4 forward filter rule 10 state 'related'
set firewall ipv4 forward filter rule 20 action 'accept'
set firewall ipv4 forward filter rule 20 state 'established'
set firewall ipv4 forward filter rule 20 state 'related'
set firewall ipv4 forward filter rule 110 action 'accept'
set firewall ipv4 forward filter rule 110 destination address '192.0.2.100'
set firewall ipv4 forward filter rule 110 destination port '1122'
set firewall ipv4 forward filter rule 110 inbound-interface name 'eth0'
set firewall ipv4 forward filter rule 110 protocol 'tcp'
```

## Explanation

Analysis on what happens for desired connection:

1. First packet is received on eth0, with destination address 192.0.2.100, protocol tcp and destination port 1122. Assume such destination address is reachable through interface eth1.
2. Since this is the first packet, connection status of this connection, so far is **new**. So neither rule 10 nor 20 are valid.
3. Rule 110 is hit, so connection is accepted.
4. Once answer from server 192.0.2.100 is seen in opposite direction, connection state will be triggered to **established**, so this reply is accepted in rule 20.
5. Second packet for this connection is received by the router. Since connection state is **established**, then rule 10 is hit, and a new entry in the flowtable FT01 is added for this connection.
6. All subsequent packets will skip traditional path, and will be offloaded and will use the **Fast Path**.

## Checks

It's time to check conntrack table, to see if any connection was accepted, and if was properly offloaded

```
vyos@FlowTables:~$ show firewall ipv4 forward filter
Ruleset Information

-----
ipv4 Firewall "forward filter"
-----
Rule      Action    Protocol  Packets  Bytes  Conditions
-----
10        offload   all       8        468    ct state { established, related }
→flow add @VYOS_FLOWTABLE_FT01
20        accept    all       8        468    ct state { established, related }
→accept
110       accept    tcp       2        120    ip daddr 192.0.2.100 tcp dport 1122
→iifname "eth0" accept
default   drop      all       7        420

vyos@FlowTables:~$ sudo conntrack -L | grep tcp
conntrack v1.4.6 (conntrack-tools): 5 flow entries have been shown.
tcp      6 src=198.51.100.100 dst=192.0.2.100 sport=41676 dport=1122 src=192.0.2.100
→dst=198.51.100.100 sport=1122 dport=41676 [OFFLOAD] mark=0 use=2
vyos@FlowTables:~$
```

**Bemerkung:** For more information of Netfilter hooks and Linux networking packet flows can be found in [Netfilter-Hooks](#)

## 8.2.7 Zone-based firewall

### Zone Based Firewall

#### Overview

**Bemerkung:** Starting from VyOS 1.4-rolling-202308040557, a new firewall structure can be found on all VyOS installations. Zone based firewall was removed in that version, but re introduced in VyOS 1.4 and 1.5. All versions built after 2023-10-22 has this feature. Documentation for most of the new firewall CLI can be found in the [firewall](#) chapter. The legacy firewall is still available for versions before 1.4-rolling-202308040557 and can be found in the [legacy firewall configuration](#) chapter.

In this section there's useful information of all firewall configuration that is needed for zone-based firewall. Configuration commands covered in this section:

**set firewall zone ...**

From main structure defined in [Firewall Overview](#) in this section you can find detailed information only for the next part of the general structure:

```
- set firewall
  * zone
    - custom_zone_name
    + ...
```

In zone-based policy, interfaces are assigned to zones, and inspection policy is applied to traffic moving between the zones and acted on according to firewall rules. A zone is a group of interfaces that have similar functions or features. It establishes the security borders of a network. A zone defines a boundary where traffic is subjected to policy restrictions as it crosses to another region of a network.

Key Points:

- A zone must be configured before an interface is assigned to it and an interface can be assigned to only a single zone.
- All traffic to and from an interface within a zone is permitted.
- All traffic between zones is affected by existing policies
- Traffic cannot flow between zone member interface and any interface that is not a zone member.
- You need 2 separate firewalls to define traffic: one for each direction.

---

**Bemerkung:** In T2199 the syntax of the zone configuration was changed. The zone configuration moved from `zone-policy zone <name>` to `firewall zone <name>`.

---

## Configuration

As an alternative to applying policy to an interface directly, a zone-based firewall can be created to simplify configuration when multiple interfaces belong to the same security zone. Instead of applying rule-sets to interfaces, they are applied to source zone-destination zone pairs.

A basic introduction to zone-based firewalls can be found [here](#), and an example at [Zone-Policy example](#).

## Define a Zone

To define a zone setup either one with interfaces or a local zone.

**set firewall zone <name> interface <interface>**

Set interfaces to a zone. A zone can have multiple interfaces. But an interface can only be a member in one zone.

**set firewall zone <name> local-zone**

Define the zone as a local zone. A local zone has no interfaces and will be applied to the router itself.

**set firewall zone <name> default-action [drop | reject]**

Change the default-action with this setting.

**set firewall zone <name> description**

Set a meaningful description.

## Applying a Rule-Set to a Zone

Before you are able to apply a rule-set to a zone you have to create the zones first.

It helps to think of the syntax as: (see below). The ,rule-set' should be written from the perspective of: *Source Zone-to->\*Destination Zone\**

```
set firewall zone <Destination Zone> from <Source Zone> firewall name <rule-set>
```

```
set firewall zone <name> from <name> firewall name <rule-set>
```

```
set firewall zone <name> from <name> firewall ipv6-name <rule-set>
```

You apply a rule-set always to a zone from an other zone, it is recommended to create one rule-set for each zone pair.

```
set firewall zone DMZ from LAN firewall name LANv4-to-DMZv4
set firewall zone LAN from DMZ firewall name DMZv4-to-LANv4
```

## Operation-mode

### show firewall zone-policy

This will show you a basic summary of zones configuration.

```
vyos@vyos:~$ show firewall zone-policy
```

| Zone  | Interfaces   | From Zone    | Firewall IPv4                | Firewall IPv6   |
|-------|--------------|--------------|------------------------------|-----------------|
| LAN   | eth1<br>eth2 | WAN          | WAN_to_LAN                   |                 |
| LOCAL | LOCAL        | LAN<br>WAN   | LAN_to_LOCAL<br>WAN_to_LOCAL | WAN_to_LOCAL_v6 |
| WAN   | eth3<br>eth0 | LAN<br>LOCAL | LAN_to_WAN<br>LOCAL_to_WAN   |                 |

```
vyos@vyos:~$
```

### show firewall zone-policy zone <zone>

This will show you a basic summary of a particular zone.

```
vyos@vyos:~$ show firewall zone-policy zone WAN
```

| Zone | Interfaces   | From Zone    | Firewall IPv4              | Firewall IPv6 |
|------|--------------|--------------|----------------------------|---------------|
| WAN  | eth3<br>eth0 | LAN<br>LOCAL | LAN_to_WAN<br>LOCAL_to_WAN |               |

```
vyos@vyos:~$ show firewall zone-policy zone LOCAL
```

| Zone  | Interfaces | From Zone  | Firewall IPv4                | Firewall IPv6   |
|-------|------------|------------|------------------------------|-----------------|
| LOCAL | LOCAL      | LAN<br>WAN | LAN_to_LOCAL<br>WAN_to_LOCAL | WAN_to_LOCAL_v6 |

```
vyos@vyos:~$
```

With zone-based firewalls a new concept was implemented, in addition to the standard in and out traffic flows, a local flow was added. This local was for traffic originating and destined to the router itself. Which means additional rules were required to secure the firewall itself from the network, in addition to the existing inbound and outbound rules from the traditional concept above.

To configure VyOS with the *zone-based firewall configuration*

As the example image below shows, the device now needs rules to allow/block traffic to or from the services running on the device that have open connections on that interface.

## 8.3 High availability

VRRP (Virtual Router Redundancy Protocol) provides active/backup redundancy for routers. Every VRRP router has a physical IP/IPv6 address, and a virtual address. On startup, routers elect the master, and the router with the highest priority becomes the master and assigns the virtual address to its interface. All routers with lower priorities become backup routers. The master then starts sending keepalive packets to notify other routers that it's available. If the master fails and stops sending keepalive packets, the router with the next highest priority becomes the new master and takes over the virtual address.

VRRP keepalive packets use multicast, and VRRP setups are limited to a single datalink layer segment. You can setup multiple VRRP groups (also called virtual routers). Virtual routers are identified by a VRID (Virtual Router Identifier). If you setup multiple groups on the same interface, their VRIDs must be unique if they use the same address family, but it's possible (even if not recommended for readability reasons) to use duplicate VRIDs on different interfaces.

### 8.3.1 Basic setup

VRRP groups are created with the `set high-availability vrrp group $GROUP_NAME` commands. The required parameters are interface, vrid, and address.

minimal config

```
set high-availability vrrp group Foo vrid 10
set high-availability vrrp group Foo interface eth0
set high-availability vrrp group Foo address 192.0.2.1/24
```

You can verify your VRRP group status with the operational mode `run show vrrp` command:

```
vyos@vyos# run show vrrp
Name      Interface  VRID  State  Last Transition
-----
Foo       eth1       10    MASTER 2s
```

### 8.3.2 IPv6 support

The address parameter can be either an IPv4 or IPv6 address, but you can not mix IPv4 and IPv6 in the same group, and will need to create groups with different VRIDs specially for IPv4 and IPv6. If you want to use IPv4 + IPv6 address you can use option `excluded-address`

### 8.3.3 Address

The address can be configured either on the VRRP interface or on not VRRP interface.

```
set high-availability vrrp group Foo address 192.0.2.1/24
set high-availability vrrp group Foo address 203.0.113.22/24 interface eth2
set high-availability vrrp group Foo address 198.51.100.33/24 interface eth3
```

### 8.3.4 Disabling a VRRP group

You can disable a VRRP group with `disable` option:

```
set high-availability vrrp group Foo disable
```

A disabled group will be removed from the VRRP process and your router will not participate in VRRP for that VRID. It will disappear from operational mode commands output, rather than enter the backup state.

### 8.3.5 Exclude address

Exclude IP addresses from VRRP packets. This option `excluded-address` is used when you want to set IPv4 + IPv6 addresses on the same virtual interface or when used more than 20 IP addresses.

```
set high-availability vrrp group Foo excluded-address '203.0.113.254/24'
set high-availability vrrp group Foo excluded-address '2001:db8:aa::1/64'
set high-availability vrrp group Foo excluded-address '2001:db8:22::1/64'
```

### 8.3.6 Setting VRRP group priority

VRRP priority can be set with `priority` option:

```
set high-availability vrrp group Foo priority 200
```

The priority must be an integer number from 1 to 255. Higher priority value increases router's precedence in the master elections.

### 8.3.7 Sync groups

A sync group allows VRRP groups to transition together.

```
edit high-availability vrrp
set sync-group MAIN member VLAN9
set sync-group MAIN member VLAN20
```

In the following example, when VLAN9 transitions, VLAN20 will also transition:

```
vrrp {
  group VLAN9 {
    interface eth0.9
    address 10.9.1.1/24
    priority 200
    vrid 9
  }
  group VLAN20 {
    interface eth0.20
    priority 200
    address 10.20.20.1/24
    vrid 20
  }
  sync-group MAIN {
    member VLAN20
    member VLAN9
  }
}
```

**Warnung:** All items in a sync group should be similarly configured. If one VRRP group is set to a different preemption delay or priority, it would result in an endless transition loop.

### 8.3.8 Preemption

VRRP can use two modes: preemptive and non-preemptive. In the preemptive mode, if a router with a higher priority fails and then comes back, routers with lower priority will give up their master status. In non-preemptive mode, the newly elected master will keep the master status and the virtual address indefinitely.

By default VRRP uses preemption. You can disable it with the „no-preempt“ option:

```
set high-availability vrrp group Foo no-preempt
```

You can also configure the time interval for preemption with the „preempt-delay“ option. For example, to set the higher priority router to take over in 180 seconds, use:

```
set high-availability vrrp group Foo preempt-delay 180
```

### 8.3.9 Track

Track option to track non VRRP interface states. VRRP changes status to FAULT if one of the track interfaces in state down.

```
set high-availability vrrp group Foo track interface eth0
set high-availability vrrp group Foo track interface eth1
```

Ignore VRRP main interface faults

```
set high-availability vrrp group Foo track exclude-vrrp-interface
```

### 8.3.10 Unicast VRRP

By default VRRP uses multicast packets. If your network does not support multicast for whatever reason, you can make VRRP use unicast communication instead.

```
set high-availability vrrp group Foo peer-address 192.0.2.10
set high-availability vrrp group Foo hello-source-address 192.0.2.15
```

### 8.3.11 rfc3768-compatibility

RFC 3768 defines a virtual MAC address to each VRRP virtual router. This virtual router MAC address will be used as the source in all periodic VRRP messages sent by the active node. When the rfc3768-compatibility option is set, a new VRRP interface is created, to which the MAC address and the virtual IP address is automatically assigned.

```
set high-availability vrrp group Foo rfc3768-compatibility
```

Verification

```
$show interfaces ethernet eth0v10
eth0v10@eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue
state UP group default qlen 1000
link/ether 00:00:5e:00:01:0a brd ff:ff:ff:ff:ff:ff
inet 172.25.0.247/16 scope global eth0v10
valid_lft forever preferred_lft forever
```

### 8.3.12 Global options

On most scenarios, there's no need to change specific parameters, and using default configuration is enough. But there are cases where extra configuration is needed.

**set high-availability vrrp global-parameters startup\_delay <1-600>**

This option specifies a delay in seconds before vrrp instances start up after keepalived starts.

### 8.3.13 Gratuitous ARP

These configuration is not mandatory and in most cases there's no need to configure it. But if necessary, Gratuitous ARP can be configured in `global-parameters` and/or in `group` section.

```
set high-availability vrrp global-parameters garp interval <0.000-1000>
```

```
set high-availability vrrp group <name> garp interval <0.000-1000>
```

Set delay between gratuitous ARP messages sent on an interface.

0 if not defined.

```
set high-availability vrrp global-parameters garp master-delay <1-255>
```

```
set high-availability vrrp group <name> garp master-delay <1-255>
```

Set delay for second set of gratuitous ARPs after transition to MASTER.

5 if not defined.

```
set high-availability vrrp global-parameters garp master-refresh <1-600>
```

```
set high-availability vrrp group <name> garp master-refresh <1-600>
```

Set minimum time interval for refreshing gratuitous ARPs while MASTER.

0 if not defined, which means no refreshing.

```
set high-availability vrrp global-parameters garp master-refresh-repeat <1-600>
```

```
set high-availability vrrp group <name> garp master-refresh-repeat <1-600>
```

Set number of gratuitous ARP messages to send at a time while MASTER.

1 if not defined.

```
set high-availability vrrp global-parameters garp master-repeat <1-600>
```

```
set high-availability vrrp group <name> garp master-repeat <1-600>
```

Set number of gratuitous ARP messages to send at a time after transition to MASTER.

5 if not defined.

### 8.3.14 Version

```
set high-availability vrrp global-parameters version 2|3
```

Set the default VRRP version to use. This defaults to 2, but IPv6 instances will always use version 3.

### 8.3.15 Scripting

VRRP functionality can be extended with scripts. VyOS supports two kinds of scripts: health check scripts and transition scripts. Health check scripts execute custom checks in addition to the master router reachability. Transition scripts are executed when VRRP state changes from master to backup or fault and vice versa and can be used to enable or disable certain services, for example.

## Health check scripts

This setup will make the VRRP process execute the `/config/scripts/vrrp-check.sh` script every 60 seconds, and transition the group to the fault state if it fails (i.e. exits with non-zero status) three times:

```
set high-availability vrrp group Foo health-check script /config/scripts/vrrp-check.sh
set high-availability vrrp group Foo health-check interval 60
set high-availability vrrp group Foo health-check failure-count 3
```

When the vrrp group is a member of the sync group will use only the sync group health check script. This example shows how to configure it for the sync group:

```
set high-availability vrrp sync-group Bar health-check script /config/scripts/vrrp-check.
↪sh
set high-availability vrrp sync-group Bar health-check interval 60
set high-availability vrrp sync-group Bar health-check failure-count 3
```

## Transition scripts

Transition scripts can help you implement various fixups, such as starting and stopping services, or even modifying the VyOS config on VRRP transition. This setup will make the VRRP process execute the `/config/scripts/vrrp-fail.sh` with argument `Foo` when VRRP fails, and the `/config/scripts/vrrp-master.sh` when the router becomes the master:

```
set high-availability vrrp group Foo transition-script backup "/config/scripts/vrrp-fail.
↪sh Foo"
set high-availability vrrp group Foo transition-script fault "/config/scripts/vrrp-fail.
↪sh Foo"
set high-availability vrrp group Foo transition-script master "/config/scripts/vrrp-
↪master.sh Foo"
```

To know more about scripting, check the [Command Scripting](#) section.

### 8.3.16 Virtual-server

Virtual Server allows to Load-balance traffic destination virtual-address:port between several real servers.

## Algorithm

Load-balancing schedule algorithm:

- round-robin
- weighted-round-robin
- least-connection
- weighted-least-connection
- source-hashing
- destination-hashing
- locality-based-least-connection

```
set high-availability virtual-server 203.0.113.1 algorithm 'least-connection'
```

### Forward method

- NAT
- direct
- tunnel

```
set high-availability virtual-server 203.0.113.1 forward-method 'nat'
```

### Health-check

Custom health-check script allows checking real-server availability

```
set high-availability virtual-server 203.0.113.1 real-server 192.0.2.11 health-check_
↪script <path-to-script>
```

### Fwmark

Firewall mark. It possible to loadbalancing traffic based on fwmark value

```
set high-availability virtual-server 203.0.113.1 fwmark '111'
```

### Real server

Real server IP address and port

```
set high-availability virtual-server 203.0.113.1 real-server 192.0.2.11 port '80'
```

### Example

Virtual-server can be configured with VRRP virtual address or without VRRP.

In the next example all traffic destined to 203.0.113.1 and port 8280 protocol TCP is balanced between 2 real servers 192.0.2.11 and 192.0.2.12 to port 80

Real server is auto-excluded if port check with this server fail.

```
set interfaces ethernet eth0 address '203.0.113.11/24'
set interfaces ethernet eth1 address '192.0.2.1/24'
set high-availability vrrp group F00 interface 'eth0'
set high-availability vrrp group F00 no-preempt
set high-availability vrrp group F00 priority '150'
set high-availability vrrp group F00 address '203.0.113.1/24'
set high-availability vrrp group F00 vrid '10'

set high-availability virtual-server 203.0.113.1 algorithm 'source-hashing'
set high-availability virtual-server 203.0.113.1 delay-loop '10'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set high-availability virtual-server 203.0.113.1 forward-method 'nat'
set high-availability virtual-server 203.0.113.1 persistence-timeout '180'
set high-availability virtual-server 203.0.113.1 port '8280'
set high-availability virtual-server 203.0.113.1 protocol 'tcp'
set high-availability virtual-server 203.0.113.1 real-server 192.0.2.11 port '80'
set high-availability virtual-server 203.0.113.1 real-server 192.0.2.12 port '80'

```

A firewall mark `fwmark` allows using multiple ports for high-availability virtual-server. It uses `fwmark` value.

In this example all traffic destined to ports „80, 2222, 8888“ protocol TCP marks to `fwmark „111“` and balanced between 2 real servers. Port „0“ is required if multiple ports are used.

```

set interfaces ethernet eth0 address 'dhcp'
set interfaces ethernet eth0 description 'WAN'
set interfaces ethernet eth1 address '192.0.2.1/24'
set interfaces ethernet eth1 description 'LAN'

set policy route PR interface 'eth0'
set policy route PR rule 10 destination port '80,2222,8888'
set policy route PR rule 10 protocol 'tcp'
set policy route PR rule 10 set mark '111'

set high-availability virtual-server vyos fwmark '111'
set high-availability virtual-server vyos protocol 'tcp'
set high-availability virtual-server vyos real-server 192.0.2.11 health-check script '/
↪config/scripts/check-real-server-first.sh'
set high-availability virtual-server vyos real-server 192.0.2.11 port '0'
set high-availability virtual-server vyos real-server 192.0.2.12 health-check script '/
↪config/scripts/check-real-server-second.sh'
set high-availability virtual-server vyos real-server 192.0.2.12 port '0'

set nat source rule 100 outbound-interface name 'eth0'
set nat source rule 100 source address '192.0.2.0/24'
set nat source rule 100 translation address 'masquerade'

```

Op-mode check virtual-server status

```

vyos@r14:~$ run show virtual-server
IP Virtual Server version 1.2.1 (size=4096)
Prot LocalAddress:Port Scheduler Flags
  -> RemoteAddress:Port      Forward Weight ActiveConn InActConn
FWM  111 lc persistent 300
  -> 192.0.2.11:0             Masq    1      0        0
  -> 192.0.2.12:0             Masq    1      1        0

```

## 8.4 Interfaces

### 8.4.1 Bond / Link Aggregation

The bonding interface provides a method for aggregating multiple network interfaces into a single logical „bonded“ interface, or LAG, or ether-channel, or port-channel. The behavior of the bonded interfaces depends upon the mode; generally speaking, modes provide either hot standby or load balancing services. Additionally, link integrity monitoring may be performed.

#### Configuration

##### Common interface configuration

**set interfaces bonding <interface> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
  - /config/scripts/dhcp-client/post-hooks.d/
- 

Example:

```
set interfaces bonding bond0 address 192.0.2.1/24
set interfaces bonding bond0 address 2001:db8::1/64
set interfaces bonding bond0 address dhcp
set interfaces bonding bond0 address dhcpv6
```

**set interfaces bonding <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces bonding bond0 description 'This is an awesome interface running on ↵
↳ VyOS'
```

**set interfaces bonding <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces bonding bond0 disable
```

**set interfaces bonding <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces bonding bond0 disable-flow-control
```

#### **set interfaces bonding <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces bonding bond0 disable-link-detect
```

#### **set interfaces bonding <interface> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC (Media Access Control) address on given <interface>.

Example:

```
set interfaces bonding bond0 mac '00:01:02:03:04:05'
```

#### **set interfaces bonding <interface> mtu <mtu>**

Configure MTU (Maximum Transmission Unit) on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces bonding bond0 mtu 1600
```

#### **set interfaces bonding <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

#### **set interfaces bonding <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces bonding bond0 ip arp-cache-timeout 180
```

#### **set interfaces bonding <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces bonding bond0 ip disable-arp-filter
```

#### **set interfaces bonding <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces bonding bond0 ip disable-forwarding
```

#### **set interfaces bonding <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces bonding bond0 ip enable-directed-broadcast
```

#### **set interfaces bonding <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces bonding bond0 ip enable-arp-accept
```

#### **set interfaces bonding <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces bonding bond0 ip enable-arp-announce
```

#### **set interfaces bonding <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces bonding bond0 ip enable-arp-ignore
```

#### **set interfaces bonding <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces bonding bond0 ip enable-proxy-arp
```

#### **set interfaces bonding <interface> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

#### **set interfaces bonding <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.

- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

#### **set interfaces bonding <interface> ipv6 address autoconf**

SLAAC (Stateless Address Autoconfiguration) [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 (Internet Control Message Protocol version 6) router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces bonding bond0 ipv6 address autoconf
```

#### **set interfaces bonding <interface> ipv6 address eui64 <prefix>**

EUI-64 (64-Bit Extended Unique Identifier) as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces bonding bond0 ipv6 address eui64 2001:db8:beef::/64
```

#### **set interfaces bonding <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces bonding bond0 ipv6 address no-default-link-local
```

#### **set interfaces bonding <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces bonding bond0 ipv6 disable-forwarding
```

#### **set interfaces bonding <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces bonding <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces bonding bond0 ipv6 accept-dad 2
```

**set interfaces bonding <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces bonding bond0 ipv6 dup-addr-detect-transmits 5
```

**set interfaces bonding <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces bonding bond0 vrf red
```

## DHCP(v6)

**set interfaces bonding <interface> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier‘ option. If the client supplies a ,client identifier‘, the client MUST use the same ,client identifier‘ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces bonding bond0 dhcp-options client-id 'foo-bar'
```

**set interfaces bonding <interface> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces bonding bond0 dhcp-options host-name 'VyOS'
```

**set interfaces bonding <interface> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces bonding bond0 dhcp-options vendor-class-id 'VyOS'
```

#### **set interfaces bonding <interface> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces bonding bond0 dhcp-options no-default-route
```

#### **set interfaces bonding <interface> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces bonding bond0 dhcp-options default-route-distance 220
```

#### **set interfaces bonding <interface> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces bonding bond0 dhcp-options reject 192.168.100.0/24
```

#### **set interfaces bonding <interface> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces bonding bond0 dhcp-options user-class VyOS
```

#### **set interfaces bonding <interface> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces bonding bond0 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

#### **set interfaces bonding <interface> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces bonding bond0 dhcpv6-options no-release
```

#### **set interfaces bonding <interface> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces bonding bond0 dhcpv6-options parameters-only
```

**set interfaces bonding <interface> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces bonding bond0 dhcpv6-options rapid-commit
```

**set interfaces bonding <interface> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces bonding bond0 dhcpv6-options temporary
```

### DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

**set interfaces bonding <interface> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces bonding bond0 dhcpv6-options pd 0 length 56
```

**set interfaces bonding <interface> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces bonding bond0 dhcpv6-options pd 0 interface eth8 address 65534
```

**set interfaces bonding <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:fff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:fff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces bonding bond0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## Member Interfaces

```
set interfaces bonding <interface> member interface <member>
```

Enslave <member> interface to bond <interface>.

## Bond options

```
set interfaces bonding <interface> mode <802.3ad | active-backup | broadcast |  
round-robin | transmit-load-balance | adaptive-load-balance | xor-hash>
```

Specifies one of the bonding policies. The default is 802.3ad. Possible values are:

- **802.3ad** - IEEE 802.3ad Dynamic link aggregation. Creates aggregation groups that share the same speed and duplex settings. Utilizes all slaves in the active aggregator according to the 802.3ad specification.

Slave selection for outgoing traffic is done according to the transmit hash policy, which may be changed from the default simple XOR policy via the `hash-policy` option, documented below.

---

**Bemerkung:** Not all transmit policies may be 802.3ad compliant, particularly in regards to the packet misordering requirements of section 43.2.4 of the 802.3ad standard.

---

- **active-backup** - Active-backup policy: Only one slave in the bond is active. A different slave becomes active if, and only if, the active slave fails. The bond's MAC address is externally visible on only one port (network adapter) to avoid confusing the switch.

When a failover occurs in active-backup mode, bonding will issue one or more gratuitous ARPs on the newly active slave. One gratuitous ARP is issued for the bonding master interface and each VLAN interfaces configured above it, provided that the interface has at least one IP address configured. Gratuitous ARPs issued for VLAN interfaces are tagged with the appropriate VLAN id.

This mode provides fault tolerance. The `primary` option, documented below, affects the behavior of this mode.

- **broadcast** - Broadcast policy: transmits everything on all slave interfaces.

This mode provides fault tolerance.

- **round-robin** - Round-robin policy: Transmit packets in sequential order from the first available slave through the last.

This mode provides load balancing and fault tolerance.

- **transmit-load-balance** - Adaptive transmit load balancing: channel bonding that does not require any special switch support.

Incoming traffic is received by the current slave. If the receiving slave fails, another slave takes over the MAC address of the failed receiving slave.

- **adaptive-load-balance** - Adaptive load balancing: includes transmit-load-balance plus receive load balancing for IPV4 traffic, and does not require any special switch support. The receive load balancing is achieved by ARP negotiation. The bonding driver intercepts the ARP Replies sent by the local system on their way out and overwrites the source hardware address with the unique hardware address of one of the slaves in the bond such that different peers use different hardware addresses for the server.

Receive traffic from connections created by the server is also balanced. When the local system sends an ARP Request the bonding driver copies and saves the peer's IP information from the ARP packet. When the ARP Reply arrives from the peer, its hardware address is retrieved and the bonding driver initiates an ARP reply to this peer assigning it to one of the slaves in the bond. A problematic outcome of using ARP negotiation for balancing is that each time that an ARP request is broadcast it uses the hardware address of the bond. Hence, peers learn the hardware address of the bond and the balancing of receive traffic collapses to the current slave. This is handled by sending updates (ARP Replies) to all the peers with their individually assigned hardware address such that the traffic is redistributed. Receive traffic is also redistributed when a new slave is added to the bond and when an inactive slave is re-activated. The receive load is distributed sequentially (round robin) among the group of highest speed slaves in the bond.

When a link is reconnected or a new slave joins the bond the receive traffic is redistributed among all active slaves in the bond by initiating ARP Replies with the selected MAC address to each of the clients. The updelay parameter (detailed below) must be set to a value equal or greater than the switch's forwarding delay so that the ARP Replies sent to the peers will not be blocked by the switch.

- **xor-hash** - XOR policy: Transmit based on the selected transmit hash policy. The default policy is a simple [(source MAC address XOR'd with destination MAC address XOR packet type ID) modulo slave count]. Alternate transmit policies may be selected via the **hash-policy** option, described below.

This mode provides load balancing and fault tolerance.

**set interfaces bonding <interface> min-links <0-16>**

Specifies the minimum number of links that must be active before asserting carrier. It is similar to the Cisco EtherChannel min-links feature. This allows setting the minimum number of member ports that must be up (link-up state) before marking the bond device as up (carrier on). This is useful for situations where higher level services such as clustering want to ensure a minimum number of low bandwidth links are active before switchover.

This option only affects 802.3ad mode.

The default value is 0. This will cause the carrier to be asserted (for 802.3ad mode) whenever there is an active aggregator, regardless of the number of available links in that aggregator.

---

**Bemerkung:** Because an aggregator cannot be active without at least one available link, setting this option to 0 or to 1 has the exact same effect.

---

**set interfaces bonding <interface> lacp-rate <slow|fast>**

Option specifying the rate in which we'll ask our link partner to transmit LACPDU packets in 802.3ad mode.

This option only affects 802.3ad mode.

- **slow:** Request partner to transmit LACPDU every 30 seconds
- **fast:** Request partner to transmit LACPDU every 1 second

The default value is slow.

**set interfaces bonding <interface> system-mac <mac address>**

This option allow to specifies the 802.3ad system MAC address. You can set a random mac-address that can be used for these LACPDU exchanges.

**set interfaces bonding <interface> hash-policy <policy>**

- **layer2** - Uses XOR of hardware MAC addresses and packet type ID field to generate the hash. The formula is

```
hash = source MAC XOR destination MAC XOR packet type ID
slave number = hash modulo slave count
```

This algorithm will place all traffic to a particular network peer on the same slave.

This algorithm is 802.3ad compliant.

- **layer2+3** - This policy uses a combination of layer2 and layer3 protocol information to generate the hash. Uses XOR of hardware MAC addresses and IP addresses to generate the hash. The formula is:

```
hash = source MAC XOR destination MAC XOR packet type ID
hash = hash XOR source IP XOR destination IP
hash = hash XOR (hash RSHIFT 16)
hash = hash XOR (hash RSHIFT 8)
```

And then hash is reduced modulo slave count.

If the protocol is IPv6 then the source and destination addresses are first hashed using `ipv6_addr_hash`.

This algorithm will place all traffic to a particular network peer on the same slave. For non-IP traffic, the formula is the same as for the layer2 transmit hash policy.

This policy is intended to provide a more balanced distribution of traffic than layer2 alone, especially in environments where a layer3 gateway device is required to reach most destinations.

This algorithm is 802.3ad compliant.

- **layer3+4** - This policy uses upper layer protocol information, when available, to generate the hash. This allows for traffic to a particular network peer to span multiple slaves, although a single connection will not span multiple slaves.

The formula for unfragmented TCP and UDP packets is

```
hash = source port, destination port (as in the header)
hash = hash XOR source IP XOR destination IP
hash = hash XOR (hash RSHIFT 16)
hash = hash XOR (hash RSHIFT 8)
```

And then hash is reduced modulo slave count.

If the protocol is IPv6 then the source and destination addresses are first hashed using `ipv6_addr_hash`.

For fragmented TCP or UDP packets and all other IPv4 and IPv6 protocol traffic, the source and destination port information is omitted. For non-IP traffic, the formula is the same as for the layer2 transmit hash policy.

This algorithm is not fully 802.3ad compliant. A single TCP or UDP conversation containing both fragmented and unfragmented packets will see packets striped across two interfaces. This may result in out of order delivery. Most traffic types will not meet these criteria, as TCP rarely fragments traffic, and most UDP traffic is not involved in extended conversations. Other implementations of 802.3ad may or may not tolerate this noncompliance.

#### **set interfaces bonding <interface> primary <interface>**

An *<interface>* specifying which slave is the primary device. The specified device will always be the active slave while it is available. Only when the primary is off-line will alternate devices be used. This is useful when one slave is preferred over another, e.g., when one slave has higher throughput than another.

The primary option is only valid for active-backup, transmit-load-balance, and adaptive-load-balance mode.

**set interfaces bonding <interface> arp-monitor interval <time>**

Specifies the ARP link monitoring *<time>* in seconds.

The ARP monitor works by periodically checking the slave devices to determine whether they have sent or received traffic recently (the precise criteria depends upon the bonding mode, and the state of the slave). Regular traffic is generated via ARP probes issued for the addresses specified by the `arp-monitor target` option.

If ARP monitoring is used in an etherchannel compatible mode (modes round-robin and xor-hash), the switch should be configured in a mode that evenly distributes packets across all links. If the switch is configured to distribute the packets in an XOR fashion, all replies from the ARP targets will be received on the same link which could cause the other team members to fail.

A value of 0 disables ARP monitoring. The default value is 0.

**set interfaces bonding <interface> arp-monitor target <address>**

Specifies the IP addresses to use as ARP monitoring peers when `arp-monitor interval` option is > 0. These are the targets of the ARP request sent to determine the health of the link to the targets.

Multiple target IP addresses can be specified. At least one IP address must be given for ARP monitoring to function.

The maximum number of targets that can be specified is 16. The default value is no IP address.

## VLAN

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

**set interfaces bonding <interface> vif <vlan-id>**

Create a new VLAN interface on interface *<interface>* using the VLAN number provided via *<vlan-id>*.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

---

**Bemerkung:** Only 802.1Q-tagged packets are accepted on Ethernet vifs.

---

**set interfaces bonding <interface> vif <vlan-id> address <address | dhcp | dhcpv6>**

Configure interface *<interface>* with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.

- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
- /config/scripts/dhcp-client/post-hooks.d/

Example:

```
set interfaces bonding bond0 vif 10 address 192.0.2.1/24
set interfaces bonding bond0 vif 10 address 2001:db8::1/64
set interfaces bonding bond0 vif 10 address dhcp
set interfaces bonding bond0 vif 10 address dhcpv6
```

#### **set interfaces bonding <interface> vif <vlan-id> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces bonding bond0 vif 10 description 'This is an awesome interface_
↳running on VyOS'
```

#### **set interfaces bonding <interface> vif <vlan-id> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces bonding bond0 vif 10 disable
```

#### **set interfaces bonding <interface> vif <vlan-id> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces bonding bond0 vif 10 disable-link-detect
```

#### **set interfaces bonding <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces bonding bond0 vif 10 mac '00:01:02:03:04:05'
```

#### **set interfaces bonding <interface> vif <vlan-id> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces bonding bond0 vif 10 mtu 1600
```

```
set interfaces bonding <interface> vif <vlan-id> ip adjust-mss <mss | clamp-mss-to-pmtu>
```

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

```
set interfaces bonding <interface> vif <vlan-id> ip arp-cache-timeout
```

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces bonding bond0 vif 10 ip arp-cache-timeout 180
```

```
set interfaces bonding <interface> vif <vlan-id> ip disable-arp-filter
```

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces bonding bond0 vif 10 ip disable-arp-filter
```

```
set interfaces bonding <interface> vif <vlan-id> ip disable-forwarding
```

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces bonding bond0 vif 10 ip disable-forwarding
```

```
set interfaces bonding <interface> vif <vlan-id> ip enable-directed-broadcast
```

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces bonding bond0 vif 10 ip enable-directed-broadcast
```

```
set interfaces bonding <interface> vif <vlan-id> ip enable-arp-accept
```

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces bonding bond0 vif 10 ip enable-arp-accept
```

#### **set interfaces bonding <interface> vif <vlan-id> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces bonding bond0 vif 10 ip enable-arp-announce
```

#### **set interfaces bonding <interface> vif <vlan-id> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces bonding bond0 vif 10 ip enable-arp-ignore
```

#### **set interfaces bonding <interface> vif <vlan-id> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces bonding bond0 vif 10 ip enable-proxy-arp
```

#### **set interfaces bonding <interface> vif <vlan-id> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces bonding <interface> vif <vlan-id> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**set interfaces bonding <interface> vif <vlan-id> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces bonding bond0 vif 10 ipv6 address autoconf
```

**set interfaces bonding <interface> vif <vlan-id> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces bonding bond0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces bonding <interface> vif <vlan-id> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces bonding bond0 vif 10 ipv6 address no-default-link-local
```

**set interfaces bonding <interface> vif <vlan-id> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces bonding bond0 vif 10 ipv6 disable-forwarding
```

```
set interfaces bonding <interface> vif <vlan-id> ipv6 adjust-mss <mss |
clamp-mss-to-pmtu>
```

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally ‚do not try to send me packets bigger than this value‘.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

```
set interfaces bonding <interface> vif <vlan-id> ipv6 accept-dad <1-3>
```

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces bonding bond0 vif 10 ipv6 accept-dad 2
```

```
set interfaces bonding <interface> vif <vlan-id> ipv6 dup-addr-detect-transmits <n>
```

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces bonding bond0 vif 10 ipv6 dup-addr-detect-transmits 5
```

```
set interfaces bonding <interface> vif <vlan-id> vrf <vrf>
```

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces bonding bond0 vif 10 vrf red
```

## DHCP(v6)

```
set interfaces bonding <interface> vif <vlan-id> dhcp-options client-id <description>
```

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ‚client identifier‘ option. If the client supplies a ‚client identifier‘, the client MUST use the same ‚client identifier‘ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces bonding bond0 vif 10 dhcp-options client-id 'foo-bar'
```

**set interfaces bonding <interface> vif <vlan-id> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces bonding bond0 vif 10 dhcp-options host-name 'VyOS'
```

**set interfaces bonding <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces bonding bond0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces bonding <interface> vif <vlan-id> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces bonding bond0 vif 10 dhcp-options no-default-route
```

**set interfaces bonding <interface> vif <vlan-id> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces bonding bond0 vif 10 dhcp-options default-route-distance 220
```

**set interfaces bonding <interface> vif <vlan-id> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces bonding bond0 vif 10 dhcp-options reject 192.168.100.0/24
```

**set interfaces bonding <interface> vif <vlan-id> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces bonding bond0 vif 10 dhcp-options user-class VyOS
```

**set interfaces bonding <interface> vif <vlan-id> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces bonding bond0 vif 10 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

#### **set interfaces bonding <interface> vif <vlan-id> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces bonding bond0 vif 10 dhcpv6-options no-release
```

#### **set interfaces bonding <interface> vif <vlan-id> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces bonding bond0 vif 10 dhcpv6-options parameters-only
```

#### **set interfaces bonding <interface> vif <vlan-id> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces bonding bond0 vif 10 dhcpv6-options rapid-commit
```

#### **set interfaces bonding <interface> vif <vlan-id> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces bonding bond0 vif 10 dhcpv6-options temporary
```

### **DHCPv6 Prefix Delegation (PD)**

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

#### **set interfaces bonding <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces bonding bond0 vif 10 dhcpv6-options pd 0 length 56
```

#### **set interfaces bonding <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces bonding bond0 vif 10 dhcpv6-options pd 0 interface eth8 address 65534
```

**set interfaces bonding <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces bonding bond0 vif 10 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## Port Mirror (SPAN)

SPAN port mirroring can copy the inbound/outbound traffic of the interface to the specified interface, usually the interface can be connected to some special equipment, such as behavior control system, intrusion detection system and traffic collector, and can copy all related traffic from this port. The benefit of mirroring the traffic is that the application is isolated from the source traffic and so application processing does not affect the traffic or the system performance.

VyOS uses the *mirror* option to configure port mirroring. The configuration is divided into 2 different directions. Destination ports should be configured for different traffic directions.

**set interfaces bondinging <interface> mirror ingress <monitor-interface>**

Configure port mirroring for *interface* inbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the inbound traffic of *bond1* port to *eth3*

```
set interfaces bondinging bond1 mirror ingress eth3
```

**set interfaces bondinging <interface> mirror egress <monitor-interface>**

Configure port mirroring for *interface* outbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the outbound traffic of *bond1* port to *eth3*

```
set interfaces bondinging bond1 mirror egress eth3
```

## EVPN Multihoming

All-Active Multihoming is used for redundancy and load sharing. Servers are attached to two or more PEs and the links are bonded (link-aggregation). This group of server links is referred to as an ES (Ethernet Segment).

An Ethernet Segment can be configured by specifying a system-MAC and a local discriminator or a complete ESINAME against the bond interface on the PE.

**set interfaces bonding <interface> evpn es-id <<1-16777215|10-byte ID>**

**set interfaces bonding <interface> evpn es-sys-mac <xx:xx:xx:xx:xx:xx>**

The sys-mac and local discriminator are used for generating a 10-byte, Type-3 Ethernet Segment ID. ESNAME is a 10-byte, Type-0 Ethernet Segment ID - „00:AA:BB:CC:DD:EE:FF:GG:HH:II“.

Type-1 (EAD-per-ES and EAD-per-EVI) routes are used to advertise the locally attached ESs and to learn off remote ESs in the network. Local Type-2/MAC-IP routes are also advertised with a destination ESI allowing for MAC-IP syncing between Ethernet Segment peers. Reference: RFC 7432, RFC 8365

EVPN-MH is intended as a replacement for MLAG or Anycast VTEPs. In multihoming each PE has a unique VTEP address which requires the introduction of a new dataplane construct, MAC-ECMP. Here a MAC/FDB entry can point to a list of remote PEs/VTEPs.

**set interfaces bonding <interface> evpn es-df-pref <1-65535>**

Type-4 (ESR) routes are used for Designated Forwarder (DF) election. DFs forward BUM traffic received via the overlay network. This implementation uses a preference based DF election specified by draft-ietf-bess-evpn-pref-df.

The DF preference is configurable per-ES.

BUM traffic is rxed via the overlay by all PEs attached to a server but only the DF can forward the de-capsulated traffic to the access port. To accommodate that non-DF filters are installed in the dataplane to drop the traffic.

Similarly traffic received from ES peers via the overlay cannot be forwarded to the server. This is split-horizon-filtering with local bias.

**set interfaces bonding <interface> evpn uplink**

When all the underlay links go down the PE no longer has access to the VxLAN +overlay. To prevent blackholing of traffic the server/ES links are protodowned on the PE.

A link can be setup for uplink tracking via the following example:

```
set interfaces bonding bond0 evpn uplink
```

## Example

The following configuration on VyOS applies to all following 3rd party vendors. It creates a bond with two links and VLAN 10, 100 on the bonded interfaces with a per VIF IPv4 address.

```
# Create bonding interface bond0 with 802.3ad LACP
set interfaces bonding bond0 hash-policy 'layer2'
set interfaces bonding bond0 mode '802.3ad'

# Add the required vlans and IPv4 addresses on them
set interfaces bonding bond0 vif 10 address 192.168.0.1/24
set interfaces bonding bond0 vif 100 address 10.10.10.1/24

# Add the member interfaces to the bonding interface
set interfaces bonding bond0 member interface eth1
set interfaces bonding bond0 member interface eth2
```

**Bemerkung:** If you happen to run this in a virtual environment like by EVE-NG you need to ensure your VyOS NIC is set to use the e1000 driver. Using the default virtio-net-pci or the vmxnet3 driver will not work. ICMP messages will not be properly processed. They are visible on the virtual wire but will not make it fully up the networking stack.

You can check your NIC driver by issuing `show interfaces ethernet eth0 physical | grep -i driver`

## Cisco Catalyst

Assign member interfaces to PortChannel

```
interface GigabitEthernet1/0/23
description VyOS eth1
channel-group 1 mode active
!
interface GigabitEthernet1/0/24
description VyOS eth2
channel-group 1 mode active
!
```

A new interface becomes present Port-channel1, all configuration like allowed VLAN interfaces, STP will happen here.

```
interface Port-channel1
description LACP Channel for VyOS
switchport trunk encapsulation dot1q
switchport trunk allowed vlan 10,100
switchport mode trunk
spanning-tree portfast trunk
!
```

## Juniper EX Switch

For a headstart you can use the below example on how to build a bond with two interfaces from VyOS to a Juniper EX Switch system.

```
# Create aggregated ethernet device with 802.3ad LACP and port speeds of 10gbit/s
set interfaces ae0 aggregated-ether-options link-speed 10g
set interfaces ae0 aggregated-ether-options lacp active

# Create layer 2 on the aggregated ethernet device with trunking for our vlans
set interfaces ae0 unit 0 family ethernet-switching port-mode trunk

# Add the required vlans to the device
set interfaces ae0 unit 0 family ethernet-switching vlan members 10
set interfaces ae0 unit 0 family ethernet-switching vlan members 100

# Add the two interfaces to the aggregated ethernet device, in this setup both
# ports are on the same switch (switch 0, module 1, port 0 and 1)
set interfaces xe-0/1/0 ether-options 802.3ad ae0
set interfaces xe-0/1/1 ether-options 802.3ad ae0

# But this can also be done with multiple switches in a stack, a virtual
# chassis on Juniper (switch 0 and switch 1, module 1, port 0 on both switches)
set interfaces xe-0/1/0 ether-options 802.3ad ae0
set interfaces xe-1/1/0 ether-options 802.3ad ae0
```

## Aruba/HP

For a headstart you can use the below example on how to build a bond,port-channel with two interfaces from VyOS to a Aruba/HP 2510G switch.

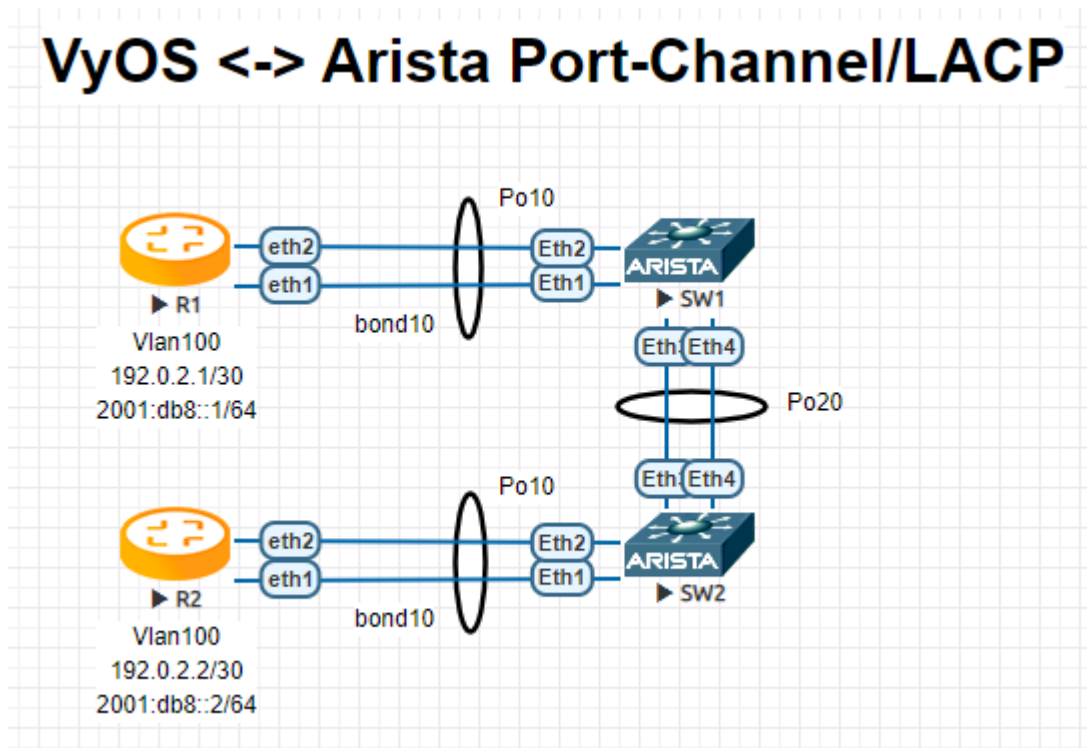

```
# Create trunk with 2 member interfaces (interface 1 and 2) and LACP
trunk 1-2 Trk1 LACP

# Add the required vlans to the trunk
vlan 10 tagged Trk1
vlan 100 tagged Trk1
```

## Arista EOS

When utilizing VyOS in an environment with Arista gear you can use this blue print as an initial setup to get an LACP bond / port-channel operational between those two devices.

Lets assume the following topology:

### R1

```
interfaces {
    bonding bond10 {
        hash-policy layer3+4
        member {
            interface eth1
            interface eth2
        }
    }
}
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

mode 802.3ad
vif 100 {
    address 192.0.2.1/30
    address 2001:db8::1/64
}

```

**R2**

```

interfaces {
    bonding bond10 {
        hash-policy layer3+4
        member {
            interface eth1
            interface eth2
        }
        mode 802.3ad
        vif 100 {
            address 192.0.2.2/30
            address 2001:db8::2/64
        }
    }
}

```

**SW1**

```

!
vlan 100
    name F00
!
interface Port-Channel10
    switchport trunk allowed vlan 100
    switchport mode trunk
    spanning-tree portfast
!
interface Port-Channel20
    switchport mode trunk
    no spanning-tree portfast auto
    spanning-tree portfast network
!
interface Ethernet1
    channel-group 10 mode active
!
interface Ethernet2
    channel-group 10 mode active
!
interface Ethernet3
    channel-group 20 mode active
!
interface Ethernet4
    channel-group 20 mode active
!

```

**SW2**

```

!
vlan 100
    name F00
!
interface Port-Channel10
    switchport trunk allowed vlan 100
    switchport mode trunk
    spanning-tree portfast
!
interface Port-Channel20
    switchport mode trunk
    no spanning-tree portfast auto
    spanning-tree portfast network
!
interface Ethernet1
    channel-group 10 mode active
!
interface Ethernet2
    channel-group 10 mode active
!
interface Ethernet3
    channel-group 20 mode active
!
interface Ethernet4
    channel-group 20 mode active
!

```

**Bemerkung:** When using EVE-NG to lab this environment ensure you are using e1000 as the desired driver for your VyOS network interfaces. When using the regular virtio network driver no LACP PDUs will be sent by VyOS thus the port-channel will never become active!

## Operation

### show interfaces bonding

Show brief interface information.

```

vyos@vyos:~$ show interfaces bonding
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
bond0          -               u/u  my-sw1 int 23 and 24
bond0.10       192.168.0.1/24  u/u  office-net
bond0.100      10.10.10.1/24   u/u  management-net

```

### show interfaces bonding <interface>

Show detailed information on given <interface>

```

vyos@vyos:~$ show interfaces bonding bond5
bond5: <NO-CARRIER,BROADCAST,MULTICAST,MASTER,UP> mtu 1500 qdisc noqueue state DOWN_

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

→group default qlen 1000
  link/ether 00:50:56:bf:ef:aa brd ff:ff:ff:ff:ff:ff

## 8.4.2 Bridge

A Bridge is a way to connect two Ethernet segments together in a protocol independent way. Packets are forwarded based on Ethernet address, rather than IP address (like a router). Since forwarding is done at Layer 2, all protocols can go transparently through a bridge. The Linux bridge code implements a subset of the ANSI/IEEE 802.1d standard.

**Bemerkung:** Spanning Tree Protocol is not enabled by default in VyOS. *STP Parameter* can be easily enabled if needed.

### Configuration

#### Common interface configuration

**set interfaces bridge <interface> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
- /config/scripts/dhcp-client/post-hooks.d/

Example:

```
set interfaces bridge br0 address 192.0.2.1/24
set interfaces bridge br0 address 2001:db8::1/64
set interfaces bridge br0 address dhcp
set interfaces bridge br0 address dhcpv6
```

**set interfaces bridge <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces bridge br0 description 'This is an awesome interface running on VyOS'
```

**set interfaces bridge <interface> disable**

Disable given *<interface>*. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces bridge br0 disable
```

### **set interfaces bridge <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces bridge br0 disable-flow-control
```

### **set interfaces bridge <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces bridge br0 disable-link-detect
```

### **set interfaces bridge <interface> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given *<interface>*.

Example:

```
set interfaces bridge br0 mac '00:01:02:03:04:05'
```

### **set interfaces bridge <interface> mtu <mtu>**

Configure MTU on given *<interface>*. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces bridge br0 mtu 1600
```

### **set interfaces bridge <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

#### **set interfaces bridge <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces bridge br0 ip arp-cache-timeout 180
```

#### **set interfaces bridge <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces bridge br0 ip disable-arp-filter
```

#### **set interfaces bridge <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces bridge br0 ip disable-forwarding
```

#### **set interfaces bridge <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces bridge br0 ip enable-directed-broadcast
```

#### **set interfaces bridge <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces bridge br0 ip enable-arp-accept
```

**set interfaces bridge <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces bridge br0 ip enable-arp-announce
```

**set interfaces bridge <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces bridge br0 ip enable-arp-ignore
```

**set interfaces bridge <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces bridge br0 ip enable-proxy-arp
```

**set interfaces bridge <interface> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces bridge <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

#### **set interfaces bridge <interface> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces bridge br0 ipv6 address autoconf
```

#### **set interfaces bridge <interface> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces bridge br0 ipv6 address eui64 2001:db8:beef::/64
```

#### **set interfaces bridge <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces bridge br0 ipv6 address no-default-link-local
```

#### **set interfaces bridge <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces bridge br0 ipv6 disable-forwarding
```

#### **set interfaces bridge <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces bridge <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces bridge br0 ipv6 accept-dad 2
```

**set interfaces bridge <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces bridge br0 ipv6 dup-addr-detect-transmits 5
```

**set interfaces bridge <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces bridge br0 vrf red
```

## DHCP(v6)

**set interfaces bridge <interface> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ‚client identifier‘ option. If the client supplies a ‚client identifier‘, the client MUST use the same ‚client identifier‘ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces bridge br0 dhcp-options client-id 'foo-bar'
```

**set interfaces bridge <interface> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces bridge br0 dhcp-options host-name 'VyOS'
```

### **set interfaces bridge <interface> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces bridge br0 dhcp-options vendor-class-id 'VyOS'
```

### **set interfaces bridge <interface> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces bridge br0 dhcp-options no-default-route
```

### **set interfaces bridge <interface> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces bridge br0 dhcp-options default-route-distance 220
```

### **set interfaces bridge <interface> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces bridge br0 dhcp-options reject 192.168.100.0/24
```

### **set interfaces bridge <interface> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces bridge br0 dhcp-options user-class VyOS
```

### **set interfaces bridge <interface> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces bridge br0 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

### **set interfaces bridge <interface> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces bridge br0 dhcpv6-options no-release
```

#### **set interfaces bridge <interface> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces bridge br0 dhcpv6-options parameters-only
```

#### **set interfaces bridge <interface> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces bridge br0 dhcpv6-options rapid-commit
```

#### **set interfaces bridge <interface> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces bridge br0 dhcpv6-options temporary
```

### **DHCPv6 Prefix Delegation (PD)**

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

#### **set interfaces bridge <interface> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces bridge br0 dhcpv6-options pd 0 length 56
```

#### **set interfaces bridge <interface> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces bridge br0 dhcpv6-options pd 0 interface eth8 address 65534
```

#### **set interfaces bridge <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces bridge br0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## Member Interfaces

**set interfaces bridge <interface> member interface <member>**

Assign <member> interface to bridge <interface>. A completion helper will help you with all allowed interfaces which can be bridged. This includes *Ethernet*, *Bond / Link Aggregation*, *L2TPv3*, *OpenVPN*, *VXLAN*, *WLAN/WIFI - Wireless LAN*, *Tunnel* and *GENEVE*.

**set interfaces bridge <interface> member interface <member> priority <priority>**

Configure individual bridge port <priority>.

Each bridge has a relative priority and cost. Each interface is associated with a port (number) in the STP code. Each has a priority and a cost, that is used to decide which is the shortest path to forward a packet. The lowest cost path is always used unless the other path is down. If you have multiple bridges and interfaces then you may need to adjust the priorities to achieve optimum performance.

**set interfaces bridge <interface> member interface <member> cost <cost>**

Path <cost> value for Spanning Tree Protocol. Each interface in a bridge could have a different speed and this value is used when deciding which link to use. Faster interfaces should have lower costs.

## Bridge Options

**set interfaces bridge <interface> aging <time>**

MAC address aging <time> in seconds (default: 300).

**set interfaces bridge <interface> max-age <time>**

Bridge maximum aging <time> in seconds (default: 20).

If another bridge in the spanning tree does not send out a hello packet for a long period of time, it is assumed to be dead.

**set interfaces bridge <interface> igmp querier**

Enable IGMP and MLD querier.

**set interfaces bridge <interface> igmp snooping**

Enable IGMP and MLD snooping.

## STP Parameter

STP (Spanning Tree Protocol) is a network protocol that builds a loop-free logical topology for Ethernet networks. The basic function of STP is to prevent bridge loops and the broadcast radiation that results from them. Spanning tree also allows a network design to include backup links providing fault tolerance if an active link fails.

**set interfaces bridge <interface> stp**

Enable spanning tree protocol. STP is disabled by default.

**set interfaces bridge <interface> forwarding-delay <delay>**

Spanning Tree Protocol forwarding <delay> in seconds (default: 15).

The forwarding delay time is the time spent in each of the listening and learning states before the Forwarding state is entered. This delay is so that when a new bridge comes onto a busy network it looks at some traffic before participating.

**set interfaces bridge <interface> hello-time <interval>**

Spanning Tree Protocol hello advertisement <interval> in seconds (default: 2).

Periodically, a hello packet is sent out by the Root Bridge and the Designated Bridges. Hello packets are used to communicate information about the topology throughout the entire Bridged Local Area Network.

## VLAN

### Enable VLAN-Aware Bridge

**set interfaces bridge <interface> enable-vlan**

To activate the VLAN aware bridge, you must activate this setting to use VLAN settings for the bridge

**set interfaces bridge <interface> protocol <802.1ad|802.1q>**

Define used ethertype of bridge interface.

Ethertype 0x8100 is used for 802.1q and ethertype 0x88a8 is used for 802.1ad.

The default is 802.1q.

### VLAN Options

---

**Bemerkung:** It is not valid to use the *vif 1* option for VLAN aware bridges because VLAN aware bridges assume that all unlabeled packets belong to the default VLAN 1 member and that the VLAN ID of the bridge's parent interface is always 1

---

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

**set interfaces bridge <interface> vif <vlan-id>**

Create a new VLAN interface on interface <interface> using the VLAN number provided via <vlan-id>.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

---

**Bemerkung:** Only 802.1Q-tagged packets are accepted on Ethernet vifs.

---

**set interfaces bridge <interface> vif <vlan-id> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
  - /config/scripts/dhcp-client/post-hooks.d/
- 

Example:

```
set interfaces bridge br0 vif 10 address 192.0.2.1/24
set interfaces bridge br0 vif 10 address 2001:db8::1/64
set interfaces bridge br0 vif 10 address dhcp
set interfaces bridge br0 vif 10 address dhcpv6
```

**set interfaces bridge <interface> vif <vlan-id> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces bridge br0 vif 10 description 'This is an awesome interface running
↪ on VyOS'
```

**set interfaces bridge <interface> vif <vlan-id> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces bridge br0 vif 10 disable
```

**set interfaces bridge <interface> vif <vlan-id> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces bridge br0 vif 10 disable-link-detect
```

**set interfaces bridge <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces bridge br0 vif 10 mac '00:01:02:03:04:05'
```

**set interfaces bridge <interface> vif <vlan-id> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces bridge br0 vif 10 mtu 1600
```

**set interfaces bridge <interface> vif <vlan-id> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces bridge <interface> vif <vlan-id> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces bridge br0 vif 10 ip arp-cache-timeout 180
```

**set interfaces bridge <interface> vif <vlan-id> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces bridge br0 vif 10 ip disable-arp-filter
```

#### **set interfaces bridge <interface> vif <vlan-id> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces bridge br0 vif 10 ip disable-forwarding
```

#### **set interfaces bridge <interface> vif <vlan-id> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces bridge br0 vif 10 ip enable-directed-broadcast
```

#### **set interfaces bridge <interface> vif <vlan-id> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces bridge br0 vif 10 ip enable-arp-accept
```

#### **set interfaces bridge <interface> vif <vlan-id> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces bridge br0 vif 10 ip enable-arp-announce
```

#### **set interfaces bridge <interface> vif <vlan-id> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces bridge br0 vif 10 ip enable-arp-ignore
```

#### **set interfaces bridge <interface> vif <vlan-id> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces bridge br0 vif 10 ip enable-proxy-arp
```

### **set interfaces bridge <interface> vif <vlan-id> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

### **set interfaces bridge <interface> vif <vlan-id> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

### **set interfaces bridge <interface> vif <vlan-id> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces bridge br0 vif 10 ipv6 address autoconf
```

**set interfaces bridge <interface> vif <vlan-id> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces bridge br0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces bridge <interface> vif <vlan-id> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces bridge br0 vif 10 ipv6 address no-default-link-local
```

**set interfaces bridge <interface> vif <vlan-id> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces bridge br0 vif 10 ipv6 disable-forwarding
```

**set interfaces bridge <interface> vif <vlan-id> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces bridge <interface> vif <vlan-id> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces bridge br0 vif 10 ipv6 accept-dad 2
```

**set interfaces bridge <interface> vif <vlan-id> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces bridge br0 vif 10 ipv6 dup-addr-detect-transmits 5
```

**set interfaces bridge <interface> vif <vlan-id> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces bridge br0 vif 10 vrf red
```

## DHCP(v6)

**set interfaces bridge <interface> vif <vlan-id> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier‘ option. If the client supplies a ,client identifier‘, the client MUST use the same ,client identifier‘ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options client-id 'foo-bar'
```

**set interfaces bridge <interface> vif <vlan-id> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options host-name 'VyOS'
```

**set interfaces bridge <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces bridge <interface> vif <vlan-id> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options no-default-route
```

**set interfaces bridge <interface> vif <vlan-id> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options default-route-distance 220
```

**set interfaces bridge <interface> vif <vlan-id> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces bridge br0 vif 10 dhcp-options reject 192.168.100.0/24
```

**set interfaces bridge <interface> vif <vlan-id> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options user-class VyOS
```

**set interfaces bridge <interface> vif <vlan-id> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces bridge br0 vif 10 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

**set interfaces bridge <interface> vif <vlan-id> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces bridge br0 vif 10 dhcpv6-options no-release
```

**set interfaces bridge <interface> vif <vlan-id> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces bridge br0 vif 10 dhcpv6-options parameters-only
```

**set interfaces bridge <interface> vif <vlan-id> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces bridge br0 vif 10 dhcpv6-options rapid-commit
```

**set interfaces bridge <interface> vif <vlan-id> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces bridge br0 vif 10 dhcpv6-options temporary
```

### DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

```
set interfaces bridge <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>
```

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces bridge br0 vif 10 dhcpv6-options pd 0 length 56
```

```
set interfaces bridge <interface> vif <vlan-id> dhcpv6-options pd <id> interface
<delegatee> address <address>
```

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces bridge br0 vif 10 dhcpv6-options pd 0 interface eth8 address 65534
```

```
set interfaces bridge <interface> vif <vlan-id> dhcpv6-options pd <id> interface
<delegatee> sla-id <id>
```

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces bridge br0 vif 10 dhcpv6-options pd 0 interface eth8 sla-id 1
```

```
set interfaces bridge <interface> member interface <member> native-vlan <vlan-id>
```

Set the native VLAN ID flag of the interface. When a data packet without a VLAN tag enters the port, the data packet will be forced to add a tag of a specific vlan id. When the vlan id flag flows out, the tag of the vlan id will be stripped

Example: Set *eth0* member port to be native VLAN 2

```
set interfaces bridge br1 member interface eth0 native-vlan 2
```

```
set interfaces bridge <interface> member interface <member> allowed-vlan <vlan-id>
```

Allows specific VLAN IDs to pass through the bridge member interface. This can either be an individual VLAN id or a range of VLAN ids delimited by a hyphen.

Example: Set *eth0* member port to be allowed VLAN 4

```
set interfaces bridge br1 member interface eth0 allowed-vlan 4
```

Example: Set *eth0* member port to be allowed VLAN 6-8

```
set interfaces bridge br1 member interface eth0 allowed-vlan 6-8
```

## Port Mirror (SPAN)

SPAN port mirroring can copy the inbound/outbound traffic of the interface to the specified interface, usually the interface can be connected to some special equipment, such as behavior control system, intrusion detection system and traffic collector, and can copy all related traffic from this port. The benefit of mirroring the traffic is that the application is isolated from the source traffic and so application processing does not affect the traffic or the system performance.

VyOS uses the *mirror* option to configure port mirroring. The configuration is divided into 2 different directions. Destination ports should be configured for different traffic directions.

**set interfaces bridge <interface> mirror ingress <monitor-interface>**

Configure port mirroring for *interface* inbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the inbound traffic of *br1* port to *eth3*

```
set interfaces bridge br1 mirror ingress eth3
```

**set interfaces bridge <interface> mirror egress <monitor-interface>**

Configure port mirroring for *interface* outbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the outbound traffic of *br1* port to *eth3*

```
set interfaces bridge br1 mirror egress eth3
```

## Examples

### Create a basic bridge

Creating a bridge interface is very simple. In this example, we will have:

- A bridge named *br100*
- Member interfaces *eth1* and VLAN 10 on interface *eth2*
- Enable STP
- Bridge answers on IP address 192.0.2.1/24 and 2001:db8::ffff/64

```
set interfaces bridge br100 address 192.0.2.1/24
set interfaces bridge br100 address 2001:db8::ffff/64
set interfaces bridge br100 member interface eth1
set interfaces bridge br100 member interface eth2.10
set interfaces bridge br100 stp
```

This results in the active configuration:

```
vyos@vyos# show interfaces bridge br100
address 192.0.2.1/24
address 2001:db8::ffff/64
member {
    interface eth1 {
    }
    interface eth2.10 {
    }
}
stp
```

## Using VLAN aware Bridge

An example of creating a VLAN-aware bridge is as follows:

- A bridge named *br100*
- The member interface *eth1* is a trunk that allows VLAN 10 to pass
- VLAN 10 on member interface *eth2* (ACCESS mode)
- Enable STP
- Bridge answers on IP address 192.0.2.1/24 and 2001:db8::ffff/64

```
set interfaces bridge br100 enable-vlan
set interfaces bridge br100 member interface eth1 allowed-vlan 10
set interfaces bridge br100 member interface eth2 native-vlan 10
set interfaces bridge br100 vif 10 address 192.0.2.1/24
set interfaces bridge br100 vif 10 address 2001:db8::ffff/64
set interfaces bridge br100 stp
```

This results in the active configuration:

```
vyos@vyos# show interfaces bridge br100
enable-vlan
member {
    interface eth1 {
        allowed-vlan 10
    }
    interface eth2 {
        native-vlan 10
    }
}
stp
vif 10 {
    address 192.0.2.1/24
    address 2001:db8::ffff/64
}
```

## Using the operation mode command to view Bridge Information

### show bridge

The *show bridge* operational command can be used to display configured bridges:

```
vyos@vyos:~$ show bridge
3: eth1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master br0 state forwarding
priority 32 cost 100
4: eth2: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master br0 state forwarding
priority 32 cost 100
```

### show bridge <name> fdb

Show bridge <name> fdb displays the current forwarding table:

```
vyos@vyos:~$ show bridge br0 fdb
50:00:00:08:00:01 dev eth1 vlan 20 master br0 permanent
50:00:00:08:00:01 dev eth1 vlan 10 master br0 permanent
50:00:00:08:00:01 dev eth1 master br0 permanent
33:33:00:00:00:01 dev eth1 self permanent
33:33:00:00:00:02 dev eth1 self permanent
01:00:5e:00:00:01 dev eth1 self permanent
50:00:00:08:00:02 dev eth2 vlan 20 master br0 permanent
50:00:00:08:00:02 dev eth2 vlan 10 master br0 permanent
50:00:00:08:00:02 dev eth2 master br0 permanent
33:33:00:00:00:01 dev eth2 self permanent
33:33:00:00:00:02 dev eth2 self permanent
01:00:5e:00:00:01 dev eth2 self permanent
33:33:00:00:00:01 dev br0 self permanent
33:33:00:00:00:02 dev br0 self permanent
33:33:ff:08:00:01 dev br0 self permanent

```

### show bridge <name> mdb

Show bridge <name> mdb displays the current multicast group membership table. The table is populated by IGMP and MLD snooping in the bridge driver automatically.

```
vyos@vyos:~$ show bridge br0 mdb
dev br0 port br0 grp ff02::1:ff00:0 temp vid 1
dev br0 port br0 grp ff02::2 temp vid 1
dev br0 port br0 grp ff02::1:ff08:1 temp vid 1
dev br0 port br0 grp ff02::6a temp vid 1
```

### 8.4.3 Dummy

The dummy interface is really a little exotic, but rather useful nevertheless. Dummy interfaces are much like the *Loopback* interface, except you can have as many as you want.

---

**Bemerkung:** Dummy interfaces can be used as interfaces that always stay up (in the same fashion to loopbacks in Cisco IOS), or for testing purposes.

---

---

**Hinweis:** On systems with multiple redundant uplinks and routes, it's a good idea to use a dedicated address for management and dynamic routing protocols. However, assigning that address to a physical link is risky: if that link goes down, that address will become inaccessible. A common solution is to assign the management address to a loopback or a dummy interface and advertise that address via all physical links, so that it's reachable through any of them. Since in Linux-based systems, there can be only one loopback interface, it's better to use a dummy interface for that purpose, since they can be added, removed, and taken up and down independently.

---

## Configuration

### Common interface configuration

**set interfaces dummy <interface> address <address>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces dummy dum0 address 192.0.2.1/24
set interfaces dummy dum0 address 2001:db8::1/64
```

**set interfaces dummy <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces dummy dum0 description 'This is an awesome interface running on VyOS'
```

**set interfaces dummy <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces dummy dum0 disable
```

**set interfaces dummy <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a *VRF*, please check this for additional information.

Example:

```
set interfaces dummy dum0 vrf red
```

## Operation

### show interfaces dummy

Show brief interface information.

```
vyos@vyos:~$ show interfaces dummy
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
dum0           172.18.254.201/32  u/u
```

### show interfaces dummy <interface>

Show detailed information on given <interface>

```
vyos@vyos:~$ show interfaces dummy dum0
dum0: <BROADCAST,NOARP,UP,LOWER_UP> mtu 1500 qdisc noqueue state UNKNOWN group_
↳default qlen 1000
    link/ether 26:7c:8e:bc:fc:f5 brd ff:ff:ff:ff:ff:ff
    inet 172.18.254.201/32 scope global dum0
        valid_lft forever preferred_lft forever
    inet6 fe80::247c:8eff:febc:fcf5/64 scope link
        valid_lft forever preferred_lft forever

    RX:  bytes    packets    errors    dropped    overrun    mcast
         0         0         0         0         0         0
    TX:  bytes    packets    errors    dropped    carrier    collisions
    1369707      4267         0         0         0         0
```

## 8.4.4 Ethernet

This will be the most widely used interface on a router carrying traffic to the real world.

## Configuration

### Common interface configuration

#### set interfaces ethernet <interface> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
- /config/scripts/dhcp-client/post-hooks.d/

Example:

```
set interfaces ethernet eth0 address 192.0.2.1/24
set interfaces ethernet eth0 address 2001:db8::1/64
set interfaces ethernet eth0 address dhcp
set interfaces ethernet eth0 address dhcpv6
```

### **set interfaces ethernet <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces ethernet eth0 description 'This is an awesome interface running on
↳ VyOS'
```

### **set interfaces ethernet <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces ethernet eth0 disable
```

### **set interfaces ethernet <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces ethernet eth0 disable-flow-control
```

### **set interfaces ethernet <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces ethernet eth0 disable-link-detect
```

**set interfaces ethernet <interface> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces ethernet eth0 mac '00:01:02:03:04:05'
```

**set interfaces ethernet <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces ethernet eth0 mtu 1600
```

**set interfaces ethernet <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces ethernet <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces ethernet eth0 ip arp-cache-timeout 180
```

**set interfaces ethernet <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces ethernet eth0 ip disable-arp-filter
```

**set interfaces ethernet <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces ethernet eth0 ip disable-forwarding
```

#### **set interfaces ethernet <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces ethernet eth0 ip enable-directed-broadcast
```

#### **set interfaces ethernet <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces ethernet eth0 ip enable-arp-accept
```

#### **set interfaces ethernet <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces ethernet eth0 ip enable-arp-announce
```

#### **set interfaces ethernet <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces ethernet eth0 ip enable-arp-ignore
```

#### **set interfaces ethernet <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces ethernet eth0 ip enable-proxy-arp
```

### set interfaces ethernet <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

### set interfaces ethernet <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

### set interfaces ethernet <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces ethernet eth0 ipv6 address autoconf
```

### set interfaces ethernet <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces ethernet eth0 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces ethernet <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces ethernet eth0 ipv6 address no-default-link-local
```

**set interfaces ethernet <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces ethernet eth0 ipv6 disable-forwarding
```

**set interfaces ethernet <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces ethernet <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces ethernet eth0 ipv6 accept-dad 2
```

**set interfaces ethernet <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces ethernet eth0 ipv6 dup-addr-detect-transmits 5
```

**set interfaces ethernet <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces ethernet eth0 vrf red
```

**DHCP(v6)**

**set interfaces ethernet <interface> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier‘ option. If the client supplies a ,client identifier‘, the client MUST use the same ,client identifier‘ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces ethernet eth0 dhcp-options client-id 'foo-bar'
```

**set interfaces ethernet <interface> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces ethernet eth0 dhcp-options host-name 'VyOS'
```

**set interfaces ethernet <interface> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces ethernet eth0 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces ethernet <interface> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces ethernet eth0 dhcp-options no-default-route
```

**set interfaces ethernet <interface> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces ethernet eth0 dhcp-options default-route-distance 220
```

**set interfaces ethernet <interface> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces ethernet eth0 dhcp-options reject 192.168.100.0/24
```

#### **set interfaces ethernet <interface> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces ethernet eth0 dhcp-options user-class VyOS
```

#### **set interfaces ethernet <interface> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces ethernet eth0 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

#### **set interfaces ethernet <interface> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces ethernet eth0 dhcpv6-options no-release
```

#### **set interfaces ethernet <interface> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces ethernet eth0 dhcpv6-options parameters-only
```

#### **set interfaces ethernet <interface> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces ethernet eth0 dhcpv6-options rapid-commit
```

#### **set interfaces ethernet <interface> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces ethernet eth0 dhcpv6-options temporary
```

### **DHCPv6 Prefix Delegation (PD)**

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

#### **set interfaces ethernet <interface> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces ethernet eth0 dhcpv6-options pd 0 length 56
```

**set interfaces ethernet <interface> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces ethernet eth0 dhcpv6-options pd 0 interface eth8 address 65534
```

**set interfaces ethernet <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces ethernet eth0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## Ethernet options

**set interfaces ethernet <interface> duplex <auto | full | half>**

Configure physical interface duplex setting.

- auto - interface duplex setting is auto-negotiated
- full - always use full-duplex
- half - always use half-duplex

VyOS default will be *auto*.

**set interfaces ethernet <interface> speed <auto | 10 | 100 | 1000 | 2500 | 5000 | 10000 | 25000 | 40000 | 50000 | 100000>**

Configure physical interface speed setting.

- auto - interface speed is auto-negotiated
- 10 - 10 MBit/s
- 100 - 100 MBit/s
- 1000 - 1 GBit/s
- 2500 - 2.5 GBit/s
- 5000 - 5 GBit/s
- 10000 - 10 GBit/s

- 25000 - 25 GBit/s
- 40000 - 40 GBit/s
- 50000 - 50 GBit/s
- 100000 - 100 GBit/s

VyOS default will be *auto*.

## Offloading

**set interfaces ethernet <interface> offload <gro | gso | lro | rps | sg | tso>**

Enable different types of hardware offloading on the given NIC.

LRO (Large Receive Offload) is a technique designed to boost the efficiency of how your computer's network interface card (NIC) processes incoming network traffic. Typically, network data arrives in smaller chunks called packets. Processing each packet individually consumes CPU (central processing unit) resources. Lots of small packets can lead to a performance bottleneck. Instead of handing the CPU each packet as it comes in, LRO instructs the NIC to combine multiple incoming packets into a single, larger packet. This larger packet is then passed to the CPU for processing.

---

**Bemerkung:** Under some circumstances, LRO is known to modify the packet headers of forwarded traffic, which breaks the end-to-end principle of computer networking. LRO is also only able to offload TCP segments encapsulated in IPv4 packets. Due to these limitations, it is recommended to use GRO (Generic Receive Offload) where possible. More information on the limitations of LRO can be found here: <https://lwn.net/Articles/358910/>

---

GSO (Generic Segmentation Offload) is a pure software offload that is meant to deal with cases where device drivers cannot perform the offloads described above. What occurs in GSO is that a given skbuff will have its data broken out over multiple skbuffs that have been resized to match the MSS provided via `skb_shinfo()->gso_size`.

Before enabling any hardware segmentation offload a corresponding software offload is required in GSO. Otherwise it becomes possible for a frame to be re-routed between devices and end up being unable to be transmitted.

GRO (Generic receive offload) is the complement to GSO. Ideally any frame assembled by GRO should be segmented to create an identical sequence of frames using GSO, and any sequence of frames segmented by GSO should be able to be reassembled back to the original by GRO. The only exception to this is IPv4 ID in the case that the DF bit is set for a given IP header. If the value of the IPv4 ID is not sequentially incrementing it will be altered so that it is when a frame assembled via GRO is segmented via GSO.

RPS (Receive Packet Steering) is logically a software implementation of RSS (Receive Side Scaling). Being in software, it is necessarily called later in the datapath. Whereas RSS selects the queue and hence CPU that will run the hardware interrupt handler, RPS selects the CPU to perform protocol processing above the interrupt handler. This is accomplished by placing the packet on the desired CPU's backlog queue and waking up the CPU for processing. RPS has some advantages over RSS:

- it can be used with any NIC
- software filters can easily be added to hash over new protocols
- it does not increase hardware device interrupt rate, although it does introduce inter-processor interrupts (IPIs)

---

**Bemerkung:** In order to use TSO/LRO with VMXNET3 adapters, the SG offloading option must also be enabled.

---

## Authentication (EAPoL)

EAP (Extensible Authentication Protocol) over LAN (EAPoL) is a network port authentication protocol used in IEEE 802.1X (Port Based Network Access Control) developed to give a generic network sign-on to access network resources.

EAPoL comes with an identify option. We automatically use the interface MAC address as identity parameter.

**set interfaces ethernet <interface> eapol ca-certificate <name>**

Set the name of the SSL CA (Certificate Authority) PKI entry used for authentication of the remote side. If an intermediate CA certificate is specified, then all parent CA certificates that exist in the PKI, such as the root CA or additional intermediate CAs, will automatically be used during certificate validation to ensure that the full chain of trust is available.

Example:

```
set pki ca eapol-server-intermediate-ca <Server intermediate CA contents>
set pki ca eapol-server-root-ca <Server root CA contents>
set interfaces ethernet eth0 eapol ca-certificate eapol-server-intermediate-ca
```

**set interfaces ethernet <interface> eapol certificate <name>**

Set the name of the x509 client keypair used to authenticate against the 802.1x system. All parent CA certificates of the client certificate, such as intermediate and root CAs, will be sent as part of the EAP-TLS handshake.

Example:

```
set pki ca eapol-client-intermediate-ca <Client intermediate CA contents>
set pki ca eapol-client-root-ca <Client root CA contents>
set pki certificate eapol-client certificate <Client certificate contents>
set pki certificate eapol-client private key <Client private key contents>
set interfaces ethernet eth0 eapol certificate eapol-client
```

## EVPN Multihoming

Uplink/Core tracking.

**set interfaces ethernet <interface> evpn uplink**

When all the underlay links go down the PE no longer has access to the VxLAN +overlay. To prevent blackholing of traffic the server/ES links are protodowned on the PE.

A link can be setup for uplink tracking via the following example:

```
set interfaces ethernet eth0 evpn uplink
```

## VLAN

### Regular VLANs (802.1q)

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

**set interfaces ethernet <interface> vif <vlan-id>**

Create a new VLAN interface on interface <interface> using the VLAN number provided via <vlan-id>.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

---

**Bemerkung:** Only 802.1Q-tagged packets are accepted on Ethernet vifs.

---

**set interfaces ethernet <interface> vif <vlan-id> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
  - /config/scripts/dhcp-client/post-hooks.d/
- 

Example:

```
set interfaces ethernet eth0 vif 10 address 192.0.2.1/24
set interfaces ethernet eth0 vif 10 address 2001:db8::1/64
set interfaces ethernet eth0 vif 10 address dhcp
set interfaces ethernet eth0 vif 10 address dhcpv6
```

**set interfaces ethernet <interface> vif <vlan-id> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces ethernet eth0 vif 10 description 'This is an awesome interface.
↳ running on VyOS'
```

**set interfaces ethernet <interface> vif <vlan-id> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces ethernet eth0 vif 10 disable
```

### **set interfaces ethernet <interface> vif <vlan-id> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces ethernet eth0 vif 10 disable-link-detect
```

### **set interfaces ethernet <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces ethernet eth0 vif 10 mac '00:01:02:03:04:05'
```

### **set interfaces ethernet <interface> vif <vlan-id> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces ethernet eth0 vif 10 mtu 1600
```

### **set interfaces ethernet <interface> vif <vlan-id> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

### **set interfaces ethernet <interface> vif <vlan-id> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces ethernet eth0 vif 10 ip arp-cache-timeout 180
```

### **set interfaces ethernet <interface> vif <vlan-id> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned

by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces ethernet eth0 vif 10 ip disable-arp-filter
```

#### **set interfaces ethernet <interface> vif <vlan-id> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces ethernet eth0 vif 10 ip disable-forwarding
```

#### **set interfaces ethernet <interface> vif <vlan-id> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces ethernet eth0 vif 10 ip enable-directed-broadcast
```

#### **set interfaces ethernet <interface> vif <vlan-id> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces ethernet eth0 vif 10 ip enable-arp-accept
```

#### **set interfaces ethernet <interface> vif <vlan-id> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces ethernet eth0 vif 10 ip enable-arp-announce
```

#### **set interfaces ethernet <interface> vif <vlan-id> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces ethernet eth0 vif 10 ip enable-arp-ignore
```

### **set interfaces ethernet <interface> vif <vlan-id> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces ethernet eth0 vif 10 ip enable-proxy-arp
```

### **set interfaces ethernet <interface> vif <vlan-id> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

### **set interfaces ethernet <interface> vif <vlan-id> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

### **set interfaces ethernet <interface> vif <vlan-id> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 address autoconf
```

**set interfaces ethernet <interface> vif <vlan-id> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces ethernet <interface> vif <vlan-id> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 address no-default-link-local
```

**set interfaces ethernet <interface> vif <vlan-id> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 disable-forwarding
```

**set interfaces ethernet <interface> vif <vlan-id> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value `clamp-mss-to-pmtu` can be used to automatically set the proper value.

**set interfaces ethernet <interface> vif <vlan-id> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 accept-dad 2
```

**set interfaces ethernet <interface> vif <vlan-id> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 dup-addr-detect-transmits 5
```

**set interfaces ethernet <interface> vif <vlan-id> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces ethernet eth0 vif 10 vrf red
```

## DHCP(v6)

**set interfaces ethernet <interface> vif <vlan-id> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier' option. If the client supplies a ,client identifier', the client MUST use the same ,client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options client-id 'foo-bar'
```

**set interfaces ethernet <interface> vif <vlan-id> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options host-name 'VyOS'
```

**set interfaces ethernet <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces ethernet <interface> vif <vlan-id> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options no-default-route
```

**set interfaces ethernet <interface> vif <vlan-id> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options default-route-distance 220
```

**set interfaces ethernet <interface> vif <vlan-id> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options reject 192.168.100.0/24
```

**set interfaces ethernet <interface> vif <vlan-id> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options user-class VyOS
```

**set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces ethernet eth0 vif 10 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

**set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options no-release
```

**set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options parameters-only
```

**set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options rapid-commit
```

**set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options temporary
```

### DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

**set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces ethernet eth0 vif 10 dhcpv6-options pd 0 length 56
```

**set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options pd 0 interface eth8 address 65534
```

**set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:fff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:fff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## QinQ (802.1ad)

IEEE 802.1ad was an Ethernet networking standard informally known as QinQ as an amendment to IEEE standard 802.1q VLAN interfaces as described above. 802.1ad was incorporated into the base 802.1q standard in 2011. The technique is also known as provider bridging, Stacked VLANs, or simply QinQ or Q-in-Q. „Q-in-Q“ can for supported devices apply to C-tag stacking on C-tag (Ethernet Type = 0x8100).

The original 802.1q specification allows a single Virtual Local Area Network (VLAN) header to be inserted into an Ethernet frame. QinQ allows multiple VLAN tags to be inserted into a single frame, an essential capability for implementing Metro Ethernet network topologies. Just as QinQ extends 802.1Q, QinQ itself is extended by other Metro Ethernet protocols.

In a multiple VLAN header context, out of convenience the term „VLAN tag“ or just „tag“ for short is often used in place of „802.1q VLAN header“. QinQ allows multiple VLAN tags in an Ethernet frame; together these tags constitute a tag stack. When used in the context of an Ethernet frame, a QinQ frame is a frame that has 2 VLAN 802.1q headers (double-tagged).

In VyOS the terms `vif-s` and `vif-c` stand for the ethertype tags that are used.

The inner tag is the tag which is closest to the payload portion of the frame. It is officially called C-TAG (customer tag, with ethertype 0x8100). The outer tag is the one closer/closest to the Ethernet header, its name is S-TAG (service tag with Ethernet Type = 0x88a8).

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
- /config/scripts/dhcp-client/post-hooks.d/

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 address 192.0.2.1/24
set interfaces ethernet eth0 vif-s 1000 vif-c 20 address 2001:db8::1/64
set interfaces ethernet eth0 vif-s 1000 vif-c 20 address dhcp
set interfaces ethernet eth0 vif-s 1000 vif-c 20 address dhcpv6
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 description 'This is an awesome
↪ interface running on VyOS'
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 disable
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 disable-link-detect
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> mac  
<xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 mac '00:01:02:03:04:05'
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 mtu 1600
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally ,do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip arp-cache-timeout 180
```

### **set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip disable-arp-filter
```

### **set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip disable-forwarding
```

### **set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip enable-directed-broadcast
```

### **set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip enable-arp-accept
```

### **set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our

subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip enable-arp-announce
```

### **set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip enable-arp-ignore
```

### **set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip enable-proxy-arp
```

### **set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

### **set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 address autoconf
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 address eui64 2001:db8:beef::/
↪ 64
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 address no-default-link-local
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 disable-forwarding
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 adjust-mss <mss> | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

```
set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 accept-dad <1-3>
```

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 accept-dad 2
```

```
set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6
dup-addr-detect-transmits <n>
```

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 dup-addr-detect-transmits 5
```

```
set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> vrf <vrf>
```

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 vrf red
```

## DHCP(v6)

```
set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options
client-id <description>
```

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier' option. If the client supplies a ,client identifier', the client MUST use the same ,client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options client-id 'foo-bar'
```

```
set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options
host-name <hostname>
```

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options host-name 'VyOS'
```

```
set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options
vendor-class-id <vendor-id>
```

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options no-default-route
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options default-route-
→ distance 220
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options reject 192.168.100.0/
→ 24
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options user-class VyOS
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options no-release
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options parameters-only
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options rapid-commit
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options temporary
```

### DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 length 56
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 interface eth8.
↪address 65534
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:fff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:fff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 interface eth8.
↪sla-id 1
```

## Port Mirror (SPAN)

SPAN port mirroring can copy the inbound/outbound traffic of the interface to the specified interface, usually the interface can be connected to some special equipment, such as behavior control system, intrusion detection system and traffic collector, and can copy all related traffic from this port. The benefit of mirroring the traffic is that the application is isolated from the source traffic and so application processing does not affect the traffic or the system performance.

VyOS uses the *mirror* option to configure port mirroring. The configuration is divided into 2 different directions. Destination ports should be configured for different traffic directions.

**set interfaces ethernet <interface> mirror ingress <monitor-interface>**

Configure port mirroring for *interface* inbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the inbound traffic of *eth1* port to *eth3*

```
set interfaces ethernet eth1 mirror ingress eth3
```

**set interfaces ethernet <interface> mirror egress <monitor-interface>**

Configure port mirroring for *interface* outbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the outbound traffic of *eth1* port to *eth3*

```
set interfaces ethernet eth1 mirror egress eth3
```

## Operation

**show interfaces ethernet**

Show brief interface information.

```
vyos@vyos:~$ show interfaces ethernet
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
```

## 8.4.5 GENEVE

GENEVE (Generic Network Virtualization Encapsulation) supports all of the capabilities of VXLAN (Virtual Extensible LAN), NVGRE (Network Virtualization using Generic Routing Encapsulation), and STT (Stateless Transport Tunneling) and was designed to overcome their perceived limitations. Many believe GENEVE could eventually replace these earlier formats entirely.

GENEVE is designed to support network virtualization use cases, where tunnels are typically established to act as a backplane between the virtual switches residing in hypervisors, physical switches, or middleboxes or other appliances. An arbitrary IP network can be used as an underlay although Clos networks - A technique for composing network fabrics larger than a single switch while maintaining non-blocking bandwidth across connection points. ECMP is used to divide traffic across the multiple links and switches that constitute the fabric. Sometimes termed „leaf and spine“ or „fat tree“ topologies.

Geneve Header:

```

+++++
|Ver| Opt Len |O|C|   Rsvd. |           Protocol Type           |
+++++
|           Virtual Network Identifier (VNI)           |   Reserved   |
+++++
|           Variable Length Options           |
+++++

```

## Configuration

### Common interface configuration

**set interfaces geneve <interface> address <address>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces geneve gnv0 address 192.0.2.1/24
set interfaces geneve gnv0 address 2001:db8::1/64
```

### **set interfaces geneve <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces geneve gnv0 description 'This is an awesome interface running on VyOS
↪ '
```

### **set interfaces geneve <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces geneve gnv0 disable
```

### **set interfaces geneve <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces geneve gnv0 disable-flow-control
```

### **set interfaces geneve <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces geneve gnv0 disable-link-detect
```

### **set interfaces geneve <interface> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces geneve gnv0 mac '00:01:02:03:04:05'
```

### **set interfaces geneve <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces geneve gnv0 mtu 1600
```

**set interfaces geneve <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces geneve <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces geneve gnv0 ip arp-cache-timeout 180
```

**set interfaces geneve <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces geneve gnv0 ip disable-arp-filter
```

**set interfaces geneve <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces geneve gnv0 ip disable-forwarding
```

**set interfaces geneve <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces geneve gnv0 ip enable-directed-broadcast
```

### **set interfaces geneve <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces geneve gnv0 ip enable-arp-accept
```

### **set interfaces geneve <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces geneve gnv0 ip enable-arp-announce
```

### **set interfaces geneve <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces geneve gnv0 ip enable-arp-ignore
```

### **set interfaces geneve <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces geneve gnv0 ip enable-proxy-arp
```

### **set interfaces geneve <interface> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces geneve <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**set interfaces geneve <interface> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces geneve gnv0 ipv6 address autoconf
```

**set interfaces geneve <interface> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces geneve gnv0 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces geneve <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces geneve gnv0 ipv6 address no-default-link-local
```

**set interfaces geneve <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces geneve gnv0 ipv6 disable-forwarding
```

**set interfaces geneve <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally ,do not try to send me packets bigger than this value‘.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces geneve <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces geneve gnv0 ipv6 accept-dad 2
```

**set interfaces geneve <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces geneve gnv0 ipv6 dup-addr-detect-transmits 5
```

**set interfaces geneve <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces geneve gnv0 vrf red
```

## GENEVE options

**set interfaces geneve gnv0 remote <address>**

Configure GENEVE tunnel far end/remote tunnel endpoint.

**set interfaces geneve gnv0 vni <vni>**

VNI (Virtual Network Identifier) is an identifier for a unique element of a virtual network. In many situations this may represent an L2 segment, however, the control plane defines the forwarding semantics of decapsulated packets. The VNI MAY be used as part of ECMP forwarding decisions or MAY be used as a mechanism to distinguish between overlapping address spaces contained in the encapsulated packet when load balancing across CPUs.

## 8.4.6 L2TPv3

Layer 2 Tunnelling Protocol Version 3 is an IETF standard related to L2TP that can be used as an alternative protocol to *MPLS* for encapsulation of multiprotocol Layer 2 communications traffic over IP networks. Like L2TP, L2TPv3 provides a pseudo-wire service but is scaled to fit carrier requirements.

L2TPv3 can be regarded as being to MPLS what IP is to ATM: a simplified version of the same concept, with much of the same benefit achieved at a fraction of the effort, at the cost of losing some technical features considered less important in the market.

In the case of L2TPv3, the features lost are teletraffic engineering features considered important in MPLS. However, there is no reason these features could not be re-engineered in or on top of L2TPv3 in later products.

The protocol overhead of L2TPv3 is also significantly bigger than MPLS.

L2TPv3 is described in [RFC 3931](#).

## Configuration

### Common interface configuration

**set interfaces l2tpv3 <interface> address <address>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces l2tpv3 l2tpeth0 address 192.0.2.1/24
set interfaces l2tpv3 l2tpeth0 address 2001:db8::1/64
```

**set interfaces l2tpv3 <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces l2tpv3 l2tpeth0 description 'This is an awesome interface running on
↳ VyOS'
```

**set interfaces l2tpv3 <interface> disable**

Disable given *<interface>*. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces l2tpv3 l2tpeth0 disable
```

### **set interfaces l2tpv3 <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces l2tpv3 l2tpeth0 disable-flow-control
```

### **set interfaces l2tpv3 <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces l2tpv3 l2tpeth0 disable-link-detect
```

### **set interfaces l2tpv3 <interface> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given *<interface>*.

Example:

```
set interfaces l2tpv3 l2tpeth0 mac '00:01:02:03:04:05'
```

### **set interfaces l2tpv3 <interface> mtu <mtu>**

Configure MTU on given *<interface>*. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces l2tpv3 l2tpeth0 mtu 1600
```

### **set interfaces l2tpv3 <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

#### **set interfaces l2tpv3 <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces l2tpv3 l2tpeth0 ip arp-cache-timeout 180
```

#### **set interfaces l2tpv3 <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces l2tpv3 l2tpeth0 ip disable-arp-filter
```

#### **set interfaces l2tpv3 <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces l2tpv3 l2tpeth0 ip disable-forwarding
```

#### **set interfaces l2tpv3 <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces l2tpv3 l2tpeth0 ip enable-directed-broadcast
```

#### **set interfaces l2tpv3 <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces l2tpv3 l2tpeth0 ip enable-arp-accept
```

**set interfaces l2tpv3 <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces l2tpv3 l2tpeth0 ip enable-arp-announce
```

**set interfaces l2tpv3 <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces l2tpv3 l2tpeth0 ip enable-arp-ignore
```

**set interfaces l2tpv3 <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces l2tpv3 l2tpeth0 ip enable-proxy-arp
```

**set interfaces l2tpv3 <interface> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces l2tpv3 <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

#### **set interfaces l2tpv3 <interface> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 address autoconf
```

#### **set interfaces l2tpv3 <interface> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 address eui64 2001:db8:beef::/64
```

#### **set interfaces l2tpv3 <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 address no-default-link-local
```

#### **set interfaces l2tpv3 <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 disable-forwarding
```

#### **set interfaces l2tpv3 <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces l2tpv3 <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 accept-dad 2
```

**set interfaces l2tpv3 <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 dup-addr-detect-transmits 5
```

**set interfaces l2tpv3 <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces l2tpv3 l2tpeth0 vrf red
```

## L2TPv3 options

**set interfaces l2tpv3 <interface> encapsulation <udp | ip>**

Set the encapsulation type of the tunnel. Valid values for encapsulation are: udp, ip.

This defaults to UDP

**set interfaces l2tpv3 <interface> source-address <address>**

Set the IP address of the local interface to be used for the tunnel.

This address must be the address of a local interface. It may be specified as an IPv4 address or an IPv6 address.

**set interfaces l2tpv3 <interface> remote <address>**

Set the IP address of the remote peer. It may be specified as an IPv4 address or an IPv6 address.

**set interfaces l2tpv3 <interface> session-id <id>**

Set the session id, which is a 32-bit integer value. Uniquely identifies the session being created. The value used must match the peer\_session\_id value being used at the peer.

**set interfaces l2tpv3 <interface> peer-session-id <id>**

Set the peer-session-id, which is a 32-bit integer value assigned to the session by the peer. The value used must match the session\_id value being used at the peer.

**set interfaces l2tpv3 <interface> tunnel-id <id>**

Set the tunnel id, which is a 32-bit integer value. Uniquely identifies the tunnel into which the session will be created.

**set interfaces l2tpv3 <interface> peer-tunnel-id <id>**

Set the tunnel id, which is a 32-bit integer value. Uniquely identifies the tunnel into which the session will be created.

## Example

### Over IP

```
# show interfaces l2tpv3
l2tpv3 l2tpeth10 {
    address 192.168.37.1/27
    encapsulation ip
    source-address 192.0.2.1
    peer-session-id 100
    peer-tunnel-id 200
    remote 203.0.113.24
    session-id 100
    tunnel-id 200
}
```

The inverse configuration has to be applied to the remote side.

### Over UDP

UDP mode works better with NAT:

- Set source-address to your local IP (LAN).
- Add a forwarding rule matching UDP port on your internet router.

```
# show interfaces l2tpv3
l2tpv3 l2tpeth10 {
    address 192.168.37.1/27
    destination-port 9001
    encapsulation udp
    source-address 192.0.2.1
    peer-session-id 100
    peer-tunnel-id 200
}
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

remote 203.0.113.24
session-id 100
source-port 9000
tunnel-id 200
}

```

To create more than one tunnel, use distinct UDP ports.

### Over IPsec, L2 VPN (bridge)

This is the LAN extension use case. The eth0 port of the distant VPN peers will be directly connected like if there was a switch between them.

IPsec:

```

set vpn ipsec authentication psk <pre-shared-name> id '%any'
set vpn ipsec authentication psk <pre-shared-name> secret <pre-shared-key>
set vpn ipsec interface <VPN-interface>
set vpn ipsec esp-group test-ESP-1 lifetime '3600'
set vpn ipsec esp-group test-ESP-1 mode 'transport'
set vpn ipsec esp-group test-ESP-1 pfs 'enable'
set vpn ipsec esp-group test-ESP-1 proposal 1 encryption 'aes128'
set vpn ipsec esp-group test-ESP-1 proposal 1 hash 'sha1'
set vpn ipsec ike-group test-IKE-1 key-exchange 'ikev1'
set vpn ipsec ike-group test-IKE-1 lifetime '3600'
set vpn ipsec ike-group test-IKE-1 proposal 1 dh-group '5'
set vpn ipsec ike-group test-IKE-1 proposal 1 encryption 'aes128'
set vpn ipsec ike-group test-IKE-1 proposal 1 hash 'sha1'
set vpn ipsec site-to-site peer <connection-name> authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer <connection-name> connection-type 'initiate'
set vpn ipsec site-to-site peer <connection-name> ike-group 'test-IKE-1'
set vpn ipsec site-to-site peer <connection-name> ikev2-reauth 'inherit'
set vpn ipsec site-to-site peer <connection-name> local-address <local-ip>
set vpn ipsec site-to-site peer <connection-name> tunnel 1 esp-group 'test-ESP-1'
set vpn ipsec site-to-site peer <connection-name> tunnel 1 protocol 'l2tp'

```

Bridge:

```

set interfaces bridge br0 description 'L2 VPN Bridge'
# remote side in this example:
# set interfaces bridge br0 address '172.16.30.18/30'
set interfaces bridge br0 address '172.16.30.17/30'
set interfaces bridge br0 member interface eth0
set interfaces ethernet eth0 description 'L2 VPN Physical port'

```

L2TPv3:

```

set interfaces bridge br0 member interface 'l2tpeth0'
set interfaces l2tpv3 l2tpeth0 description 'L2 VPN Tunnel'
set interfaces l2tpv3 l2tpeth0 destination-port '5000'
set interfaces l2tpv3 l2tpeth0 encapsulation 'ip'
set interfaces l2tpv3 l2tpeth0 source-address <local-ip>

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set interfaces l2tpv3 l2tpeth0 mtu '1500'
set interfaces l2tpv3 l2tpeth0 peer-session-id '110'
set interfaces l2tpv3 l2tpeth0 peer-tunnel-id '10'
set interfaces l2tpv3 l2tpeth0 remote <peer-ip>
set interfaces l2tpv3 l2tpeth0 session-id '110'
set interfaces l2tpv3 l2tpeth0 source-port '5000'
set interfaces l2tpv3 l2tpeth0 tunnel-id '10'

```

## 8.4.7 Loopback

The loopback networking interface is a virtual network device implemented entirely in software. All traffic sent to it „loops back“ and just targets services on your local machine.

---

**Bemerkung:** There can only be one loopback lo interface on the system. If you need multiple interfaces, please use the *Dummy* interface type.

---

---

**Hinweis:** A loopback interface is always up, thus it could be used for management traffic or as source/destination for and IGP (Interior Gateway Protocol) like *BGP* so your internal BGP link is not dependent on physical link states and multiple routes can be chosen to the destination. A *Dummy* Interface should always be preferred over a *Loopback* interface.

---

## Configuration

### Common interface configuration

**set interfaces loopback <interface> address <address>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```

set interfaces loopback lo address 192.0.2.1/24
set interfaces loopback lo address 2001:db8::1/64

```

**set interfaces loopback <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```

set interfaces loopback lo description 'This is an awesome interface running on VyOS
↪ '

```

## Operation

### show interfaces loopback

Show brief interface information.

```
vyos@vyos:~$ show interfaces loopback
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
lo             127.0.0.1/8     u/u
              ::1/128
```

### show interfaces loopback lo

Show detailed information on the given loopback interface *lo*.

```
vyos@vyos:~$ show interfaces loopback lo
lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN group default qlen
→1000
  link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
  inet 127.0.0.1/8 scope host lo
    valid_lft forever preferred_lft forever
  inet6 ::1/128 scope host
    valid_lft forever preferred_lft forever

  RX:  bytes    packets   errors   dropped   overrun    mcast

```

## 8.4.8 MACsec

MACsec is an IEEE standard (IEEE 802.1AE) for MAC security, introduced in 2006. It defines a way to establish a protocol independent connection between two hosts with data confidentiality, authenticity and/or integrity, using GCM-AES-128. MACsec operates on the Ethernet layer and as such is a layer 2 protocol, which means it's designed to secure traffic within a layer 2 network, including DHCP or ARP requests. It does not compete with other security solutions such as IPsec (layer 3) or TLS (layer 4), as all those solutions are used for their own specific use cases.

## Configuration

### Common interface configuration

**set interfaces macsec <interface> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
- /config/scripts/dhcp-client/post-hooks.d/

Example:

```
set interfaces macsec macsec0 address 192.0.2.1/24
set interfaces macsec macsec0 address 2001:db8::1/64
set interfaces macsec macsec0 address dhcp
set interfaces macsec macsec0 address dhcpv6
```

#### **set interfaces macsec <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces macsec macsec0 description 'This is an awesome interface running on
↳ VyOS'
```

#### **set interfaces macsec <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces macsec macsec0 disable
```

#### **set interfaces macsec <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces macsec macsec0 disable-flow-control
```

#### **set interfaces macsec <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces macsec macsec0 disable-link-detect
```

**set interfaces macsec <interface> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces macsec macsec0 mac '00:01:02:03:04:05'
```

**set interfaces macsec <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces macsec macsec0 mtu 1600
```

**set interfaces macsec <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces macsec <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces macsec macsec0 ip arp-cache-timeout 180
```

**set interfaces macsec <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces macsec macsec0 ip disable-arp-filter
```

**set interfaces macsec <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces macsec macsec0 ip disable-forwarding
```

#### **set interfaces macsec <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces macsec macsec0 ip enable-directed-broadcast
```

#### **set interfaces macsec <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces macsec macsec0 ip enable-arp-accept
```

#### **set interfaces macsec <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces macsec macsec0 ip enable-arp-announce
```

#### **set interfaces macsec <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces macsec macsec0 ip enable-arp-ignore
```

#### **set interfaces macsec <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces macsec macsec0 ip enable-proxy-arp
```

### set interfaces macsec <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

### set interfaces macsec <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

### set interfaces macsec <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces macsec macsec0 ipv6 address autoconf
```

### set interfaces macsec <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces macsec macsec0 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces macsec <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces macsec macsec0 ipv6 address no-default-link-local
```

**set interfaces macsec <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces macsec macsec0 ipv6 disable-forwarding
```

**set interfaces macsec <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces macsec <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces macsec macsec0 ipv6 accept-dad 2
```

**set interfaces macsec <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces macsec macsec0 ipv6 dup-addr-detect-transmits 5
```

**set interfaces macsec <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces macsec macsec0 vrf red
```

**DHCP(v6)**

**set interfaces macsec <interface> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier' option. If the client supplies a ,client identifier', the client MUST use the same ,client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces macsec macsec0 dhcp-options client-id 'foo-bar'
```

**set interfaces macsec <interface> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces macsec macsec0 dhcp-options host-name 'VyOS'
```

**set interfaces macsec <interface> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces macsec macsec0 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces macsec <interface> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces macsec macsec0 dhcp-options no-default-route
```

**set interfaces macsec <interface> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces macsec macsec0 dhcp-options default-route-distance 220
```

**set interfaces macsec <interface> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces macsec macsec0 dhcp-options reject 192.168.100.0/24
```

#### **set interfaces macsec <interface> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces macsec macsec0 dhcp-options user-class VyOS
```

#### **set interfaces macsec <interface> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces macsec macsec0 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

#### **set interfaces macsec <interface> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces macsec macsec0 dhcpv6-options no-release
```

#### **set interfaces macsec <interface> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces macsec macsec0 dhcpv6-options parameters-only
```

#### **set interfaces macsec <interface> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces macsec macsec0 dhcpv6-options rapid-commit
```

#### **set interfaces macsec <interface> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces macsec macsec0 dhcpv6-options temporary
```

### **DHCPv6 Prefix Delegation (PD)**

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

#### **set interfaces macsec <interface> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces macsec macsec0 dhcpv6-options pd 0 length 56
```

**set interfaces macsec <interface> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces macsec macsec0 dhcpv6-options pd 0 interface eth8 address 65534
```

**set interfaces macsec <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces macsec macsec0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## MACsec options

**set interfaces macsec <interface> security cipher <gcm-aes-128|gcm-aes-256>**

Select cipher suite used for cryptographic operations. This setting is mandatory.

**set interfaces macsec <interface> security encrypt**

MACsec only provides authentication by default, encryption is optional. This command will enable encryption for all outgoing packets.

**set interfaces macsec <interface> source-interface <physical-source>**

A physical interface is required to connect this MACsec instance to. Traffic leaving this interface will now be authenticated/encrypted.

## Static Keys

Static SAK (Secure Authentication Key) mode can be configured manually on each device wishing to use MACsec. Keys must be set statically on all devices for traffic to flow properly. Key rotation is dependent on the administrator updating all keys manually across connected devices. Static SAK mode can not be used with MKA.

**set interfaces macsec <interface> security static key <key>**

Set the device's transmit (TX) key. This key must be a hex string that is 16-bytes (GCM-AES-128) or 32-bytes (GCM-AES-256).

**set interfaces macsec <interface> security static peer <peer> mac <mac address>**

Set the peer's MAC address

```
set interfaces macsec <interface> security static peer <peer> key <key>
```

Set the peer's key used to receive (RX) traffic

```
set interfaces macsec <interface> security static peer <peer> disable
```

Disable the peer configuration

## Key Management

MKA (MACsec Key Agreement protocol) is used to synchronize keys between individual peers.

```
set interfaces macsec <interface> security mka cak <key>
```

IEEE 802.1X/MACsec pre-shared key mode. This allows configuring MACsec with a pre-shared key using a CAK (MACsec connectivity association key) and CKN (MACsec connectivity association name) pair.

```
set interfaces macsec <interface> security mka ckn <key>
```

CKN key

```
set interfaces macsec <interface> security mka priority <priority>
```

The peer with lower priority will become the key server and start distributing SAKs.

## Replay protection

```
set interfaces macsec <interface> security replay-window <window>
```

IEEE 802.1X/MACsec replay protection window. This determines a window in which replay is tolerated, to allow receipt of frames that have been misordered by the network.

- 0: No replay window, strict check
- 1-4294967295: Number of packets that could be misordered

## Operation

```
run generate macsec mka cak <gcm-aes-128|gcm-aes-256>
```

Generate MKA CAK key 128 or 256 bits.

```
vyos@vyos:~$ generate macsec mka cak gcm-aes-128
20693b6e08bfa482703a563898c9e3ad
```

```
run generate macsec mka ckn
```

Generate MKA CAK key.

```
vyos@vyos:~$ generate macsec mka ckn
88737efef314ee319b2cbf30210a5f164957d884672c143aefdc0f5f6bc49eb2
```

```
show interfaces macsec
```

List all MACsec interfaces.

```
vyos@vyos:~$ show interfaces macsec
17: macsec1: protect on validate strict sc off sa off encrypt on send_sci on end_
↳station off scb off replay off
   cipher suite: GCM-AES-128, using ICV length 16
   TXSC: 005056bfefaa0001 on SA 0
20: macsec0: protect on validate strict sc off sa off encrypt off send_sci on end_
↳station off scb off replay off
   cipher suite: GCM-AES-128, using ICV length 16
   TXSC: 005056bfefaa0001 on SA 0
```

### show interfaces macsec <interface>

Show specific MACsec interface information

```
vyos@vyos:~$ show interfaces macsec macsec1
17: macsec1: protect on validate strict sc off sa off encrypt on send_sci on end_
↳station off scb off replay off
   cipher suite: GCM-AES-128, using ICV length 16
   TXSC: 005056bfefaa0001 on SA 0
```

## Examples

- Two routers connected both via eth1 through an untrusted switch
- R1 has 192.0.2.1/24 & 2001:db8::1/64
- R2 has 192.0.2.2/24 & 2001:db8::2/64

### R1

```
set interfaces macsec macsec1 address '192.0.2.1/24'
set interfaces macsec macsec1 address '2001:db8::1/64'
set interfaces macsec macsec1 security cipher 'gcm-aes-128'
set interfaces macsec macsec1 security encrypt
set interfaces macsec macsec1 security mka cak '232e44b7fda6f8e2d88a07bf78a7aff4'
set interfaces macsec macsec1 security mka ckn
↳'40916f4b23e3d548ad27eedd2d10c6f98c2d21684699647d63d41b500dfe8836'
set interfaces macsec macsec1 source-interface 'eth1'
```

### R2

```
set interfaces macsec macsec1 address '192.0.2.2/24'
set interfaces macsec macsec1 address '2001:db8::2/64'
set interfaces macsec macsec1 security cipher 'gcm-aes-128'
set interfaces macsec macsec1 security encrypt
set interfaces macsec macsec1 security mka cak '232e44b7fda6f8e2d88a07bf78a7aff4'
set interfaces macsec macsec1 security mka ckn
↳'40916f4b23e3d548ad27eedd2d10c6f98c2d21684699647d63d41b500dfe8836'
set interfaces macsec macsec1 source-interface 'eth1'
```

Pinging (IPv6) the other host and intercepting the traffic in eth1 will show you the content is encrypted.

```

set interfaces macsec macsec1 source-interface 'eth1'

```

### 8.4.9 OpenVPN

Traditionally hardware routers implement IPsec exclusively due to relative ease of implementing it in hardware and insufficient CPU power for doing encryption in software. Since VyOS is a software router, this is less of a concern. OpenVPN has been widely used on UNIX platform for a long time and is a popular option for remote access VPN, though it's also capable of site-to-site connections.

Advantages of OpenVPN are:

- It uses a single TCP or UDP connection and does not rely on packet source addresses, so it will work even through a double NAT: perfect for public hotspots and such
- It's easy to setup and offers very flexible split tunneling
- There's a variety of client GUI frontends for any platform

Disadvantages are:

- It's slower than IPsec due to higher protocol overhead and the fact it runs in user mode while IPsec, on Linux, is in kernel mode
- None of the operating systems have client software installed by default

In the VyOS CLI, a key point often overlooked is that rather than being configured using the `set vpn` stanza, OpenVPN is configured as a network interface using `set interfaces openvpn`.

#### Site-to-Site

OpenVPN is popular for client-server setups, but its site-to-site mode remains a relatively obscure feature, and many router appliances still don't support it. However, it's very useful for quickly setting up tunnels between routers.

As of VyOS 1.4, OpenVPN site-to-site mode can use either pre-shared keys or x.509 certificates.

The pre-shared key mode is deprecated and will be removed from future OpenVPN versions, so VyOS will have to remove support for that option as well. The reason is that using pre-shared keys is significantly less secure than using TLS.

We'll configure OpenVPN using self-signed certificates, and then discuss the legacy pre-shared key mode.

In both cases, we will use the following settings:

- The public IP address of the local side of the VPN will be 198.51.100.10.
- The public IP address of the remote side of the VPN will be 203.0.113.11.
- The tunnel will use 10.255.1.1 for the local IP and 10.255.1.2 for the remote.
- The local site will have a subnet of 10.0.0.0/16.
- The remote site will have a subnet of 10.1.0.0/16.
- The official port for OpenVPN is 1194, which we reserve for client VPN; we will use 1195 for site-to-site VPN.
- The `persistent-tunnel` directive will allow us to configure tunnel-related attributes, such as firewall policy as we would on any normal network interface.
- If known, the IP of the remote router can be configured using the `remote-host` directive; if unknown, it can be omitted. We will assume a dynamic IP for our remote router.

## Setting up certificates

Setting up a full-blown PKI with a CA certificate would arguably defeat the purpose of site-to-site OpenVPN, since its main goal is supposed to be configuration simplicity, compared to server setups that need to support multiple clients.

However, since VyOS 1.4, it is possible to verify self-signed certificates using certificate fingerprints.

On both sides, you need to generate a self-signed certificate, preferably using the „ec“ (elliptic curve) type. You can generate them by executing command `run generate pki certificate self-signed install <name>` in the configuration mode. Once the command is complete, it will add the certificate to the configuration session, to the `pki` subtree. You can then review the proposed changes and commit them.

```
vyos@vyos# run generate pki certificate self-signed install openvpn-local
Enter private key type: [rsa, dsa, ec] (Default: rsa) ec
Enter private key bits: (Default: 256)
Enter country code: (Default: GB)
Enter state: (Default: Some-State)
Enter locality: (Default: Some-City)
Enter organization name: (Default: VyOS)
Enter common name: (Default: vyos.io)
Do you want to configure Subject Alternative Names? [y/N]
Enter how many days certificate will be valid: (Default: 365)
Enter certificate type: (client, server) (Default: server)
Note: If you plan to use the generated key on this router, do not encrypt the private_
↵key.
Do you want to encrypt the private key with a passphrase? [y/N]
2 value(s) installed. Use "compare" to see the pending changes, and "commit" to apply.
[edit]

vyos@vyos# compare

+   }
+ }

[edit]

vyos@vyos# commit

```

You do **not** need to copy the certificate to the other router. Instead, you need to retrieve its SHA-256 fingerprint. OpenVPN only supports SHA-256 fingerprints at the moment, so you need to use the following command:

```

vyos@vyos# run show pki certificate openvpn-local fingerprint sha256
5C:B8:09:64:8B:59:51:DC:F4:DF:2C:12:5C:B7:03:D1:68:94:D7:5B:62:C2:E1:83:79:F1:F0:68:B2:81:26:79

```

Note: certificate names don't matter, we use ,openvpn-local' and ,openvpn-remote' but they can be arbitrary.

Repeat the procedure on the other router.

## Setting up OpenVPN

Local Configuration:

```

Configure the tunnel:

set interfaces openvpn vtun1 mode site-to-site
set interfaces openvpn vtun1 protocol udp
set interfaces openvpn vtun1 persistent-tunnel
set interfaces openvpn vtun1 remote-host '203.0.113.11' # Public_
→IP of the other side
set interfaces openvpn vtun1 local-port '1195'
set interfaces openvpn vtun1 remote-port '1195'
set interfaces openvpn vtun1 local-address '10.255.1.1' # Local_
→IP of vtun interface
set interfaces openvpn vtun1 remote-address '10.255.1.2' # Remote_
→IP of vtun interface
set interfaces openvpn vtun1 tls certificate 'openvpn-local' # The_
→self-signed certificate
set interfaces openvpn vtun1 tls peer-fingerprint <remote cert fingerprint> # The_
→output of 'run show pki certificate <name> fingerprint sha256'
on the_
→remote rout

```

Remote Configuration:

```

set interfaces openvpn vtun1 mode site-to-site
set interfaces openvpn vtun1 protocol udp
set interfaces openvpn vtun1 persistent-tunnel
set interfaces openvpn vtun1 remote-host '198.51.100.10'           # Pub
↪ IP of other site
set interfaces openvpn vtun1 local-port '1195'
set interfaces openvpn vtun1 remote-port '1195'
set interfaces openvpn vtun1 local-address '10.255.1.2'           # Local
↪ IP of vtun interface
set interfaces openvpn vtun1 remote-address '10.255.1.1'           #
↪ Remote IP of vtun interface
set interfaces openvpn vtun1 tls certificate 'openvpn-remote'       # The
↪ self-signed certificate
set interfaces openvpn vtun1 tls peer-fingerprint <local cert fingerprint> # The
↪ output of 'run show pki certificate <name> fingerprint sha256'
  on the
↪ local router

```

## Pre-shared keys

Until VyOS 1.4, the only option for site-to-site OpenVPN without PKI was to use pre-shared keys. That option is still available but it is deprecated and will be removed in the future. However, if you need to set up a tunnel to an older VyOS version or a system with older OpenVPN, you need to still need to know how to use it.

First, you need to generate a key by running `run generate pki openvpn shared-secret install <name>` from configuration mode. You can use any name, we will use `s2s`.

```

vyos@local# run generate pki openvpn shared-secret install s2s
2 value(s) installed. Use "compare" to see the pending changes, and "commit" to apply.
[edit]
vyos@local# compare
[pki openvpn shared-secret]
+ s2s {
+   key
↪ "7c73046a9da91e874d31c7ad894a32688cda054bde157c64270f28ecee0bb2f44dbb70335fad45148b0456aaa78cb34a34"
↪ "
+   version "1"
+ }

[edit]

vyos@local# commit
[edit]

```

Then you need to install the key on the remote router:

```
vyos@remote# set pki openvpn shared-secret s2s key <generated key string>
```

Then you need to set the key in your OpenVPN interface settings:

```
set interfaces openvpn vtun1 shared-secret-key s2s
```

## Firewall Exceptions

For the OpenVPN traffic to pass through the WAN interface, you must create a firewall exception.

```
set firewall name OUTSIDE_LOCAL rule 10 action accept
set firewall name OUTSIDE_LOCAL rule 10 description 'Allow established/related'
set firewall name OUTSIDE_LOCAL rule 10 state established enable
set firewall name OUTSIDE_LOCAL rule 10 state related enable
set firewall name OUTSIDE_LOCAL rule 20 action accept
set firewall name OUTSIDE_LOCAL rule 20 description OpenVPN_IN
set firewall name OUTSIDE_LOCAL rule 20 destination port 1195
set firewall name OUTSIDE_LOCAL rule 20 log enable
set firewall name OUTSIDE_LOCAL rule 20 protocol udp
set firewall name OUTSIDE_LOCAL rule 20 source
```

You should also ensure that the OUTSIDE\_LOCAL firewall group is applied to the WAN interface and a direction (local).

```
set firewall interface eth0 local name 'OUTSIDE-LOCAL'
```

### Static Routing:

Static routes can be configured referencing the tunnel interface; for example, the local router will use a network of 10.0.0.0/16, while the remote has a network of 10.1.0.0/16:

### Local Configuration:

```
set protocols static route 10.1.0.0/16 interface vtun1
```

### Remote Configuration:

```
set protocols static route 10.0.0.0/16 interface vtun1
```

The configurations above will default to using 256-bit AES in GCM mode for encryption (if both sides support NCP) and SHA-1 for HMAC authentication. SHA-1 is considered weak, but other hashing algorithms are available, as are encryption algorithms:

### For Encryption:

This sets the cipher when NCP (Negotiable Crypto Parameters) is disabled or OpenVPN version < 2.4.0.

```
vyos@vyos# set interfaces openvpn vtun1 encryption cipher
```

Possible completions:

|           |                                      |
|-----------|--------------------------------------|
| des       | DES algorithm                        |
| 3des      | DES algorithm with triple encryption |
| bf128     | Blowfish algorithm with 128-bit key  |
| bf256     | Blowfish algorithm with 256-bit key  |
| aes128    | AES algorithm with 128-bit key CBC   |
| aes128gcm | AES algorithm with 128-bit key GCM   |
| aes192    | AES algorithm with 192-bit key CBC   |
| aes192gcm | AES algorithm with 192-bit key GCM   |
| aes256    | AES algorithm with 256-bit key CBC   |
| aes256gcm | AES algorithm with 256-bit key GCM   |

This sets the accepted ciphers to use when version => 2.4.0 and NCP is enabled (which is the default). Default NCP cipher for versions >= 2.4.0 is aes256gcm. The first cipher in this list is what server pushes to clients.

```
vyos@vyos# set int open vtun0 encryption ncp-ciphers
Possible completions:
des          DES algorithm
3des         DES algorithm with triple encryption
aes128       AES algorithm with 128-bit key CBC
aes128gcm    AES algorithm with 128-bit key GCM
aes192       AES algorithm with 192-bit key CBC
aes192gcm    AES algorithm with 192-bit key GCM
aes256       AES algorithm with 256-bit key CBC
aes256gcm    AES algorithm with 256-bit key GCM
```

For Hashing:

```
vyos@vyos# set interfaces openvpn vtun1 hash
Possible completions:
md5          MD5 algorithm
sha1         SHA-1 algorithm
sha256       SHA-256 algorithm
sha512       SHA-512 algorithm
```

If you change the default encryption and hashing algorithms, be sure that the local and remote ends have matching configurations, otherwise the tunnel will not come up.

Firewall policy can also be applied to the tunnel interface for *local*, *in*, and *out* directions and functions identically to ethernet interfaces.

If making use of multiple tunnels, OpenVPN must have a way to distinguish between different tunnels aside from the pre-shared-key. This is either by referencing IP address or port number. One option is to dedicate a public IP to each tunnel. Another option is to dedicate a port number to each tunnel (e.g. 1195,1196,1197...).

OpenVPN status can be verified using the *show openvpn* operational commands. See the built-in help for a complete list of options.

## Server

Multi-client server is the most popular OpenVPN mode on routers. It always uses x.509 authentication and therefore requires a PKI setup. Refer this topic [PKI](#) to generate a CA certificate, a server certificate and key, a certificate revocation list, a Diffie-Hellman key exchange parameters file. You do not need client certificates and keys for the server setup.

In this example we will use the most complicated case: a setup where each client is a router that has its own subnet (think HQ and branch offices), since simpler setups are subsets of it.

Suppose you want to use 10.23.1.0/24 network for client tunnel endpoints and all client subnets belong to 10.23.0.0/20. All clients need access to the 192.168.0.0/16 network.

First we need to specify the basic settings. 1194/UDP is the default. The *persistent-tunnel* option is recommended, it prevents the TUN/TAP device from closing on connection resets or daemon reloads.

**Bemerkung:** Using *openvpn-option -reneg-sec* can be tricky. This option is used to renegotiate data channel after *n* seconds. When used at both server and client, the lower value will trigger the renegotiation. If you set it to 0 on one side of the connection (to disable it), the chosen value on the other side will determine when the renegotiation will occur.

```
set interfaces openvpn vtun10 mode server
set interfaces openvpn vtun10 local-port 1194
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set interfaces openvpn vtun10 persistent-tunnel
set interfaces openvpn vtun10 protocol udp
```

Then we need to generate, add and specify the names of the cryptographic materials. Each of the install command should be applied to the configuration and committed before using under the openvpn interface configuration.

```
run generate pki ca install ca-1 # Follow the
↳ instructions to generate CA cert.
Configure mode commands to install:
set pki ca ca-1 certificate 'generated_cert_string'
set pki ca ca-1 private key 'generated_private_key'

run generate pki certificate sign ca-1 install srv-1 # Follow the
↳ instructions to generate server cert.
Configure mode commands to install:
set pki certificate srv-1 certificate 'generated_server_cert'
set pki certificate srv-1 private key 'generated_private_key'

run generate pki dh install dh-1 # Follow the
↳ instructions to generate set of
Diffie-Hellman
↳ parameters.
Generating parameters...
Configure mode commands to install DH parameters:
set pki dh dh-1 parameters 'generated_dh_params_set'

set interfaces openvpn vtun10 tls ca-certificate ca-1
set interfaces openvpn vtun10 tls certificate srv-1
set interfaces openvpn vtun10 tls dh-params dh-1
```

Now we need to specify the server network settings. In all cases we need to specify the subnet for client tunnel endpoints. Since we want clients to access a specific network behind our router, we will use a push-route option for installing that route on clients.

```
set interfaces openvpn vtun10 server push-route 192.168.0.0/16
set interfaces openvpn vtun10 server subnet 10.23.1.0/24
```

Since it's a HQ and branch offices setup, we will want all clients to have fixed addresses and we will route traffic to specific subnets through them. We need configuration for each client to achieve this.

---

**Bemerkung:** Clients are identified by the CN field of their x.509 certificates, in this example the CN is `client0`:

---

```
set interfaces openvpn vtun10 server client client0 ip 10.23.1.10
set interfaces openvpn vtun10 server client client0 subnet 10.23.2.0/25
```

OpenVPN **will not** automatically create routes in the kernel for client subnets when they connect and will only use client-subnet association internally, so we need to create a route to the 10.23.0.0/20 network ourselves:

```
set protocols static route 10.23.0.0/20 interface vtun10
```

Additionally, each client needs a copy of ca cert and its own client key and cert files. The files are plaintext so they may be copied either manually from the CLI. Client key and cert files should be signed with the proper ca cert and generated

on the server side.

HQ's router requires the following steps to generate crypto materials for the Branch 1:

```
run generate pki certificate sign ca-1 install branch-1      # Follow the
↳ instructions to generate client                          cert for Branch 1

Configure mode commands to install:
```

Branch 1's router might have the following lines:

```
set pki ca ca-1 certificate 'generated_cert_string'        # CA cert generated
↳ on HQ router
set pki certificate branch-1 certificate 'generated_branch_cert' # Client cert
↳ generated and signed on HQ router
set pki certificate branch-1 private key 'generated_private_key' # Client cert key
↳ generated on HQ router

set interfaces openvpn vtun10 tls ca-cert ca-1
set interfaces openvpn vtun10 tls certificate branch-1
```

## Client Authentication

### LDAP

Enterprise installations usually ship a kind of directory service which is used to have a single password store for all employees. VyOS and OpenVPN support using LDAP/AD as single user backend.

Authentication is done by using the `openvpn-auth-ldap.so` plugin which is shipped with every VyOS installation. A dedicated configuration file is required. It is best practise to store it in `/config` to survive image updates

```
set interfaces openvpn vtun0 openvpn-option "--plugin /usr/lib/openvpn/openvpn-auth-ldap.
↳ so /config/auth/ldap-auth.config"
```

The required config file may look like this:

```
<LDAP>
# LDAP server URL
URL          ldap://ldap.example.com
# Bind DN (If your LDAP server doesn't support anonymous binds)
BindDN       cn=LDAPUser,dc=example,dc=com
# Bind Password password
Password     S3cr3t
# Network timeout (in seconds)
Timeout      15
</LDAP>

<Authorization>
# Base DN
BaseDN       "ou=people,dc=example,dc=com"
# User Search Filter
SearchFilter "(&(uid=%u)(objectClass=shadowAccount))"
# Require Group Membership - allow all users
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
RequireGroup    false
</Authorization>
```

## Active Directory

Despite the fact that AD is a superset of LDAP

```
<LDAP>
# LDAP server URL
URL ldap://dc01.example.com
# Bind DN (If your LDAP server doesn't support anonymous binds)
BindDN CN=LDAPUser,DC=example,DC=com
# Bind Password
Password mysecretpassword
# Network timeout (in seconds)
Timeout 15
# Enable Start TLS
TLSEnable no
# Follow LDAP Referrals (anonymously)
FollowReferrals no
</LDAP>

<Authorization>
# Base DN
BaseDN "DC=example,DC=com"
# User Search Filter, user must be a member of the VPN AD group
SearchFilter "(&(sAMAccountName=%u)(memberOf=CN=VPN,OU=Groups,DC=example,DC=com))"
# Require Group Membership
RequireGroup false # already handled by SearchFilter
<Group>
  BaseDN "OU=Groups,DC=example,DC=com"
  SearchFilter "(|(cn=VPN))"
  MemberAttribute memberOf
</Group>
</Authorization>
```

If you only want to check if the user account is enabled and can authenticate (against the primary group) the following snippet is sufficient:

```
<LDAP>
URL ldap://dc01.example.com
BindDN CN=SA_OPENVPN,OU=ServiceAccounts,DC=example,DC=com
Password ThisIsTopSecret
Timeout 15
TLSEnable no
FollowReferrals no
</LDAP>

<Authorization>
BaseDN "DC=example,DC=com"
SearchFilter "sAMAccountName=%u"
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

    RequireGroup    false
</Authorization>

```

A complete LDAP auth OpenVPN configuration could look like the following example:

```

vyos@vyos# show interfaces openvpn
openvpn vtun0 {
    mode server
    openvpn-option "--tun-mtu 1500 --fragment 1300 --mssfix"
    openvpn-option "--plugin /usr/lib/openvpn/openvpn-auth-ldap.so /config/auth/ldap-
    ↪auth.config"
    openvpn-option "--push redirect-gateway"
    openvpn-option --duplicate-cn
    openvpn-option "--verify-client-cert none"
    openvpn-option --comp-lzo
    openvpn-option --persist-key
    openvpn-option --persist-tun
    server {
        domain-name example.com
        max-connections 5
        name-server 203.0.113.0.10
        name-server 198.51.100.3
        subnet 172.18.100.128/29
    }
    tls {
        ca-certificate ca.crt
        certificate server.crt
        dh-params dh1024.pem
    }
}

```

## Client

VyOS can not only act as an OpenVPN site-to-site or server for multiple clients. You can indeed also configure any VyOS OpenVPN interface as an OpenVPN client connecting to a VyOS OpenVPN server or any other OpenVPN server.

Given the following example we have one VyOS router acting as OpenVPN server and another VyOS router acting as OpenVPN client. The server also pushes a static client IP address to the OpenVPN client. Remember, clients are identified using their CN attribute in the SSL certificate.

## Configuration

### Server Side

```

set interfaces openvpn vtun10 encryption cipher 'aes256'
set interfaces openvpn vtun10 hash 'sha512'
set interfaces openvpn vtun10 local-host '172.18.201.10'
set interfaces openvpn vtun10 local-port '1194'
set interfaces openvpn vtun10 mode 'server'

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set interfaces openvpn vtun10 persistent-tunnel
set interfaces openvpn vtun10 protocol 'udp'
set interfaces openvpn vtun10 server client client1 ip '10.10.0.10'
set interfaces openvpn vtun10 server domain-name 'vyos.net'
set interfaces openvpn vtun10 server max-connections '250'
set interfaces openvpn vtun10 server name-server '172.16.254.30'
set interfaces openvpn vtun10 server subnet '10.10.0.0/24'
set interfaces openvpn vtun10 server topology 'subnet'
set interfaces openvpn vtun10 tls ca-cert ca-1
set interfaces openvpn vtun10 tls certificate srv-1
set interfaces openvpn vtun10 tls crypt-key srv-1
set interfaces openvpn vtun10 tls dh-params dh-1
set interfaces openvpn vtun10 use-lzo-compression

```

## Client Side

```

set interfaces openvpn vtun10 encryption cipher 'aes256'
set interfaces openvpn vtun10 hash 'sha512'
set interfaces openvpn vtun10 mode 'client'
set interfaces openvpn vtun10 persistent-tunnel
set interfaces openvpn vtun10 protocol 'udp'
set interfaces openvpn vtun10 remote-host '172.18.201.10'
set interfaces openvpn vtun10 remote-port '1194'
set interfaces openvpn vtun10 tls ca-cert ca-1
set interfaces openvpn vtun10 tls certificate client-1
set interfaces openvpn vtun10 tls crypt-key client-1
set interfaces openvpn vtun10 use-lzo-compression

```

## Options

We do not have CLI nodes for every single OpenVPN option. If an option is missing, a feature request should be opened at [Phabricator](#) so all users can benefit from it (see [Issues/Feature requests](#)).

If you are a hacker or want to try on your own we support passing raw OpenVPN options to OpenVPN.

```
set interfaces openvpn vtun10 openvpn-option ,persistent-key'
```

Will add `persistent-key` at the end of the generated OpenVPN configuration. Please use this only as last resort - things might break and OpenVPN won't start if you pass invalid options/syntax.

```
set interfaces openvpn vtun10 openvpn-option ,push 'keepalive 1 10'
```

Will add `push "keepalive 1 10"` to the generated OpenVPN config file.

---

**Bemerkung:** Sometimes option lines in the generated OpenVPN configuration require quotes. This is done through a hack on our config generator. You can pass quotes using the `&quot;` statement.

---

## OpenVPN Data Channel Offload (DCO)

OpenVPN Data Channel Offload (DCO) enables significant performance enhancement in encrypted OpenVPN data processing. By minimizing context switching for each packet, DCO effectively reduces overhead. This optimization is achieved by keeping most data handling tasks within the kernel, avoiding frequent switches between kernel and user space for encryption and packet handling.

As a result, the processing of each packet becomes more efficient, potentially leveraging hardware encryption offloading support available in the kernel.

---

**Bemerkung:** OpenVPN DCO is not full OpenVPN features supported, is currently considered experimental. Furthermore, there are certain OpenVPN features and use cases that remain incompatible with DCO. To get a comprehensive understanding of the limitations associated with DCO, refer to the list of known limitations in the documentation.

<https://community.openvpn.net/openvpn/wiki/DataChannelOffload/Features>

---

## Enabling OpenVPN DCO

DCO support is a per-tunnel option and it is not automatically enabled by default for new or upgraded tunnels. Existing tunnels will continue to function as they have in the past.

DCO can be enabled for both new and existing tunnels, VyOS adds an option in each tunnel configuration where we can enable this function. The current best practice is to create a new tunnel with DCO to minimize the chance of problems with existing clients.

**set interfaces openvpn <name> offload dco**

Enable OpenVPN Data Channel Offload feature by loading the appropriate kernel module.

Disabled by default - no kernel module loaded.

---

**Bemerkung:** Enable this feature causes an interface reset.

---

## Troubleshooting

VyOS provides some operational commands on OpenVPN.

### Check status

The following commands let you check tunnel status.

**show openvpn client**

Use this command to check the tunnel status for OpenVPN client interfaces.

**show openvpn server**

Use this command to check the tunnel status for OpenVPN server interfaces.

**show openvpn site-to-site**

Use this command to check the tunnel status for OpenVPN site-to-site interfaces.

## Reset OpenVPN

The following commands let you reset OpenVPN.

**reset openvpn client <text>**

Use this command to reset the specified OpenVPN client.

**reset openvpn interface <interface>**

Use this command to reset the OpenVPN process on a specific interface.

## 8.4.10 WireGuard

WireGuard is an extremely simple yet fast and modern VPN that utilizes state-of-the-art cryptography. See <https://www.wireguard.com> for more information.

### Site to Site VPN

This diagram corresponds with the example site to site configuration below.

### Keypairs

WireGuard requires the generation of a keypair, which includes a private key to decrypt incoming traffic, and a public key for peer(s) to encrypt traffic.

## Generate Keypair

### generate pki wireguard key-pair

It generates the keypair, which includes the public and private parts. The key is not stored on the system - only a keypair is generated.

```
vyos@vyos:~$ generate pki wireguard key-pair
Private key: iJjyEARGK52Ls1GYRCcFvPuTj7WyWYDo//BknoDU0XY=
Public key: EKY0dxRrSD98QHj fHOK13mZ5PJ7hnddRZt5woB3szyw=
```

### generate pki wireguard key-pair install interface <interface>

Generates a keypair, which includes the public and private parts, and build a configuration command to install this key to interface.

```
vyos@vyos:~$ generate pki wireguard key-pair install interface wg10
"generate" CLI command executed from operational level.
Generated private-key is not stored to CLI, use configure mode commands to install.
→key:

set interfaces wireguard wg10 private-key
→ '4KrkV8h6NkAYMMaBWI957yYDJDMvj9URTHstdl0cDU0='

Corresponding public-key to use on peer system is:
→ 'UxDsYT6EnpTIOKUzvMlw2p0sNOKQvFxEsVrnNrX1Ro='
```

**Bemerkung:** If this command is invoked from configure mode with the run prefix the key is automatically installed to the appropriate interface:

```
vyos@vyos# run generate pki wireguard key-pair install interface wg10
"generate" CLI command executed from config session.
Generated private-key was imported to CLI!

Use the following command to verify: show interfaces wireguard wg10
Corresponding public-key to use on peer system is: '7d9KwabjLhHpJiEJeIGd0CBla0/
→eTwF0h6xyCovTfG8='

vyos@vyos# compare
[edit interfaces]
+wireguard wg10 {
+  private-key CJweb8FC6BU3Loj4PC2pn5V82cDjIPs7G1saW0ZfLWc=
+}
```

### show interfaces wireguard <interface> public-key

Retrieve public key portion from configured WIREGUARD interface.

```
vyos@vyos:~$ show interfaces wireguard wg01 public-key
EKY0dxRrSD98QHj fHOK13mZ5PJ7hnddRZt5woB3szyw=
```

## Optional

### generate pki wireguard preshared-key

An additional layer of symmetric-key crypto can be used on top of the asymmetric crypto.

This is optional.

```
vyos@vyos:~$ generate pki wireguard preshared-key
Pre-shared key: OHH2EwZfMNK+1L6BXbYw3bKCtMrfjpR4mCAEeBlFnRs=
```

### generate pki wireguard preshared-key install interface <interface> peer <peer>

An additional layer of symmetric-key crypto can be used on top of the asymmetric crypto. This command automatically creates for you the required CLI command to install this PSK for a given peer.

This is optional.

```
vyos@vyos:~$ generate pki wireguard preshared-key install interface wg10 peer foo
"generate" CLI command executed from operational level.
Generated preshared-key is not stored to CLI, use configure mode commands to
→ install key:

set interfaces wireguard wg10 peer foo preshared-key
→ '32vQ1w1yFKTna8n7Gu7EimubSe2Y63m8bafz55EG3Ro='

Pre-shared key: +LuaZ8W6DjsDFJFX3jJzoNqrsXHhvfq08JztM9z8LHCs=
```

---

**Bemerkung:** If this command is invoked from configure mode with the `run` prefix the key is automatically installed to the appropriate interface:

---

## Interface configuration

The next step is to configure your local side as well as the policy based trusted destination addresses. If you only initiate a connection, the listen port and address/port is optional; however, if you act like a server and endpoints initiate the connections to your system, you need to define a port your clients can connect to, otherwise the port is randomly chosen and may make connection difficult with firewall rules, since the port may be different each time the system is rebooted.

You will also need the public key of your peer as well as the network(s) you want to tunnel (allowed-ips) to configure a WireGuard tunnel. The public key below is always the public key from your peer, not your local one.

### local side - commands

- WireGuard interface itself uses address 10.1.0.1/30
- We only allow the 192.168.2.0/24 subnet to travel over the tunnel
- Our remote end of the tunnel for peer `to-wg02` is reachable at 192.0.2.1 port 51820
- The remote peer `to-wg02` uses `XMrlPykaxhdAAiSjhtPlvi30NVkvLQliQuKP7AI7CyI=` as its public key portion
- We listen on port 51820
- We route all traffic for the 192.168.2.0/24 network to interface `wg01`

```

set interfaces wireguard wg01 address '10.1.0.1/30'
set interfaces wireguard wg01 description 'VPN-to-wg02'
set interfaces wireguard wg01 peer to-wg02 allowed-ips '192.168.2.0/24'
set interfaces wireguard wg01 peer to-wg02 address '192.0.2.1'
set interfaces wireguard wg01 peer to-wg02 port '51820'
set interfaces wireguard wg01 peer to-wg02 public-key
↪ 'XMrlPykaxhdAAiSjhtPlvi30NVkvLQliQuKP7AI7CyI='
set interfaces wireguard wg01 port '51820'

set protocols static route 192.168.2.0/24 interface wg01

```

The last step is to define an interface route for 192.168.2.0/24 to get through the WireGuard interface *wg01*. Multiple IPs or networks can be defined and routed. The last check is allowed-ips which either prevents or allows the traffic.

**Warning:** You can not assign the same allowed-ips statement to multiple WireGuard peers. This a design decision. For more information please check the [WireGuard mailing list](#).

### **set interfaces wireguard <interface> private-key <private-key>**

Associates the previously generated private key to a specific WireGuard interface. The private key can be generate via the command

generate pki wireguard key-pair.

```

set interfaces wireguard wg01 private-key 'iJJyEARGK52Ls1GYRCcFvPuTj7WyWYDo//
↪ BknoDU0XY='

```

The command `show interfaces wireguard wg01 public-key` will then show the public key, which needs to be shared with the peer.

### **set interfaces wireguard <interface> per-client-thread**

Provides a per-device control to enable/disable the threaded mode for all the NAPI instances of the given network device, without the need for a device up/down.

If CLI option is not specified, this feature is disabled.

Example:

```

set interfaces wireguard wg01 per-client-thread

```

### **remote side - commands**

```

set interfaces wireguard wg01 address '10.1.0.2/30'
set interfaces wireguard wg01 description 'VPN-to-wg01'
set interfaces wireguard wg01 peer to-wg01 allowed-ips '192.168.1.0/24'
set interfaces wireguard wg01 peer to-wg01 address '192.0.2.2'
set interfaces wireguard wg01 peer to-wg01 port '51820'
set interfaces wireguard wg01 peer to-wg01 public-key
↪ 'EKY0dxRrSD98QHjfhOK13mZ5PJ7hnddRZt5woB3szyw='
set interfaces wireguard wg01 port '51820'
set interfaces wireguard wg01 private-key 'OLTQY3HuK5qWDgVs6fJR093SwPgOmCKkDI1+vJLGoFU='

set protocols static route 192.168.1.0/24 interface wg01

```

## Firewall Exceptions

For the WireGuard traffic to pass through the WAN interface, you must create a firewall exception.

```
set firewall ipv4 name OUTSIDE_LOCAL rule 10 action accept
set firewall ipv4 name OUTSIDE_LOCAL rule 10 description 'Allow established/related'
set firewall ipv4 name OUTSIDE_LOCAL rule 10 state established enable
set firewall ipv4 name OUTSIDE_LOCAL rule 10 state related enable
set firewall ipv4 name OUTSIDE_LOCAL rule 20 action accept
set firewall ipv4 name OUTSIDE_LOCAL rule 20 description WireGuard_IN
set firewall ipv4 name OUTSIDE_LOCAL rule 20 destination port 51820
set firewall ipv4 name OUTSIDE_LOCAL rule 20 log enable
set firewall ipv4 name OUTSIDE_LOCAL rule 20 protocol udp
set firewall ipv4 name OUTSIDE_LOCAL rule 20 source
```

You should also ensure that the OUTSIDE\_LOCAL firewall group is applied to the WAN interface and a direction (local).

```
set interfaces ethernet eth0 firewall local name 'OUTSIDE-LOCAL'
```

Assure that your firewall rules allow the traffic, in which case you have a working VPN using WireGuard.

```
wg01# ping 192.168.1.1
PING 192.168.1.1 (192.168.1.1) 56(84) bytes of data.
64 bytes from 192.168.1.1: icmp_seq=1 ttl=64 time=1.16 ms
64 bytes from 192.168.1.1: icmp_seq=2 ttl=64 time=1.77 ms

wg02# ping 192.168.2.1
PING 192.168.2.1 (192.168.2.1) 56(84) bytes of data.
64 bytes from 192.168.2.1: icmp_seq=1 ttl=64 time=4.40 ms
64 bytes from 192.168.2.1: icmp_seq=2 ttl=64 time=1.02 ms
```

An additional layer of symmetric-key crypto can be used on top of the asymmetric crypto. This is optional.

```
vyos@vyos:~$ generate pki wireguard preshared-key
Pre-shared key: rvVD0oc2IYEnV+k5p7TNAmHBMEGTHbPU8Qqg8c/sUqc=
```

Copy the key, as it is not stored on the local filesystem. Because it is a symmetric key, only you and your peer should have knowledge of its content. Make sure you distribute the key in a safe manner,

```
wg01# set interfaces wireguard wg01 peer to-wg02 preshared-key
→ 'rvVD0oc2IYEnV+k5p7TNAmHBMEGTHbPU8Qqg8c/sUqc='
wg02# set interfaces wireguard wg01 peer to-wg01 preshared-key
→ 'rvVD0oc2IYEnV+k5p7TNAmHBMEGTHbPU8Qqg8c/sUqc='
```

## Remote Access „RoadWarrior“ Example

With WireGuard, a Road Warrior VPN config is similar to a site-to-site VPN. It just lacks the address and port statements.

In the following example, the IPs for the remote clients are defined in the peers. This allows the peers to interact with one another. In comparison to the site-to-site example the `persistent-keepalive` flag is set to 15 seconds to assure the connection is kept alive. This is mainly relevant if one of the peers is behind NAT and can't be connected to if the connection is lost. To be effective this value needs to be lower than the UDP timeout.

```
wireguard wg01 {
  address 10.172.24.1/24
  address 2001:db8:470:22::1/64
  description RoadWarrior
  peer MacBook {
    allowed-ips 10.172.24.30/32
    allowed-ips 2001:db8:470:22::30/128
    persistent-keepalive 15
    pubkey F5MbW7ye7Dsoxd0aixjdrudshjxxN5UdNV+pGFHqehc=
  }
  peer iPhone {
    allowed-ips 10.172.24.20/32
    allowed-ips 2001:db8:470:22::20/128
    persistent-keepalive 15
    pubkey BknHcLFo8n0o8Dwq2CjaC/TedchKQ0ebx7GYn7Al00=
  }
  port 2224
  private-key OLTQY3HuK5qWDgVs6fJR093SwPgOmCKkDI1+vJLGoFU=
}
```

The following is the config for the iPhone peer above. It's important to note that the `AllowedIPs` wildcard setting directs all IPv4 and IPv6 traffic through the connection.

```
[Interface]
PrivateKey = ARAKLSDJsadlkfjasdfiowqeruriowqeusdf=
Address = 10.172.24.20/24, 2001:db8:470:22::20/64
DNS = 10.0.0.53, 10.0.0.54

[Peer]
PublicKey = RIbtUTCfgzNjnLNPQ/ulkGnnB2vMWHm7l2H/xUfbyjc=
AllowedIPs = 0.0.0.0/0, ::/0
Endpoint = 192.0.2.1:2224
PersistentKeepalive = 25
```

However, split-tunneling can be achieved by specifying the remote subnets. This ensures that only traffic destined for the remote site is sent over the tunnel. All other traffic is unaffected.

```
[Interface]
PrivateKey = 8Iasdfweirousd1EVGUk5XsT+wYFZ9mhPnQhmjzaJE6Go=
Address = 10.172.24.30/24, 2001:db8:470:22::30/64

[Peer]
PublicKey = RIbtUTCfgzNjnLNPQ/ulkGnnB2vMWHm7l2H/xUfbyjc=
AllowedIPs = 10.172.24.30/24, 2001:db8:470:22::/64
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
Endpoint = 192.0.2.1:2224
PersistentKeepalive = 25
```

## Operational Commands

### Status

#### **show interfaces wireguard wg01 summary**

Show info about the Wireguard service. It also shows the latest handshake.

```
vyos@vyos:~$ show interfaces wireguard wg01 summary
interface: wg01
  public key:
  private key: (hidden)
  listening port: 51820

peer: <peer pubkey>
  endpoint: <peer public IP>
  allowed ips: 10.69.69.2/32
  latest handshake: 23 hours, 45 minutes, 26 seconds ago
  transfer: 1.26 MiB received, 6.47 MiB sent
```

#### **show interfaces wireguard**

Get a list of all wireguard interfaces

```
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
wg01           10.0.0.1/24     u/u
```

#### **show interfaces wireguard <interface>**

Show general information about specific WireGuard interface

```
vyos@vyos:~$ show interfaces wireguard wg01
interface: wg01
  address: 10.0.0.1/24
  public key: h1HkYlSuHdJN6Qv4Hz4bBzjGg5WUty+U1L7DJsZy1iE=
  private key: (hidden)
  listening port: 41751

  RX:  bytes  packets  errors  dropped  overrun  mcast
      0       0         0        0         0         0
  TX:  bytes  packets  errors  dropped  carrier  collisions
      0       0         0        0         0         0
```

## Remote Access „RoadWarrior“ clients

Some users tend to connect their mobile devices using WireGuard to their VyOS router. To ease deployment one can generate a „per mobile“ configuration from the VyOS CLI.

**Warnung:** From a security perspective, it is not recommended to let a third party create and share the private key for a secured connection. You should create the private portion on your own and only hand out the public key. Please keep this in mind when using this convenience feature.

**generate wireguard client-config** <name> **interface** <interface> **server** <ip|fqdn> **address** <client-ip>

Using this command, you will create a new client configuration which can connect to **interface** on this router. The public key from the specified interface is automatically extracted and embedded into the configuration.

The command also generates a configuration snippet which can be copy/pasted into the VyOS CLI if needed. The supplied <name> on the CLI will become the peer name in the snippet.

In addition you will specify the IP address or FQDN for the client where it will connect to. The address parameter can be used up to two times and is used to assign the clients specific IPv4 (/32) or IPv6 (/128) address.

### 8.4.11 PPPoE

PPPoE (Point-to-Point Protocol over Ethernet) is a network protocol for encapsulating PPP frames inside Ethernet frames. It appeared in 1999, in the context of the boom of DSL as the solution for tunneling packets over the DSL connection to the ISPs (Internet Service Providers) IP network, and from there to the rest of the Internet. A 2005 networking book noted that „Most DSL providers use PPPoE, which provides authentication, encryption, and compression.“ Typical use of PPPoE involves leveraging the PPP facilities for authenticating the user with a username and password, predominately via the PAP protocol and less often via CHAP.

## Operating Modes

VyOS supports setting up PPPoE in two different ways to a PPPoE internet connection. This is because most ISPs provide a modem that is also a wireless router.

## Home Users

In this method, the DSL Modem/Router connects to the ISP for you with your credentials preprogrammed into the device. This gives you an **RFC 1918** address, such as 192.168.1.0/24 by default.

For a simple home network using just the ISP's equipment, this is usually desirable. But if you want to run VyOS as your firewall and router, this will result in having a double NAT and firewall setup. This results in a few extra layers of complexity, particularly if you use some NAT or tunnel features.

WireGuard client configuration for interface: wg0

To enable this configuration on a VyOS router you can use the following commands:

=== VyOS (server) configuration ===

```
set interfaces wireguard wg0 peer foo allowed-ips '10.0.1.10/32'  
set interfaces wireguard wg0 peer foo allowed-ips '2001:db8::10/128'  
set interfaces wireguard wg0 peer foo pubkey 'Hk62WnBsZawKaBnucwmI8ZHZs6ABnr5M8OAC6vch/F4='
```

=== RoadWarrior (client) configuration ===

[Interface]

PrivateKey = kLlYfiTO+VrF8rzoBIsl9DrylDniwJUQie5jwWIXLFs=

Address = 10.0.1.10/32, 2001:db8::10/128

DNS = 1.1.1.1

[Peer]

PublicKey = h1HkYlSuHdJN6Qv4Hz4bBzjGg5WUty+U1L7DJs2yliE=

Endpoint = wireguard.vyos.net:41751

AllowedIPs = 0.0.0.0/0, ::/0

## Business Users

In order to have full control and make use of multiple static public IP addresses, your VyOS will have to initiate the PPPoE connection and control it. In order for this method to work, you will have to figure out how to make your DSL Modem/Router switch into a Bridged Mode so it only acts as a DSL Transceiver device to connect between the Ethernet link of your VyOS and the phone cable. Once your DSL Transceiver is in Bridge Mode, you should get no IP address from it. Please make sure you connect to the Ethernet Port 1 if your DSL Transceiver has a switch, as some of them only work this way.

Once you have an Ethernet device connected, i.e. *eth0*, then you can configure it to open the PPPoE session for you and your DSL Transceiver (Modem/Router) just acts to translate your messages in a way that vDSL/aDSL understands.

## Configuration

### Common interface configuration

**set interfaces pppoe <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces pppoe pppoe0 description 'This is an awesome interface running on
↳ VyOS'
```

**set interfaces pppoe <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces pppoe pppoe0 disable
```

**set interfaces pppoe <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces pppoe pppoe0 mtu 1600
```

**set interfaces pppoe <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces pppoe pppoe0 vrf red
```

## PPPoE options

**set interfaces pppoe <interface> access-concentrator <name>**

Use this command to restrict the PPPoE session on a given access concentrator. Normally, a host sends a PPPoE initiation packet to start the PPPoE discovery process, a number of access concentrators respond with offer packets and the host selects one of the responding access concentrators to serve this session.

This command allows you to select a specific access concentrator when you know the access concentrators <name>.

**set interfaces pppoe <interface> authentication username <username>**

Use this command to set the username for authenticating with a remote PPPoE endpoint. Authentication is optional from the system's point of view but most service providers require it.

**set interfaces pppoe <interface> authentication password <password>**

Use this command to set the password for authenticating with a remote PPPoE endpoint. Authentication is optional from the system's point of view but most service providers require it.

**set interfaces pppoe <interface> connect-on-demand**

When set the interface is enabled for „dial-on-demand“.

Use this command to instruct the system to establish a PPPoE connection automatically once traffic passes through the interface. A disabled on-demand connection is established at boot time and remains up. If the link fails for any reason, the link is brought back up immediately.

Enabled on-demand PPPoE connections bring up the link only when traffic needs to pass this link. If the link fails for any reason, the link is brought back up automatically once traffic passes the interface again. If you configure an on-demand PPPoE connection, you must also configure the idle timeout period, after which an idle PPPoE link will be disconnected. A non-zero idle timeout will never disconnect the link after it first came up.

**set interfaces pppoe <interface> no-default-route**

Only request an address from the PPPoE server but do not install any default route.

Example:

```
set interfaces pppoe pppoe0 no-default-route
```

**Bemerkung:** This command got added in VyOS 1.4 and inverts the logic from the old `default-route` CLI option.

**set interfaces pppoe <interface> default-route-distance <distance>**

Set the distance for the default gateway sent by the PPPoE server.

Example:

```
set interfaces pppoe pppoe0 default-route-distance 220
```

**set interfaces pppoe <interface> mru <mru>**

Set the MRU (Maximum Receive Unit) to *mru*. PPPd will ask the peer to send packets of no more than *mru* bytes. The value of *mru* must be between 128 and 16384.

A value of 296 works well on very slow links (40 bytes for TCP/IP header + 256 bytes of data).

The default is 1492.

---

**Bemerkung:** When using the IPv6 protocol, MRU must be at least 1280 bytes.

---

**set interfaces pppoe <interface> idle-timeout <time>**

Use this command to set the idle timeout interval to be used with on-demand PPPoE sessions. When an on-demand connection is established, the link is brought up only when traffic is sent and is disabled when the link is idle for the interval specified.

If this parameter is not set or 0, an on-demand link will not be taken down when it is idle and after the initial establishment of the connection. It will stay up forever.

**set interfaces pppoe <interface> holdoff <time>**

Use this command to set re-dial delay time to be used with persist PPPoE sessions. When the PPPoE session is terminated by peer, and on-demand option is not set, the router will attempt to re-establish the PPPoE link.

If this parameter is not set, the default holdoff time is 30 seconds.

**set interfaces pppoe <interface> local-address <address>**

Use this command to set the IP address of the local endpoint of a PPPoE session. If it is not set it will be negotiated.

**set interfaces pppoe <interface> no-peer-dns**

Use this command to not install advertised DNS nameservers into the local system.

**set interfaces pppoe <interface> remote-address <address>**

Use this command to set the IP address of the remote endpoint of a PPPoE session. If it is not set it will be negotiated.

**set interfaces pppoe <interface> service-name <name>**

Use this command to specify a service name by which the local PPPoE interface can select access concentrators to connect with. It will connect to any access concentrator if not set.

**set interfaces pppoe <interface> source-interface <source-interface>**

Use this command to link the PPPoE connection to a physical interface. Each PPPoE connection must be established over a physical interface. Interfaces can be regular Ethernet interfaces, VIFs or bonding interfaces/VIFs.

**set interfaces pppoe <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally ,do not try to send me packets bigger than this value‘.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces pppoe <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

**set interfaces pppoe <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

## IPv6

**set interfaces pppoe <interface> ipv6 address autoconf**

Use this command to enable acquisition of IPv6 address using stateless autoconfig (SLAAC).

**set interfaces pppoe <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces pppoe <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

## DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

**set interfaces pppoe <interface> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces pppoe pppoe0 dhcpv6-options pd 0 length 56
```

**set interfaces pppoe <interface> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces pppoe pppoe0 dhcpv6-options pd 0 interface eth8 address 65534
```

**set interfaces pppoe <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces pppoe pppoe0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## Operation

**show interfaces pppoe <interface>**

Show detailed information on given <interface>

```
vyos@vyos:~$ show interfaces pppoe pppoe0
pppoe0: <POINTOPOINT,MULTICAST,NOARP,UP,LOWER_UP> mtu 1492 qdisc pfifo_fast state_
↪UNKNOWN group default qlen 3
  link/ppp
  inet 192.0.2.1 peer 192.0.2.255/32 scope global pppoe0
    valid_lft forever preferred_lft forever

  RX:  bytes    packets   errors   dropped   overrun    mcast
      7002658233   5064967         0         0         0         0
  TX:  bytes    packets   errors   dropped   carrier collisions
      533822843   1620173         0         0         0         0
```

**show interfaces pppoe <interface> queue**

Displays queue information for a PPPoE interface.

```
vyos@vyos:~$ show interfaces pppoe pppoe0 queue
qdisc pfifo_fast 0: root refcnt 2 bands 3 priomap  1 2 2 2 1 2 0 0 1 1 1 1 1 1 1 1
Sent 534625359 bytes 1626761 pkt (dropped 62, overlimits 0 requeues 0)
backlog 0b 0p requeues 0
```

## Connect/Disconnect

### disconnect interface <interface>

Test disconnecting given connection-oriented interface. <interface> can be pppoe0 as the example.

### connect interface <interface>

Test connecting given connection-oriented interface. <interface> can be pppoe0 as the example.

## Example

Requirements:

- Your ISP's modem is connected to port eth0 of your VyOS box.
- No VLAN tagging required by your ISP.
- You need your PPPoE credentials from your DSL ISP in order to configure this. The usual username is in the form of `name@host.net` but may vary depending on ISP.
- The largest MTU size you can use with DSL is 1492 due to PPPoE overhead. If you are switching from a DHCP based ISP like cable then be aware that things like VPN links may need to have their MTU sizes adjusted to work within this limit.
- With the `name-server` option set to `none`, VyOS will ignore the nameservers your ISP sends you and thus you can fully rely on the ones you have configured statically.

---

**Bemerkung:** Syntax has changed from VyOS 1.2 (crux) and it will be automatically migrated during an upgrade.

---

---

**Bemerkung:** A default route is automatically installed once the interface is up. To change this behavior use the `no-default-route` CLI option.

---

```
set interfaces pppoe pppoe0 authentication username 'userid'
set interfaces pppoe pppoe0 authentication password 'secret'
set interfaces pppoe pppoe0 source-interface 'eth0'
```

You should add a firewall to your configuration above as well by assigning it to the pppoe0 itself as shown here:

```
set firewall interface pppoe0 in name NET-IN
set firewall interface pppoe0 local name NET-LOCAL
set firewall interface pppoe0 out name NET-OUT
```

## VLAN Example

Some recent ISPs require you to build the PPPoE connection through a VLAN interface. One of those ISPs is e.g. Deutsche Telekom in Germany. VyOS can easily create a PPPoE session through an encapsulated VLAN interface. The following configuration will run your PPPoE connection through VLAN7 which is the default VLAN for Deutsche Telekom:

```
set interfaces pppoe pppoe0 authentication username 'userid'
set interfaces pppoe pppoe0 authentication password 'secret'
set interfaces pppoe pppoe0 source-interface 'eth0.7'
```

## IPv6 DHCPv6-PD Example

The following configuration will setup a PPPoE session source from eth1 and assign a /64 prefix out of a /56 delegation (requested from the ISP) to eth0. The IPv6 address assigned to eth0 will be <prefix>::1/64. If you do not know the prefix size delegated to you, start with sla-len 0.

In addition we setup IPv6 RA (Router Advertisements) to make the prefix known on the eth0 link.

```
set interfaces pppoe pppoe0 authentication username vyos
set interfaces pppoe pppoe0 authentication password vyos
set interfaces pppoe pppoe0 dhcpv6-options pd 0 interface eth0 address '1'
set interfaces pppoe pppoe0 dhcpv6-options pd 0 interface eth0 sla-id '0'
set interfaces pppoe pppoe0 dhcpv6-options pd 0 length '56'
set interfaces pppoe pppoe0 ipv6 address autoconf
set interfaces pppoe pppoe0 source-interface eth1

set service router-advert interface eth0 prefix ::/64
```

### 8.4.12 MACVLAN - Pseudo Ethernet

Pseudo-Ethernet or MACVLAN interfaces can be seen as subinterfaces to regular ethernet interfaces. Each and every subinterface is created a different media access control (MAC) address, for a single physical Ethernet port. Pseudo-Ethernet interfaces have most of their application in virtualized environments,

By using Pseudo-Ethernet interfaces there will be less system overhead compared to running a traditional bridging approach. Pseudo-Ethernet interfaces can also be used to workaround the general limit of 4096 virtual LANs (VLANs) per physical Ethernet port, since that limit is with respect to a single MAC address.

Every Virtual Ethernet interfaces behaves like a real Ethernet interface. They can have IPv4/IPv6 addresses configured, or can request addresses by DHCP/ DHCPv6 and are associated/mapped with a real ethernet port. This also makes Pseudo-Ethernet interfaces interesting for testing purposes. A Pseudo-Ethernet device will inherit characteristics (speed, duplex, ...) from its physical parent (the so called link) interface.

Once created in the system, Pseudo-Ethernet interfaces can be referenced in the exact same way as other Ethernet interfaces. Notes about using Pseudo- Ethernet interfaces:

- Pseudo-Ethernet interfaces can not be reached from your internal host. This means that you can not try to ping a Pseudo-Ethernet interface from the host system on which it is defined. The ping will be lost.
- Loopbacks occurs at the IP level the same way as for other interfaces, ethernet frames are not forwarded between Pseudo-Ethernet interfaces.
- Pseudo-Ethernet interfaces may not work in environments which expect a NIC (Network Interface Card) to only have a single address. This applies to: - VMware machines using default settings - Network switches with security settings allowing only a single MAC address - xDSL modems that try to learn the MAC address of the NIC

## Configuration

### Common interface configuration

**set interfaces pseudo-ethernet <interface> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
  - /config/scripts/dhcp-client/post-hooks.d/
- 

Example:

```
set interfaces pseudo-ethernet peth0 address 192.0.2.1/24
set interfaces pseudo-ethernet peth0 address 2001:db8::1/64
set interfaces pseudo-ethernet peth0 address dhcp
set interfaces pseudo-ethernet peth0 address dhcpv6
```

**set interfaces pseudo-ethernet <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces pseudo-ethernet peth0 description 'This is an awesome interface,
↳ running on VyOS'
```

**set interfaces pseudo-ethernet <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces pseudo-ethernet peth0 disable
```

**set interfaces pseudo-ethernet <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces pseudo-ethernet peth0 disable-flow-control
```

### **set interfaces pseudo-ethernet <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces pseudo-ethernet peth0 disable-link-detect
```

### **set interfaces pseudo-ethernet <interface> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces pseudo-ethernet peth0 mac '00:01:02:03:04:05'
```

### **set interfaces pseudo-ethernet <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces pseudo-ethernet peth0 mtu 1600
```

### **set interfaces pseudo-ethernet <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

### **set interfaces pseudo-ethernet <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces pseudo-ethernet peth0 ip arp-cache-timeout 180
```

### **set interfaces pseudo-ethernet <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned

by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces pseudo-ethernet peth0 ip disable-arp-filter
```

#### **set interfaces pseudo-ethernet <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces pseudo-ethernet peth0 ip disable-forwarding
```

#### **set interfaces pseudo-ethernet <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces pseudo-ethernet peth0 ip enable-directed-broadcast
```

#### **set interfaces pseudo-ethernet <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces pseudo-ethernet peth0 ip enable-arp-accept
```

#### **set interfaces pseudo-ethernet <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces pseudo-ethernet peth0 ip enable-arp-announce
```

#### **set interfaces pseudo-ethernet <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces pseudo-ethernet peth0 ip enable-arp-ignore
```

### **set interfaces pseudo-ethernet <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces pseudo-ethernet peth0 ip enable-proxy-arp
```

### **set interfaces pseudo-ethernet <interface> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

### **set interfaces pseudo-ethernet <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

### **set interfaces pseudo-ethernet <interface> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 address autoconf
```

**set interfaces pseudo-ethernet <interface> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces pseudo-ethernet <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 address no-default-link-local
```

**set interfaces pseudo-ethernet <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 disable-forwarding
```

**set interfaces pseudo-ethernet <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces pseudo-ethernet <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 accept-dad 2
```

**set interfaces pseudo-ethernet <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 dup-addr-detect-transmits 5
```

**set interfaces pseudo-ethernet <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces pseudo-ethernet peth0 vrf red
```

## DHCP(v6)

**set interfaces pseudo-ethernet <interface> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ‚client identifier‘ option. If the client supplies a ‚client identifier‘, the client MUST use the same ‚client identifier‘ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options client-id 'foo-bar'
```

**set interfaces pseudo-ethernet <interface> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options host-name 'VyOS'
```

**set interfaces pseudo-ethernet <interface> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces pseudo-ethernet <interface> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options no-default-route
```

**set interfaces pseudo-ethernet <interface> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options default-route-distance 220
```

**set interfaces pseudo-ethernet <interface> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options reject 192.168.100.0/24
```

**set interfaces pseudo-ethernet <interface> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options user-class VyOS
```

**set interfaces pseudo-ethernet <interface> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces pseudo-ethernet peth0 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

**set interfaces pseudo-ethernet <interface> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options no-release
```

**set interfaces pseudo-ethernet <interface> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options parameters-only
```

**set interfaces pseudo-ethernet <interface> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options rapid-commit
```

**set interfaces pseudo-ethernet <interface> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options temporary
```

### DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

**set interfaces pseudo-ethernet <interface> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces pseudo-ethernet peth0 dhcpv6-options pd 0 length 56
```

**set interfaces pseudo-ethernet <interface> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options pd 0 interface eth8 address_
→65534
```

**set interfaces pseudo-ethernet <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## Pseudo Ethernet/MACVLAN options

**set interfaces pseudo-ethernet <interface> source-interface <ethX>**

Specifies the physical <ethX> Ethernet interface associated with a Pseudo Ethernet <interface>.

## VLAN

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

**set interfaces pseudo-ethernet <interface> vif <vlan-id>**

Create a new VLAN interface on interface <interface> using the VLAN number provided via <vlan-id>.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

---

**Bemerkung:** Only 802.1Q-tagged packets are accepted on Ethernet vifs.

---

**set interfaces pseudo-ethernet <interface> vif <vlan-id> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
  - /config/scripts/dhcp-client/post-hooks.d/
- 

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 address 192.0.2.1/24
set interfaces pseudo-ethernet peth0 vif 10 address 2001:db8::1/64
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set interfaces pseudo-ethernet peth0 vif 10 address dhcp
set interfaces pseudo-ethernet peth0 vif 10 address dhcpv6
```

### **set interfaces pseudo-ethernet <interface> vif <vlan-id> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 description 'This is an awesome_
↳ interface running on VyOS'
```

### **set interfaces pseudo-ethernet <interface> vif <vlan-id> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 disable
```

### **set interfaces pseudo-ethernet <interface> vif <vlan-id> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 disable-link-detect
```

### **set interfaces pseudo-ethernet <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 mac '00:01:02:03:04:05'
```

### **set interfaces pseudo-ethernet <interface> vif <vlan-id> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 mtu 1600
```

### **set interfaces pseudo-ethernet <interface> vif <vlan-id> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally ,do not try to send me packets bigger than this value‘.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ip arp-cache-timeout 180
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ip disable-arp-filter
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces pseudo-ethernet peth0 vif 10 ip disable-forwarding
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces pseudo-ethernet peth0 vif 10 ip enable-directed-broadcast
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces pseudo-ethernet peth0 vif 10 ip enable-arp-accept
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces pseudo-ethernet peth0 vif 10 ip enable-arp-announce
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces pseudo-ethernet peth0 vif 10 ip enable-arp-ignore
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ip enable-proxy-arp
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 address autoconf
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 address no-default-link-local
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 disable-forwarding
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 accept-dad 2
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 dup-addr-detect-transmits 5
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 vrf red
```

## DHCP(v6)

**set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier' option. If the client supplies a ,client identifier', the client MUST use the same ,client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options client-id 'foo-bar'
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options host-name 'VyOS'
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options no-default-route
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options default-route-distance 220
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options reject 192.168.100.0/24
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options user-class VyOS
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its

type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces pseudo-ethernet peth0 vif 10 duid
↪ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

#### **set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options no-release
```

#### **set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options parameters-only
```

#### **set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options rapid-commit
```

#### **set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options temporary
```

### **DHCPv6 Prefix Delegation (PD)**

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

#### **set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options pd 0 length 56
```

#### **set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options pd 0 interface eth8
→address 65534
```

**set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options pd 0 interface eth8 sla-
→id 1
```

### 8.4.13 SSTP Client

SSTP (Secure Socket Tunneling Protocol) is a form of VTP (Virtual Private Network) tunnel that provides a mechanism to transport PPP traffic through an SSL/TLS channel. SSL/TLS provides transport-level security with key negotiation, encryption and traffic integrity checking. The use of SSL/TLS over TCP port 443 (by default, port can be changed) allows SSTP to pass through virtually all firewalls and proxy servers except for authenticated web proxies.

---

**Bemerkung:** VyOS also comes with a build in SSTP server, see [SSTP Server](#).

---

## Configuration

### Common interface configuration

**set interfaces sstpc <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces sstpc sstpc0 description 'This is an awesome interface running on
→VyOS'
```

**set interfaces sstpc <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces sstpc sstpc0 disable
```

**set interfaces sstpc <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces sstpc sstpc0 mtu 1600
```

**set interfaces sstpc <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces sstpc sstpc0 vrf red
```

## SSTP Client Options

**set interfaces sstpc <interface> no-default-route**

Only request an address from the SSTP server but do not install any default route.

Example:

```
set interfaces sstpc sstpc0 no-default-route
```

---

**Bemerkung:** This command got added in VyOS 1.4 and inverts the logic from the old `default-route` CLI option.

---

**set interfaces sstpc <interface> default-route-distance <distance>**

Set the distance for the default gateway sent by the SSTP server.

Example:

```
set interfaces sstpc sstpc0 default-route-distance 220
```

**set interfaces sstpc <interface> no-peer-dns**

Use this command to not install advertised DNS nameservers into the local system.

**set interfaces sstpc <interface> server <address>**

SSTP remote server to connect to. Can be either an IP address or FQDN.

**set interfaces sstpc <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value `clamp-mss-to-pmtu` can be used to automatically set the proper value.

**set interfaces sstpc <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

**set interfaces sstpc <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**Operation****show interfaces sstpc <interface>**

Show detailed information on given <interface>

```
vyos@vyos:~$ show interfaces sstpc sstpc10
sstpc10: <POINTOPOINT,MULTICAST,NOARP,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state_
↪UNKNOWN group default qlen 3
    link/ppp
    inet 192.0.2.5 peer 192.0.2.254/32 scope global sstpc10
        valid_lft forever preferred_lft forever
    inet6 fe80::fd53:c7ff:fe8b:144f/64 scope link
        valid_lft forever preferred_lft forever

RX:  bytes  packets  errors  dropped  overrun        mcast
     215      9        0        0         0           0
TX:  bytes  packets  errors  dropped  carrier  collisions
     539     14        0        0         0           0
```

**Connect/Disconnect****disconnect interface <interface>**

Test disconnecting given connection-oriented interface. <interface> can be sstpc0 as the example.

**connect interface <interface>**

Test connecting given connection-oriented interface. <interface> can be sstpc0 as the example.

### 8.4.14 Tunnel

This article touches on ,classic‘ IP tunneling protocols.

GRE is often seen as a one size fits all solution when it comes to classic IP tunneling protocols, and for a good reason. However, there are more specialized options, and many of them are supported by VyOS. There are also rather obscure GRE options that can be useful.

All those protocols are grouped under `interfaces tunnel` in VyOS. Let’s take a closer look at the protocols and options currently supported by VyOS.

#### Common interface configuration

**set interfaces tunnel <interface> address <address>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces tunnel tun0 address 192.0.2.1/24
set interfaces tunnel tun0 address 2001:db8::1/64
```

**set interfaces tunnel <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces tunnel tun0 description 'This is an awesome interface running on VyOS
→ '
```

**set interfaces tunnel <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces tunnel tun0 disable
```

**set interfaces tunnel <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces tunnel tun0 disable-flow-control
```

**set interfaces tunnel <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces tunnel tun0 disable-link-detect
```

#### **set interfaces tunnel <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces tunnel tun0 mtu 1600
```

#### **set interfaces tunnel <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

#### **set interfaces tunnel <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces tunnel tun0 ip arp-cache-timeout 180
```

#### **set interfaces tunnel <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces tunnel tun0 ip disable-arp-filter
```

#### **set interfaces tunnel <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces tunnel tun0 ip disable-forwarding
```

#### **set interfaces tunnel <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces tunnel tun0 ip enable-directed-broadcast
```

#### **set interfaces tunnel <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces tunnel tun0 ip enable-arp-accept
```

#### **set interfaces tunnel <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces tunnel tun0 ip enable-arp-announce
```

#### **set interfaces tunnel <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces tunnel tun0 ip enable-arp-ignore
```

#### **set interfaces tunnel <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces tunnel tun0 ip enable-proxy-arp
```

### set interfaces tunnel <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

### set interfaces tunnel <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

### set interfaces tunnel <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces tunnel tun0 ipv6 address autoconf
```

### set interfaces tunnel <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces tunnel tun0 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces tunnel <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces tunnel tun0 ipv6 address no-default-link-local
```

**set interfaces tunnel <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces tunnel tun0 ipv6 disable-forwarding
```

**set interfaces tunnel <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces tunnel <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces tunnel tun0 ipv6 accept-dad 2
```

**set interfaces tunnel <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces tunnel tun0 ipv6 dup-addr-detect-transmits 5
```

**set interfaces tunnel <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces tunnel tun0 vrf red
```

**IPIP**

This is one of the simplest types of tunnels, as defined by [RFC 2003](#). It takes an IPv4 packet and sends it as a payload of another IPv4 packet. For this reason, there are no other configuration options for this kind of tunnel.

An example:

```
set interfaces tunnel tun0 encapsulation ipip
set interfaces tunnel tun0 source-address 192.0.2.10
set interfaces tunnel tun0 remote 203.0.113.20
set interfaces tunnel tun0 address 192.168.100.200/24
```

**IP6IP6**

This is the IPv6 counterpart of IPIP. I'm not aware of an RFC that defines this encapsulation specifically, but it's a natural specific case of IPv6 encapsulation mechanisms described in [rfc:2473](#).

It's not likely that anyone will need it any time soon, but it does exist.

An example:

```
set interfaces tunnel tun0 encapsulation ip6ip6
set interfaces tunnel tun0 source-address 2001:db8:aa::1
set interfaces tunnel tun0 remote 2001:db8:aa::2
set interfaces tunnel tun0 address 2001:db8:bb::1/64
```

**IPIP6**

In the future this is expected to be a very useful protocol (though there are [other proposals](#)).

As the name implies, it's IPv4 encapsulated in IPv6, as simple as that.

An example:

```
set interfaces tunnel tun0 encapsulation ipip6
set interfaces tunnel tun0 source-address 2001:db8:aa::1
set interfaces tunnel tun0 remote 2001:db8:aa::2
set interfaces tunnel tun0 address 192.168.70.80/24
```

## 6in4 (SIT)

6in4 uses tunneling to encapsulate IPv6 traffic over IPv4 links as defined in [RFC 4213](#). The 6in4 traffic is sent over IPv4 inside IPv4 packets whose IP headers have the IP protocol number set to 41. This protocol number is specifically designated for IPv6 encapsulation, the IPv4 packet header is immediately followed by the IPv6 packet being carried. The encapsulation overhead is the size of the IPv4 header of 20 bytes, therefore with an MTU of 1500 bytes, IPv6 packets of 1480 bytes can be sent without fragmentation. This tunneling technique is frequently used by IPv6 tunnel brokers like [Hurricane Electric](#).

An example:

```
set interfaces tunnel tun0 encapsulation sit
set interfaces tunnel tun0 source-address 192.0.2.10
set interfaces tunnel tun0 remote 192.0.2.20
set interfaces tunnel tun0 address 2001:db8:bb::1/64
```

A full example of a Tunnelbroker.net config can be found at [here](#).

## Generic Routing Encapsulation (GRE)

A GRE tunnel operates at layer 3 of the OSI model and is represented by IP protocol 47. The main benefit of a GRE tunnel is that you are able to carry multiple protocols inside the same tunnel. GRE also supports multicast traffic and supports routing protocols that leverage multicast to form neighbor adjacencies.

A VyOS GRE tunnel can carry both IPv4 and IPv6 traffic and can also be created over either IPv4 (gre) or IPv6 (ip6gre).

## Configuration

A basic configuration requires a tunnel source (source-address), a tunnel destination (remote), an encapsulation type (gre), and an address (ipv4/ipv6). Below is a basic IPv4 only configuration example taken from a VyOS router and a Cisco IOS router. The main difference between these two configurations is that VyOS requires you explicitly configure the encapsulation type. The Cisco router defaults to GRE IP otherwise it would have to be configured as well.

### VyOS Router:

```
set interfaces tunnel tun100 address '10.0.0.1/30'
set interfaces tunnel tun100 encapsulation 'gre'
set interfaces tunnel tun100 source-address '198.51.100.2'
set interfaces tunnel tun100 remote '203.0.113.10'
```

### Cisco IOS Router:

```
interface Tunnel100
ip address 10.0.0.2 255.255.255.252
tunnel source 203.0.113.10
tunnel destination 198.51.100.2
```

Here is a second example of a dual-stack tunnel over IPv6 between a VyOS router and a Linux host using systemd-networkd.

### VyOS Router:

```
set interfaces tunnel tun101 address '2001:db8:feed:beef::1/126'
set interfaces tunnel tun101 address '192.168.5.1/30'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set interfaces tunnel tun101 encapsulation 'ip6gre'
set interfaces tunnel tun101 source-address '2001:db8:babe:face::3afe:3'
set interfaces tunnel tun101 remote '2001:db8:9bb:3ce::5'
```

**Linux systemd-networkd:**

This requires two files, one to create the device (XXX.netdev) and one to configure the network on the device (XXX.network)

```
# cat /etc/systemd/network/gre-example.netdev
[NetDev]
Name=gre-example
Kind=ip6gre
MTUBytes=14180

[Tunnel]
Remote=2001:db8:babe:face::3afe:3

# cat /etc/systemd/network/gre-example.network
[Match]
Name=gre-example

[Network]
Address=2001:db8:feed:beef::2/126

[Address]
Address=192.168.5.2/30
```

**Tunnel keys**

GRE is also the only classic protocol that allows creating multiple tunnels with the same source and destination due to its support for tunnel keys. Despite its name, this feature has nothing to do with security: it's simply an identifier that allows routers to tell one tunnel from another.

An example:

```
set interfaces tunnel tun0 source-address 192.0.2.10
set interfaces tunnel tun0 remote 192.0.2.20
set interfaces tunnel tun0 address 10.40.50.60/24
set interfaces tunnel tun0 parameters ip key 10
```

```
set interfaces tunnel tun0 source-address 192.0.2.10
set interfaces tunnel tun0 remote 192.0.2.20
set interfaces tunnel tun0 address 172.16.17.18/24
set interfaces tunnel tun0 parameters ip key 20
```

## GRETAP

While normal GRE is for layer 3, GRETAP is for layer 2. GRETAP can encapsulate Ethernet frames, thus it can be bridged with other interfaces to create datalink layer segments that span multiple remote sites.

```
set interfaces bridge br0 member interface eth0
set interfaces bridge br0 member interface tun0
set interfaces tunnel tun0 encapsulation gretap
set interfaces tunnel tun0 source-address 198.51.100.2
set interfaces tunnel tun0 remote 203.0.113.10
```

## Troubleshooting

GRE is a well defined standard that is common in most networks. While not inherently difficult to configure there are a couple of things to keep in mind to make sure the configuration performs as expected. A common cause for GRE tunnels to fail to come up correctly include ACL or Firewall configurations that are discarding IP protocol 47 or blocking your source/destination traffic.

### 1. Confirm IP connectivity between tunnel source-address and remote:

```
vyos@vyos:~$ ping 203.0.113.10 interface 198.51.100.2 count 4
PING 203.0.113.10 (203.0.113.10) from 198.51.100.2 : 56(84) bytes of data.
64 bytes from 203.0.113.10: icmp_seq=1 ttl=254 time=0.807 ms
64 bytes from 203.0.113.10: icmp_seq=2 ttl=254 time=1.50 ms
64 bytes from 203.0.113.10: icmp_seq=3 ttl=254 time=0.624 ms
64 bytes from 203.0.113.10: icmp_seq=4 ttl=254 time=1.41 ms

--- 203.0.113.10 ping statistics ---
4 packets transmitted, 4 received, 0% packet loss, time 3007ms
rtt min/avg/max/mdev = 0.624/1.087/1.509/0.381 ms
```

### 2. Confirm the link type has been set to GRE:

```
vyos@vyos:~$ show interfaces tunnel tun100
tun100@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 1476 qdisc noqueue state UNKNOWN group_
↪default qlen 1000
    link/gre 198.51.100.2 peer 203.0.113.10
    inet 10.0.0.1/30 brd 10.0.0.3 scope global tun100
        valid_lft forever preferred_lft forever
    inet6 fe80::5efe:c612:2/64 scope link
        valid_lft forever preferred_lft forever

RX:  bytes    packets    errors    dropped    overrun    mcast
    2183         27         0         0         0         0
TX:  bytes    packets    errors    dropped    carrier    collisions
    836          9         0         0         0         0
```

### 3. Confirm IP connectivity across the tunnel:

```
vyos@vyos:~$ ping 10.0.0.2 interface 10.0.0.1 count 4
PING 10.0.0.2 (10.0.0.2) from 10.0.0.1 : 56(84) bytes of data.
64 bytes from 10.0.0.2: icmp_seq=1 ttl=255 time=1.05 ms
64 bytes from 10.0.0.2: icmp_seq=2 ttl=255 time=1.88 ms
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
64 bytes from 10.0.0.2: icmp_seq=3 ttl=255 time=1.98 ms
64 bytes from 10.0.0.2: icmp_seq=4 ttl=255 time=1.98 ms

--- 10.0.0.2 ping statistics ---
4 packets transmitted, 4 received, 0% packet loss, time 3008ms
rtt min/avg/max/mdev = 1.055/1.729/1.989/0.395 ms
```

---

**Bemerkung:** There is also a GRE over IPv6 encapsulation available, it is called: `ip6gre`.

---

### 8.4.15 Virtual Ethernet

The veth devices are virtual Ethernet devices. They can act as tunnels between network namespaces to create a bridge to a physical network device in another namespace or VRF, but can also be used as standalone network devices.

---

**Bemerkung:** veth interfaces need to be created in pairs - it's called the peer name

---

## Configuration

### Common interface configuration

**set interfaces virtual-ethernet <interface> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
  - /config/scripts/dhcp-client/post-hooks.d/
- 

Example:

```
set interfaces virtual-ethernet veth0 address 192.0.2.1/24
set interfaces virtual-ethernet veth0 address 2001:db8::1/64
set interfaces virtual-ethernet veth0 address dhcp
set interfaces virtual-ethernet veth0 address dhcpv6
```

**set interfaces virtual-ethernet <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces virtual-ethernet veth0 description 'This is an awesome interface.
↳running on VyOS'
```

## VLAN

### Regular VLANs (802.1q)

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

**set interfaces virtual-ethernet <interface> vif <vlan-id>**

Create a new VLAN interface on interface `<interface>` using the VLAN number provided via `<vlan-id>`.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

---

**Bemerkung:** Only 802.1Q-tagged packets are accepted on Ethernet vifs.

---

**set interfaces virtual-ethernet <interface> vif <vlan-id> address <address | dhcp | dhcpv6>**

Configure interface `<interface>` with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
  - /config/scripts/dhcp-client/post-hooks.d/
- 

Example:

```
set interfaces virtual-ethernet veth0 vif 10 address 192.0.2.1/24
set interfaces virtual-ethernet veth0 vif 10 address 2001:db8::1/64
set interfaces virtual-ethernet veth0 vif 10 address dhcp
set interfaces virtual-ethernet veth0 vif 10 address dhcpv6
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 description 'This is an awesome_
↳ interface running on VyOS'
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 disable
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 disable-link-detect
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 mac '00:01:02:03:04:05'
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 mtu 1600
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 ip arp-cache-timeout 180
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 ip disable-arp-filter
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces virtual-ethernet veth0 vif 10 ip disable-forwarding
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces virtual-ethernet veth0 vif 10 ip enable-directed-broadcast
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces virtual-ethernet veth0 vif 10 ip enable-arp-accept
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces virtual-ethernet veth0 vif 10 ip enable-arp-announce
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces virtual-ethernet veth0 vif 10 ip enable-arp-ignore
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 ip enable-proxy-arp
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces virtual-ethernet <interface> vif <vlan-id> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**set interfaces virtual-ethernet <interface> vif <vlan-id> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces virtual-ethernet veth0 vif 10 ipv6 address autoconf
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 ipv6 address no-default-link-local
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 ipv6 disable-forwarding
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces virtual-ethernet <interface> vif <vlan-id> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 ipv6 accept-dad 2
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces virtual-ethernet veth0 vif 10 ipv6 dup-addr-detect-transmits 5
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 vrf red
```

## DHCP(v6)

**set interfaces virtual-ethernet <interface> vif <vlan-id> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier' option. If the client supplies a ,client identifier', the client MUST use the same ,client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 dhcp-options client-id 'foo-bar'
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 dhcp-options host-name 'VyOS'
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 dhcp-options no-default-route
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 dhcp-options default-route-distance 220
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces virtual-ethernet veth0 vif 10 dhcp-options reject 192.168.100.0/24
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces virtual-ethernet veth0 vif 10 dhcp-options user-class VyOS
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its

type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces virtual-ethernet veth0 vif 10 duid
↪ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

#### **set interfaces virtual-ethernet <interface> vif <vlan-id> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces virtual-ethernet veth0 vif 10 dhcpv6-options no-release
```

#### **set interfaces virtual-ethernet <interface> vif <vlan-id> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces virtual-ethernet veth0 vif 10 dhcpv6-options parameters-only
```

#### **set interfaces virtual-ethernet <interface> vif <vlan-id> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces virtual-ethernet veth0 vif 10 dhcpv6-options rapid-commit
```

#### **set interfaces virtual-ethernet <interface> vif <vlan-id> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces virtual-ethernet veth0 vif 10 dhcpv6-options temporary
```

### **DHCPv6 Prefix Delegation (PD)**

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

#### **set interfaces virtual-ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces virtual-ethernet veth0 vif 10 dhcpv6-options pd 0 length 56
```

#### **set interfaces virtual-ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces virtual-ethernet veth0 vif 10 dhcpv6-options pd 0 interface eth8
→address 65534
```

**set interfaces virtual-ethernet <interface> vif <vlan-id> dhcpv6-options pd <id>  
interface <delegate> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:fff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:fff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces virtual-ethernet veth0 vif 10 dhcpv6-options pd 0 interface eth8 sla-
→id 1
```

## QinQ (802.1ad)

IEEE 802.1ad was an Ethernet networking standard informally known as QinQ as an amendment to IEEE standard 802.1q VLAN interfaces as described above. 802.1ad was incorporated into the base 802.1q standard in 2011. The technique is also known as provider bridging, Stacked VLANs, or simply QinQ or Q-in-Q. „Q-in-Q“ can for supported devices apply to C-tag stacking on C-tag (Ethernet Type = 0x8100).

The original 802.1q specification allows a single Virtual Local Area Network (VLAN) header to be inserted into an Ethernet frame. QinQ allows multiple VLAN tags to be inserted into a single frame, an essential capability for implementing Metro Ethernet network topologies. Just as QinQ extends 802.1Q, QinQ itself is extended by other Metro Ethernet protocols.

In a multiple VLAN header context, out of convenience the term „VLAN tag“ or just „tag“ for short is often used in place of „802.1q VLAN header“. QinQ allows multiple VLAN tags in an Ethernet frame; together these tags constitute a tag stack. When used in the context of an Ethernet frame, a QinQ frame is a frame that has 2 VLAN 802.1q headers (double-tagged).

In VyOS the terms vif-s and vif-c stand for the ethertype tags that are used.

The inner tag is the tag which is closest to the payload portion of the frame. It is officially called C-TAG (customer tag, with ethertype 0x8100). The outer tag is the one closer/closest to the Ethernet header, its name is S-TAG (service tag with Ethernet Type = 0x88a8).

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> address  
<address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
- /config/scripts/dhcp-client/post-hooks.d/

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 address 192.0.2.1/24
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 address 2001:db8::1/64
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 address dhcp
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 address dhcpv6
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 description 'This is an
→awesome interface running on VyOS'
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 disable
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 disable-link-detect
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 mac '00:01:02:03:04:05'
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 mtu 1600
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally ,do not try to send me packets bigger than this value‘.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ip arp-cache-timeout 180
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ip disable-arp-filter
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ip disable-forwarding
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ip enable-directed-
→broadcast
```

### **set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ip enable-arp-accept
```

### **set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ip enable-arp-announce
```

### **set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ip enable-arp-ignore
```

### **set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ip enable-proxy-arp
```

### **set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip
source-validation <strict | loose | disable>
```

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address
autoconf
```

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ipv6 address autoconf
```

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address
eui64 <prefix>
```

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ipv6 address eui64_
↪ 2001:db8:beef::/64
```

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address
no-default-link-local
```

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ipv6 address no-default-
↪link-local
```

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6
disable-forwarding
```

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ipv6 disable-forwarding
```

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6
adjust-mss <mss | clamp-mss-to-pmtu>
```

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6
accept-dad <1-3>
```

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ipv6 accept-dad 2
```

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6
dup-addr-detect-transmits <n>
```

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 ipv6 dup-addr-detect-
→transmits 5
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 vrf red
```

## DHCP(v6)

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier' option. If the client supplies a ,client identifier', the client MUST use the same ,client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcp-options client-id
→'foo-bar'
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcp-options host-name
→'VyOS'
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcp-options vendor-class-
→id 'VyOS'
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcp-options no-default-
→route
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcp-options default-
→route-distance 220
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcp-options reject 192.
→168.100.0/24
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcp-options user-class_
→VyOS
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 duid
→'0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcpv6-options no-release
```

**set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcpv6-options parameters-
  ↪ only
```

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options rapid-commit
```

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcpv6-options rapid-
  ↪ commit
```

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options temporary
```

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcpv6-options temporary
```

### DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options pd <id> length <length>
```

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcpv6-options pd 0
  ↪ length 56
```

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options pd <id> interface <delegatee> address <address>
```

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcpv6-options pd 0
  ↪ interface eth8 address 65534
```

```
set interfaces virtual-ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options pd <id> interface <delegatee> sla-id <id>
```

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces virtual-ethernet veth0 vif-s 1000 vif-c 20 dhcpv6-options pd 0
→ interface eth8 sla-id 1
```

### set interfaces virtual-ethernet <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces virtual-ethernet veth0 disable
```

### set interfaces virtual-ethernet <interface> vrf <vrf>

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces virtual-ethernet veth0 vrf red
```

## Operation

### show interfaces virtual-ethernet

Show brief interface information.

```
vyos@vyos:~$ show interfaces virtual-ethernet
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
veth10         100.64.0.0/31   u/u
veth11         100.64.0.1/31   u/u
```

### show interfaces virtual-ethernet <interface>

Show detailed information on given <interface>

```
vyos@vyos:~$ show interfaces virtual-ethernet veth11
10: veth11@veth10: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue master
→red state UP group default qlen 1000
    link/ether b2:7b:df:47:e9:11 brd ff:ff:ff:ff:ff:ff
    inet 100.64.0.1/31 scope global veth11
        valid_lft forever preferred_lft forever
    inet6 fe80::b07b:dfff:fe47:e911/64 scope link
        valid_lft forever preferred_lft forever

RX:  bytes    packets    errors    dropped    overrun    mcast
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

	0	0	0	0	0	0
TX: bytes	packets	errors	dropped	carrier	collisions	
1369707	4267	0	0	0	0	

### Example

Interconnect the global VRF with vrf „red“ using the veth10 <-> veth 11 pair

```
set interfaces virtual-ethernet veth10 address '100.64.0.0/31'
set interfaces virtual-ethernet veth10 peer-name 'veth11'
set interfaces virtual-ethernet veth11 address '100.64.0.1/31'
set interfaces virtual-ethernet veth11 peer-name 'veth10'
set interfaces virtual-ethernet veth11 vrf 'red'
set vrf name red table '1000'
```

```
vyos@vyos:~$ ping 100.64.0.1
PING 100.64.0.1 (100.64.0.1) 56(84) bytes of data.
64 bytes from 100.64.0.1: icmp_seq=1 ttl=64 time=0.080 ms
64 bytes from 100.64.0.1: icmp_seq=2 ttl=64 time=0.119 ms
```

## 8.4.16 VTI - Virtual Tunnel Interface

Set Virtual Tunnel Interface

```
set interfaces vti vti0 address 192.168.2.249/30
set interfaces vti vti0 address 2001:db8:2::249/64
```

Results in:

```
vyos@vyos# show interfaces vti
vti vti0 {
    address 192.168.2.249/30
    address 2001:db8:2::249/64
    description "Description"
}
```

**Warnung:** When using site-to-site IPsec with VTI interfaces, be sure to disable route autoinstall

```
set vpn ipsec options disable-route-autoinstall
```

More details about the IPsec and VTI issue and option disable-route-autoinstall <https://blog.vyos.io/vyos-1-dot-2-0-development-news-in-july>

The root cause of the problem is that for VTI tunnels to work, their traffic selectors have to be set to 0.0.0.0/0 for traffic to match the tunnel, even though actual routing decision is made according to netfilter marks. Unless route insertion is disabled entirely, StrongSWAN thus mistakenly inserts a default route through the VTI peer address, which makes all traffic routed to nowhere.

### 8.4.17 VXLAN

VXLAN is a network virtualization technology that attempts to address the scalability problems associated with large cloud computing deployments. It uses a VLAN-like encapsulation technique to encapsulate OSI layer 2 Ethernet frames within layer 4 UDP datagrams, using 4789 as the default IANA-assigned destination UDP port number. VXLAN endpoints, which terminate VXLAN tunnels and may be either virtual or physical switch ports, are known as VTEPs (VXLAN tunnel endpoints).

VXLAN is an evolution of efforts to standardize an overlay encapsulation protocol. It increases the scalability up to 16 million logical networks and allows for layer 2 adjacency across IP networks. Multicast or unicast with head-end replication (HER) is used to flood broadcast, unknown unicast, and multicast (BUM) traffic.

The VXLAN specification was originally created by VMware, Arista Networks and Cisco. Other backers of the VXLAN technology include Huawei, Broadcom, Citrix, Pica8, Big Switch Networks, Cumulus Networks, Dell EMC, Ericsson, Mellanox, FreeBSD, OpenBSD, Red Hat, Joyent, and Juniper Networks.

VXLAN was officially documented by the IETF in [RFC 7348](#).

If configuring VXLAN in a VyOS virtual machine, ensure that MAC spoofing (Hyper-V) or Forged Transmits (ESX) are permitted, otherwise forwarded frames may be blocked by the hypervisor.

---

**Bemerkung:** As VyOS is based on Linux and there was no official IANA port assigned for VXLAN, VyOS uses a default port of 8472. You can change the port on a per VXLAN interface basis to get it working across multiple vendors.

---

## Configuration

### Common interface configuration

**set interfaces vxlan <interface> address <address>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces vxlan vxlan0 address 192.0.2.1/24
set interfaces vxlan vxlan0 address 2001:db8::1/64
```

**set interfaces vxlan <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces vxlan vxlan0 description 'This is an awesome interface running on
↳ VyOS'
```

**set interfaces vxlan <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces vxlan vxlan0 disable
```

### **set interfaces vxlan <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces vxlan vxlan0 disable-flow-control
```

### **set interfaces vxlan <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces vxlan vxlan0 disable-link-detect
```

### **set interfaces vxlan <interface> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces vxlan vxlan0 mac '00:01:02:03:04:05'
```

### **set interfaces vxlan <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces vxlan vxlan0 mtu 1600
```

### **set interfaces vxlan <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally, 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces vxlan <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces vxlan vxlan0 ip arp-cache-timeout 180
```

**set interfaces vxlan <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces vxlan vxlan0 ip disable-arp-filter
```

**set interfaces vxlan <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces vxlan vxlan0 ip disable-forwarding
```

**set interfaces vxlan <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces vxlan vxlan0 ip enable-directed-broadcast
```

**set interfaces vxlan <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces vxlan vxlan0 ip enable-arp-accept
```

**set interfaces vxlan <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces vxlan vxlan0 ip enable-arp-announce
```

#### **set interfaces vxlan <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces vxlan vxlan0 ip enable-arp-ignore
```

#### **set interfaces vxlan <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces vxlan vxlan0 ip enable-proxy-arp
```

#### **set interfaces vxlan <interface> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

#### **set interfaces vxlan <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.

- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

#### **set interfaces vxlan <interface> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces vxlan vxlan0 ipv6 address autoconf
```

#### **set interfaces vxlan <interface> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces vxlan vxlan0 ipv6 address eui64 2001:db8:beef::/64
```

#### **set interfaces vxlan <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces vxlan vxlan0 ipv6 address no-default-link-local
```

#### **set interfaces vxlan <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces vxlan vxlan0 ipv6 disable-forwarding
```

#### **set interfaces vxlan <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces vxlan <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces vxlan vxlan0 ipv6 accept-dad 2
```

**set interfaces vxlan <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces vxlan vxlan0 ipv6 dup-addr-detect-transmits 5
```

**set interfaces vxlan <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces vxlan vxlan0 vrf red
```

## VXLAN specific options

**set interfaces vxlan <interface> vni <number>**

Each VXLAN segment is identified through a 24-bit segment ID, termed the VNI, This allows up to 16M VXLAN segments to coexist within the same administrative domain.

**set interfaces vxlan <interface> port <port>**

Configure port number of remote VXLAN endpoint.

---

**Bemerkung:** As VyOS is Linux based the default port used is not using 4789 as the default IANA-assigned destination UDP port number. Instead VyOS uses the Linux default port of 8472.

---

**set interfaces vxlan <interface> source-address <interface>**

Source IP address used for VXLAN underlay. This is mandatory when using VXLAN via L2VPN/EVPN.

**set interfaces vxlan <interface> gpe**

Enables the Generic Protocol extension (VXLAN-GPE). Currently, this is only supported together with the external keyword.

**set interfaces vxlan <interface> parameters external**

Specifies whether an external control plane (e.g. BGP L2VPN/EVPN) or the internal FDB should be used.

**set interfaces vxlan <interface> parameters neighbor-suppress**

In order to minimize the flooding of ARP and ND messages in the VXLAN network, EVPN includes provisions [RFC 7432#section-10](#) that allow participating VTEPs to suppress such messages in case they know the MAC-IP binding and can reply on behalf of the remote host.

**set interfaces vxlan <interface> parameters nolearning**

Specifies if unknown source link layer addresses and IP addresses are entered into the VXLAN device forwarding database.

**set interfaces vxlan <interface> parameters vni-filter**

Specifies whether the VXLAN device is capable of vni filtering.

Only works with a VXLAN device with external flag set.

---

**Bemerkung:** The device can only receive packets with VNIs configured in the VNI filtering table.

---

## Unicast

**set interfaces vxlan <interface> remote <address>**

IPv4/IPv6 remote address of the VXLAN tunnel. Alternative to multicast, the remote IPv4/IPv6 address can set directly.

## Multicast

**set interfaces vxlan <interface> source-interface <interface>**

Interface used for VXLAN underlay. This is mandatory when using VXLAN via a multicast network. VXLAN traffic will always enter and exit this interface.

**set interfaces vxlan <interface> group <address>**

Multicast group address for VXLAN interface. VXLAN tunnels can be built either via Multicast or via Unicast.

Both IPv4 and IPv6 multicast is possible.

## Multicast VXLAN

Topology: PC4 - Leaf2 - Spine1 - Leaf3 - PC5

PC4 has IP 10.0.0.4/24 and PC5 has IP 10.0.0.5/24, so they believe they are in the same broadcast domain.

Let's assume PC4 on Leaf2 wants to ping PC5 on Leaf3. Instead of setting Leaf3 as our remote end manually, Leaf2 encapsulates the packet into a UDP-packet and sends it to its designated multicast-address via Spine1. When Spine1 receives this packet it forwards it to all other leaves who has joined the same multicast-group, in this case Leaf3. When Leaf3 receives the packet it forwards it, while at the same time learning that PC4 is reachable behind Leaf2, because the encapsulated packet had Leaf2's IP address set as source IP.

PC5 receives the ping echo, responds with an echo reply that Leaf3 receives and this time forwards to Leaf2's unicast address directly because it learned the location of PC4 above. When Leaf2 receives the echo reply from PC5 it sees that it came from Leaf3 and so remembers that PC5 is reachable via Leaf3.

Thanks to this discovery, any subsequent traffic between PC4 and PC5 will not be using the multicast-address between the leaves as they both know behind which Leaf the PCs are connected. This saves traffic as less multicast packets sent reduces the load on the network, which improves scalability when more leaves are added.

For optimal scalability, Multicast shouldn't be used at all, but instead use BGP to signal all connected devices between leaves. Unfortunately, VyOS does not yet support this.

### Single VXLAN device (SVD)

FRR supports a new way of configuring VLAN-to-VNI mappings for EVPN-VXLAN, when working with the Linux kernel. In this new way, the mapping of a VLAN to a VNI is configured against a container VXLAN interface which is referred to as a SVD (Single VXLAN device).

Multiple VLAN to VNI mappings can be configured against the same SVD. This allows for a significant scaling of the number of VNIs since a separate VXLAN interface is no longer required for each VNI.

**set interfaces vxlan <interface> vlan-to-vni <vlan> vni <vni>**

Maps the VNI to the specified VLAN id. The VLAN can then be consumed by a bridge.

Sample configuration of SVD with VLAN to VNI mappings is shown below.

```
set interfaces bridge br0 member interface vxlan0
set interfaces vxlan vxlan0 parameters external
set interfaces vxlan vxlan0 source-interface 'dum0'
set interfaces vxlan vxlan0 vlan-to-vni 10 vni '10010'
set interfaces vxlan vxlan0 vlan-to-vni 11 vni '10011'
set interfaces vxlan vxlan0 vlan-to-vni 30 vni '10030'
set interfaces vxlan vxlan0 vlan-to-vni 31 vni '10031'
```

### Example

The setup is this: Leaf2 - Spine1 - Leaf3

Spine1 is a Cisco IOS router running version 15.4, Leaf2 and Leaf3 is each a VyOS router running 1.2.

This topology was built using GNS3.

Topology:

```
Spine1:
fa0/2 towards Leaf2, IP-address: 10.1.2.1/24
fa0/3 towards Leaf3, IP-address: 10.1.3.1/24

Leaf2:
Eth0 towards Spine1, IP-address: 10.1.2.2/24
Eth1 towards a vlan-aware switch

Leaf3:
Eth0 towards Spine1, IP-address 10.1.3.3/24
Eth1 towards a vlan-aware switch
```

**Spine1 Configuration:**

```

conf t
ip multicast-routing
!
interface fastethernet0/2
ip address 10.1.2.1 255.255.255.0
ip pim sparse-dense-mode
!
interface fastethernet0/3
ip address 10.1.3.1 255.255.255.0
ip pim sparse-dense-mode
!
router ospf 1
network 10.0.0.0 0.255.255.255 area 0

```

Multicast-routing is required for the leaves to forward traffic between each other in a more scalable way. This also requires PIM to be enabled towards the leaves so that the Spine can learn what multicast groups each Leaf expects traffic from.

#### Leaf2 configuration:

```

set interfaces ethernet eth0 address '10.1.2.2/24'
set protocols ospf area 0 network '10.0.0.0/8'

! Our first vxlan interface
set interfaces bridge br241 address '172.16.241.1/24'
set interfaces bridge br241 member interface 'eth1.241'
set interfaces bridge br241 member interface 'vxlan241'

set interfaces vxlan vxlan241 group '239.0.0.241'
set interfaces vxlan vxlan241 source-interface 'eth0'
set interfaces vxlan vxlan241 vni '241'

! Our seconds vxlan interface
set interfaces bridge br242 address '172.16.242.1/24'
set interfaces bridge br242 member interface 'eth1.242'
set interfaces bridge br242 member interface 'vxlan242'

set interfaces vxlan vxlan242 group '239.0.0.242'
set interfaces vxlan vxlan242 source-interface 'eth0'
set interfaces vxlan vxlan242 vni '242'

```

#### Leaf3 configuration:

```

set interfaces ethernet eth0 address '10.1.3.3/24'
set protocols ospf area 0 network '10.0.0.0/8'

! Our first vxlan interface
set interfaces bridge br241 address '172.16.241.1/24'
set interfaces bridge br241 member interface 'eth1.241'
set interfaces bridge br241 member interface 'vxlan241'

set interfaces vxlan vxlan241 group '239.0.0.241'
set interfaces vxlan vxlan241 source-interface 'eth0'
set interfaces vxlan vxlan241 vni '241'

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
! Our seconds vxlan interface
set interfaces bridge br242 address '172.16.242.1/24'
set interfaces bridge br242 member interface 'eth1.242'
set interfaces bridge br242 member interface 'vxlan242'

set interfaces vxlan vxlan242 group '239.0.0.242'
set interfaces vxlan vxlan242 source-interface 'eth0'
set interfaces vxlan vxlan242 vni '242'
```

As you can see, Leaf2 and Leaf3 configuration is almost identical. There are lots of commands above, I'll try to into more detail below, command descriptions are placed under the command boxes:

```
set interfaces bridge br241 address '172.16.241.1/24'
```

This commands creates a bridge that is used to bind traffic on eth1 vlan 241 with the vxlan241-interface. The IP address is not required. It may however be used as a default gateway for each Leaf which allows devices on the vlan to reach other subnets. This requires that the subnets are redistributed by OSPF so that the Spine will learn how to reach it. To do this you need to change the OSPF network from ,10.0.0.0/8' to ,0.0.0.0/0' to allow 172.16/12-networks to be advertised.

```
set interfaces bridge br241 member interface 'eth1.241'
set interfaces bridge br241 member interface 'vxlan241'
```

Binds eth1.241 and vxlan241 to each other by making them both member interfaces of the same bridge.

```
set interfaces vxlan vxlan241 group '239.0.0.241'
```

The multicast-group used by all leaves for this vlan extension. Has to be the same on all leaves that has this interface.

```
set interfaces vxlan vxlan241 source-interface 'eth0'
```

Sets the interface to listen for multicast packets on. Could be a loopback, not yet tested.

```
set interfaces vxlan vxlan241 vni '241'
```

Sets the unique id for this vxlan-interface. Not sure how it correlates with multicast-address.

```
set interfaces vxlan vxlan241 port 12345
```

The destination port used for creating a VXLAN interface in Linux defaults to its pre-standard value of 8472 to preserve backward compatibility. A configuration directive to support a user-specified destination port to override that behavior is available using the above command.

## Unicast VXLAN

Alternative to multicast, the remote IPv4 address of the VXLAN tunnel can be set directly. Let's change the Multicast example from above:

```
# leaf2 and leaf3
delete interfaces vxlan vxlan241 group '239.0.0.241'
delete interfaces vxlan vxlan241 source-interface 'eth0'

# leaf2
set interface vxlan vxlan241 remote 10.1.3.3

# leaf3
set interface vxlan vxlan241 remote 10.1.2.2
```

The default port udp is set to 8472. It can be changed with `set interface vxlan <vxlanN> port <port>`

### 8.4.18 WLAN/WIFI - Wireless LAN

WLAN (Wireless LAN) interface provide 802.11 (a/b/g/n/ac) wireless support (commonly referred to as Wi-Fi) by means of compatible hardware. If your hardware supports it, VyOS supports multiple logical wireless interfaces per physical device.

There are three modes of operation for a wireless interface:

- WAP (Wireless Access-Point) provides network access to connecting stations if the physical hardware supports acting as a WAP
- A station acts as a Wi-Fi client accessing the network through an available WAP
- Monitor, the system passively monitors any kind of wireless traffic

If the system detects an unconfigured wireless device, it will be automatically added the configuration tree, specifying any detected settings (for example, its MAC address) and configured to run in monitor mode.

## Configuration

### Common interface configuration

**set interfaces wireless <interface> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
- /config/scripts/dhcp-client/post-hooks.d/

Example:

```
set interfaces wireless wlan0 address 192.0.2.1/24
set interfaces wireless wlan0 address 2001:db8::1/64
set interfaces wireless wlan0 address dhcp
set interfaces wireless wlan0 address dhcpv6
```

### **set interfaces wireless <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces wireless wlan0 description 'This is an awesome interface running on
↳ VyOS'
```

### **set interfaces wireless <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces wireless wlan0 disable
```

### **set interfaces wireless <interface> disable-flow-control**

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces wireless wlan0 disable-flow-control
```

### **set interfaces wireless <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces wireless wlan0 disable-link-detect
```

### **set interfaces wireless <interface> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces wireless wlan0 mac '00:01:02:03:04:05'
```

**set interfaces wireless <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces wireless wlan0 mtu 1600
```

**set interfaces wireless <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces wireless <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces wireless wlan0 ip arp-cache-timeout 180
```

**set interfaces wireless <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces wireless wlan0 ip disable-arp-filter
```

**set interfaces wireless <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces wireless wlan0 ip disable-forwarding
```

**set interfaces wireless <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces wireless wlan0 ip enable-directed-broadcast
```

#### **set interfaces wireless <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces wireless wlan0 ip enable-arp-accept
```

#### **set interfaces wireless <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces wireless wlan0 ip enable-arp-announce
```

#### **set interfaces wireless <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces wireless wlan0 ip enable-arp-ignore
```

#### **set interfaces wireless <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces wireless wlan0 ip enable-proxy-arp
```

#### **set interfaces wireless <interface> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces wireless <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**set interfaces wireless <interface> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces wireless wlan0 ipv6 address autoconf
```

**set interfaces wireless <interface> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces wireless wlan0 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces wireless <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces wireless wlan0 ipv6 address no-default-link-local
```

### **set interfaces wireless <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces wireless wlan0 ipv6 disable-forwarding
```

### **set interfaces wireless <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

### **set interfaces wireless <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces wireless wlan0 ipv6 accept-dad 2
```

### **set interfaces wireless <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces wireless wlan0 ipv6 dup-addr-detect-transmits 5
```

### **set interfaces wireless <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces wireless wlan0 vrf red
```

## **DHCP(v6)**

**set interfaces wireless <interface> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier‘ option. If the client supplies a ,client identifier‘, the client MUST use the same ,client identifier‘ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces wireless wlan0 dhcp-options client-id 'foo-bar'
```

**set interfaces wireless <interface> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces wireless wlan0 dhcp-options host-name 'VyOS'
```

**set interfaces wireless <interface> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces wireless wlan0 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces wireless <interface> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces wireless wlan0 dhcp-options no-default-route
```

**set interfaces wireless <interface> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces wireless wlan0 dhcp-options default-route-distance 220
```

**set interfaces wireless <interface> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces wireless wlan0 dhcp-options reject 192.168.100.0/24
```

**set interfaces wireless <interface> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces wireless wlan0 dhcp-options user-class VyOS
```

#### **set interfaces wireless <interface> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces wireless wlan0 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

#### **set interfaces wireless <interface> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces wireless wlan0 dhcpv6-options no-release
```

#### **set interfaces wireless <interface> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces wireless wlan0 dhcpv6-options parameters-only
```

#### **set interfaces wireless <interface> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces wireless wlan0 dhcpv6-options rapid-commit
```

#### **set interfaces wireless <interface> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces wireless wlan0 dhcpv6-options temporary
```

### **DHCPv6 Prefix Delegation (PD)**

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

#### **set interfaces wireless <interface> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces wireless wlan0 dhcpv6-options pd 0 length 56
```

**set interfaces wireless <interface> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces wireless wlan0 dhcpv6-options pd 0 interface eth8 address 65534
```

**set interfaces wireless <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:fff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:fff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces wireless wlan0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## Wireless options

**set interfaces wireless <interface> channel <number>**

Channel number (IEEE 802.11), for 2.4Ghz (802.11 b/g/n) channels range from 1-14. On 5Ghz (802.11 a/h/j/n/ac) channels available are 0, 34 to 173

**set interfaces wireless <interface> country-code <cc>**

Country code (ISO/IEC 3166-1). Used to set regulatory domain. Set as needed to indicate country in which device is operating. This can limit available channels and transmit power.

---

**Bemerkung:** This option is mandatory in Access-Point mode.

---

**set interfaces wireless <interface> disable-broadcast-ssid**

Send empty SSID in beacons and ignore probe request frames that do not specify full SSID, i.e., require stations to know SSID.

**set interfaces wireless <interface> expunge-failing-stations**

Disassociate stations based on excessive transmission failures or other indications of connection loss.

This depends on the driver capabilities and may not be available with all drivers.

**set interfaces wireless <interface> isolate-stations**

Client isolation can be used to prevent low-level bridging of frames between associated stations in the BSS.

By default, this bridging is allowed.

**set interfaces wireless <interface> max-stations**

Maximum number of stations allowed in station table. New stations will be rejected after the station table is full. IEEE 802.11 has a limit of 2007 different association IDs, so this number should not be larger than that.

This defaults to 2007.

**set interfaces wireless <interface> mgmt-frame-protection**

Management Frame Protection (MFP) according to IEEE 802.11w

**set interfaces wireless <interface> mode <a | b | g | n | ac>**

Operation mode of wireless radio.

- a - 802.11a - 54 Mbits/sec
- b - 802.11b - 11 Mbits/sec
- g - 802.11g - 54 Mbits/sec (default)
- n - 802.11n - 600 Mbits/sec
- ac - 802.11ac - 1300 Mbits/sec

**set interfaces wireless <interface> physical-device <device>**

Wireless hardware device used as underlay radio.

This defaults to phy0.

**set interfaces wireless <interface> reduce-transmit-power <number>**

Add Power Constraint element to Beacon and Probe Response frames.

This option adds Power Constraint element when applicable and Country element is added. Power Constraint element is required by Transmit Power Control.

Valid values are 0..255.

**set interfaces wireless <interface> ssid <ssid>**

SSID to be used in IEEE 802.11 management frames

**set interfaces wireless <interface> type <access-point | station | monitor>**

Wireless device type for this interface

- access-point - Access-point forwards packets between other nodes
- station - Connects to another access point
- monitor - Passively monitor all packets on the frequency/channel

**set interfaces wireless <interface> per-client-thread**

Provides a per-device control to enable/disable the threaded mode for all the NAPI instances of the given network device, without the need for a device up/down.

If CLI option is not specified, this feature is disabled.

Example:

```
set interfaces wireless wlan0 per-client-thread
```

## PPDU

```
set interfaces wireless <interface> capabilities require-ht
```

```
set interfaces wireless <interface> capabilities require-hvt
```

## HT (High Throughput) capabilities (802.11n)

```
set interfaces wireless <interface> capabilities ht 40mhz-incapable
```

Device is incapable of 40 MHz, do not advertise. This sets [40-INTOLERANT]

```
set interfaces wireless <interface> capabilities ht auto-powersave
```

WMM-PS Unscheduled Automatic Power Save Delivery [U-APSD]

```
set interfaces wireless <interface> capabilities ht channel-set-width <ht20 | ht40+ | ht40->
```

Supported channel width set.

- ht40- - Both 20 MHz and 40 MHz with secondary channel below the primary channel
- ht40+ - Both 20 MHz and 40 MHz with secondary channel above the primary channel

**Bemerkung:** There are limits on which channels can be used with HT40- and HT40+. Following table shows the channels that may be available for HT40- and HT40+ use per IEEE 802.11n Annex J:

Depending on the location, not all of these channels may be available for use!

freq	HT40-	HT40+
2.4 GHz	5-13	1-7 (1-9 in Europe/Japan)
5 GHz	40, 48, 56, 64	36, 44, 52, 60

**Bemerkung:** 40 MHz channels may switch their primary and secondary channels if needed or creation of 40 MHz channel maybe rejected based on overlapping BSSes. These changes are done automatically when hostapd is setting up the 40 MHz channel.

```
set interfaces wireless <interface> capabilities ht delayed-block-ack
```

Enable HT-delayed Block Ack [DELAYED-BA]

```
set interfaces wireless <interface> capabilities ht dsss-cck-40
```

DSSS/CCK Mode in 40 MHz, this sets [DSSS\_CCK-40]

```
set interfaces wireless <interface> capabilities ht greenfield
```

This enables the greenfield option which sets the [GF] option

```
set interfaces wireless <interface> capabilities ht ldpc
```

Enable LDPC coding capability

```
set interfaces wireless <interface> capabilities ht lsig-protection
```

Enable L-SIG TXOP protection capability

```
set interfaces wireless <interface> capabilities ht max-amsdu <3839 | 7935>
```

Maximum A-MSDU length 3839 (default) or 7935 octets

```
set interfaces wireless <interface> capabilities ht short-gi <20 | 40>
```

Short GI capabilities for 20 and 40 MHz

```
set interfaces wireless <interface> capabilities ht smps <static | dynamic>
```

Spatial Multiplexing Power Save (SMPS) settings

```
set interfaces wireless <interface> capabilities ht stbc rx <num>
```

Enable receiving PPDU using STBC (Space Time Block Coding)

```
set interfaces wireless <interface> capabilities ht stbc tx
```

Enable sending PPDU using STBC (Space Time Block Coding)

### VHT (Very High Throughput) capabilities (802.11ac)

```
set interfaces wireless <interface> capabilities vht antenna-count
```

Number of antennas on this card

```
set interfaces wireless <interface> capabilities vht antenna-pattern-fixed
```

Set if antenna pattern does not change during the lifetime of an association

```
set interfaces wireless <interface> capabilities vht beamform <single-user-beamformer |  
single-user-beamformee | multi-user-beamformer | multi-user-beamformee>
```

Beamforming capabilities:

- single-user-beamformer - Support for operation as single user beamformer
- single-user-beamformee - Support for operation as single user beamformee
- multi-user-beamformer - Support for operation as single user beamformer
- multi-user-beamformee - Support for operation as single user beamformer

```
set interfaces wireless <interface> capabilities vht center-channel-freq <freq-1 |  
freq-2> <number>
```

VHT operating channel center frequency - center freq 1 (for use with 80, 80+80 and 160 modes)

VHT operating channel center frequency - center freq 2 (for use with the 80+80 mode)

<number> must be from 34 - 173. For 80 MHz channels it should be channel + 6.

```
set interfaces wireless <interface> capabilities vht channel-set-width <0 | 1 | 2 | 3>
```

- 0 - 20 or 40 MHz channel width (default)
- 1 - 80 MHz channel width
- 2 - 160 MHz channel width
- 3 - 80+80 MHz channel width

```
set interfaces wireless <interface> capabilities vht ldpc
```

Enable LDPC (Low Density Parity Check) coding capability

```
set interfaces wireless <interface> capabilities vht link-adaptation
```

VHT link adaptation capabilities

```
set interfaces wireless <interface> capabilities vht max-mpdu <value>
```

Increase Maximum MPDU length to 7991 or 11454 octets (default 3895 octets)

```
set interfaces wireless <interface> capabilities vht max-mpdu-exp <value>
```

Set the maximum length of A-MPDU pre-EOF padding that the station can receive

```
set interfaces wireless <interface> capabilities vht short-gi <80 | 160>
```

Short GI capabilities

```
set interfaces wireless <interface> capabilities vht stbc rx <num>
```

Enable receiving PPDU using STBC (Space Time Block Coding)

```
set interfaces wireless <interface> capabilities vht stbc tx
```

Enable sending PPDU using STBC (Space Time Block Coding)

```
set interfaces wireless <interface> capabilities vht tx-powersave
```

Enable VHT TXOP Power Save Mode

```
set interfaces wireless <interface> capabilities vht vht-cf
```

Station supports receiving VHT variant HT Control field

### Wireless options (Station/Client)

The example creates a wireless station (commonly referred to as Wi-Fi client) that accesses the network through the WAP defined in the above example. The default physical device (phy0) is used.

```
set interfaces wireless wlan0 type station
set interfaces wireless wlan0 address dhcp
set interfaces wireless wlan0 country-code de
set interfaces wireless wlan0 ssid Test
set interfaces wireless wlan0 security wpa passphrase '12345678'
```

Resulting in

```
interfaces {
  [...]
  wireless wlan0 {
    address dhcp
    country-code de
    security {
      wpa {
        passphrase "12345678"
      }
    }
    ssid TEST
    type station
  }
}
```

## Security

WPA (Wi-Fi Protected Access) and WPA2 Enterprise in combination with 802.1x based authentication can be used to authenticate users or computers in a domain.

The wireless client (supplicant) authenticates against the RADIUS server (authentication server) using an EAP method configured on the RADIUS server. The WAP (also referred to as authenticator) role is to send all authentication messages between the supplicant and the configured authentication server, thus the RADIUS server is responsible for authenticating the users.

The WAP in this example has the following characteristics:

- IP address 192.168.2.1/24
- Network ID (SSID) Enterprise-TEST
- WPA passphrase 12345678
- Use 802.11n protocol
- Wireless channel 1
- RADIUS server at 192.168.3.10 with shared-secret VyOSPassword

```
set interfaces wireless wlan0 address '192.168.2.1/24'
set interfaces wireless wlan0 country-code de
set interfaces wireless wlan0 type access-point
set interfaces wireless wlan0 channel 1
set interfaces wireless wlan0 mode n
set interfaces wireless wlan0 ssid 'TEST'
set interfaces wireless wlan0 security wpa mode wpa2
set interfaces wireless wlan0 security wpa cipher CCMP
set interfaces wireless wlan0 security wpa radius server 192.168.3.10 key 'VyOSPassword'
set interfaces wireless wlan0 security wpa radius server 192.168.3.10 port 1812
```

Resulting in

```
interfaces {
  [...]
  wireless wlan0 {
    address 192.168.2.1/24
    country-code de
    channel 1
    mode n
    security {
      wpa {
        cipher CCMP
        mode wpa2
        radius {
          server 192.168.3.10 {
            key 'VyOSPassword'
            port 1812
          }
        }
      }
    }
    ssid "Enterprise-TEST"
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

    type access-point
  }
}

```

## VLAN

### Regular VLANs (802.1q)

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

**set interfaces wireless <interface> vif <vlan-id>**

Create a new VLAN interface on interface `<interface>` using the VLAN number provided via `<vlan-id>`.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

---

**Bemerkung:** Only 802.1Q-tagged packets are accepted on Ethernet vifs.

---

**set interfaces wireless <interface> vif <vlan-id> address <address | dhcp | dhcpv6>**

Configure interface `<interface>` with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- `/config/scripts/dhcp-client/pre-hooks.d/`
  - `/config/scripts/dhcp-client/post-hooks.d/`
- 

Example:

```
set interfaces wireless wlan0 vif 10 address 192.0.2.1/24
set interfaces wireless wlan0 vif 10 address 2001:db8::1/64
set interfaces wireless wlan0 vif 10 address dhcp
set interfaces wireless wlan0 vif 10 address dhcpv6
```

### **set interfaces wireless <interface> vif <vlan-id> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces wireless wlan0 vif 10 description 'This is an awesome interface,
↳ running on VyOS'
```

### **set interfaces wireless <interface> vif <vlan-id> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces wireless wlan0 vif 10 disable
```

### **set interfaces wireless <interface> vif <vlan-id> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces wireless wlan0 vif 10 disable-link-detect
```

### **set interfaces wireless <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces wireless wlan0 vif 10 mac '00:01:02:03:04:05'
```

### **set interfaces wireless <interface> vif <vlan-id> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces wireless wlan0 vif 10 mtu 1600
```

### **set interfaces wireless <interface> vif <vlan-id> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces wireless <interface> vif <vlan-id> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces wireless wlan0 vif 10 ip arp-cache-timeout 180
```

**set interfaces wireless <interface> vif <vlan-id> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces wireless wlan0 vif 10 ip disable-arp-filter
```

**set interfaces wireless <interface> vif <vlan-id> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces wireless wlan0 vif 10 ip disable-forwarding
```

**set interfaces wireless <interface> vif <vlan-id> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces wireless wlan0 vif 10 ip enable-directed-broadcast
```

**set interfaces wireless <interface> vif <vlan-id> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces wireless wlan0 vif 10 ip enable-arp-accept
```

**set interfaces wireless <interface> vif <vlan-id> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces wireless wlan0 vif 10 ip enable-arp-announce
```

**set interfaces wireless <interface> vif <vlan-id> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces wireless wlan0 vif 10 ip enable-arp-ignore
```

**set interfaces wireless <interface> vif <vlan-id> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces wireless wlan0 vif 10 ip enable-proxy-arp
```

**set interfaces wireless <interface> vif <vlan-id> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces wireless <interface> vif <vlan-id> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**set interfaces wireless <interface> vif <vlan-id> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 address autoconf
```

**set interfaces wireless <interface> vif <vlan-id> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces wireless <interface> vif <vlan-id> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 address no-default-link-local
```

**set interfaces wireless <interface> vif <vlan-id> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 disable-forwarding
```

**set interfaces wireless <interface> vif <vlan-id> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces wireless <interface> vif <vlan-id> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 accept-dad 2
```

**set interfaces wireless <interface> vif <vlan-id> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 dup-addr-detect-transmits 5
```

**set interfaces wireless <interface> vif <vlan-id> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces wireless wlan0 vif 10 vrf red
```

## DHCP(v6)

**set interfaces wireless <interface> vif <vlan-id> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier' option. If the client supplies a ,client identifier', the client MUST use the same ,client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options client-id 'foo-bar'
```

**set interfaces wireless <interface> vif <vlan-id> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options host-name 'VyOS'
```

**set interfaces wireless <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces wireless <interface> vif <vlan-id> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options no-default-route
```

**set interfaces wireless <interface> vif <vlan-id> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options default-route-distance 220
```

**set interfaces wireless <interface> vif <vlan-id> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options reject 192.168.100.0/24
```

**set interfaces wireless <interface> vif <vlan-id> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options user-class VyOS
```

**set interfaces wireless <interface> vif <vlan-id> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces wireless wlan0 vif 10 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

#### **set interfaces wireless <interface> vif <vlan-id> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options no-release
```

#### **set interfaces wireless <interface> vif <vlan-id> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options parameters-only
```

#### **set interfaces wireless <interface> vif <vlan-id> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options rapid-commit
```

#### **set interfaces wireless <interface> vif <vlan-id> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options temporary
```

### **DHCPv6 Prefix Delegation (PD)**

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

#### **set interfaces wireless <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces wireless wlan0 vif 10 dhcpv6-options pd 0 length 56
```

#### **set interfaces wireless <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options pd 0 interface eth8 address 192.168.1.65534
```

```
set interfaces wireless <interface> vif <vlan-id> dhcpv6-options pd <id> interface
<delegatee> sla-id <id>
```

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## QinQ (802.1ad)

IEEE 802.1ad was an Ethernet networking standard informally known as QinQ as an amendment to IEEE standard 802.1q VLAN interfaces as described above. 802.1ad was incorporated into the base 802.1q standard in 2011. The technique is also known as provider bridging, Stacked VLANs, or simply QinQ or Q-in-Q. „Q-in-Q“ can for supported devices apply to C-tag stacking on C-tag (Ethernet Type = 0x8100).

The original 802.1q specification allows a single Virtual Local Area Network (VLAN) header to be inserted into an Ethernet frame. QinQ allows multiple VLAN tags to be inserted into a single frame, an essential capability for implementing Metro Ethernet network topologies. Just as QinQ extends 802.1Q, QinQ itself is extended by other Metro Ethernet protocols.

In a multiple VLAN header context, out of convenience the term „VLAN tag“ or just „tag“ for short is often used in place of „802.1q VLAN header“. QinQ allows multiple VLAN tags in an Ethernet frame; together these tags constitute a tag stack. When used in the context of an Ethernet frame, a QinQ frame is a frame that has 2 VLAN 802.1q headers (double-tagged).

In VyOS the terms `vif-s` and `vif-c` stand for the ethertype tags that are used.

The inner tag is the tag which is closest to the payload portion of the frame. It is officially called C-TAG (customer tag, with ethertype 0x8100). The outer tag is the one closer/closest to the Ethernet header, its name is S-TAG (service tag with Ethernet Type = 0x88a8).

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> address <address |
dhcp | dhcpv6>
```

Configure interface `<interface>` with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
- /config/scripts/dhcp-client/post-hooks.d/

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 address 192.0.2.1/24
set interfaces wireless wlan0 vif-s 1000 vif-c 20 address 2001:db8::1/64
set interfaces wireless wlan0 vif-s 1000 vif-c 20 address dhcp
set interfaces wireless wlan0 vif-s 1000 vif-c 20 address dhcpv6
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 description 'This is an awesome
↳ interface running on VyOS'
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 disable
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 disable-link-detect
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> mac <xx:xx:xx:xx:xx:xx>**

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 mac '00:01:02:03:04:05'
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 mtu 1600
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip arp-cache-timeout 180
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip disable-arp-filter
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip disable-forwarding
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip enable-directed-broadcast
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip enable-arp-accept
```

### **set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip enable-arp-announce
```

### **set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip enable-arp-ignore
```

### **set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip enable-proxy-arp
```

### **set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN

- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 address autoconf
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 address eui64 ↵
↵ 2001:db8:beef::/64
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 address no-default-link-local
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 disable-forwarding
```

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 adjust-mss <mss>
| clamp-mss-to-pmtu>
```

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 accept-dad <1-3>
```

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 accept-dad 2
```

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6
dup-addr-detect-transmits <n>
```

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 dup-addr-detect-transmits 5
```

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> vrf <vrf>
```

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 vrf red
```

## DHCP(v6)

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options
client-id <description>
```

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier' option. If the client supplies a ,client identifier', the client MUST use the same ,client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options client-id 'foo-bar'
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options host-name 'VyOS'
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options vendor-class-id 'VyOS
→ '
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options no-default-route
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options default-route-
→ distance 220
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options reject 192.168.100.0/
↪ 24
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options user-class VyOS
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 duid
↪ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options no-release
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options parameters-only
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options rapid-commit
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options temporary
```

## DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options pd
<id> length <length>
```

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 length 56
```

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options pd
<id> interface <delegatee> address <address>
```

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 interface_
→eth8 address 65534
```

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcpv6-options pd
<id> interface <delegatee> sla-id <id>
```

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:fff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:fff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 interface_
→eth8 sla-id 1
```

## Operation

### show interfaces wireless info

Use this command to view operational status and wireless-specific information about all wireless interfaces.

```
vyos@vyos:~$ show interfaces wireless info
Interface  Type      SSID          Channel
wlan0      access-point  VyOS-TEST-0  1
```

### show interfaces wireless detail

Use this command to view operational status and details wireless-specific information about all wireless interfaces.

```
vyos@vyos:~$ show interfaces wireless detail
wlan0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue state UP group default_
↳qlen 1000
    link/ether XX:XX:XX:XX:XX:c3 brd XX:XX:XX:XX:XX:ff
    inet xxx.xxx.99.254/24 scope global wlan0
        valid_lft forever preferred_lft forever
    inet6 fe80::xxxx:xxxx:fe54:2fc3/64 scope link
        valid_lft forever preferred_lft forever

    RX:  bytes    packets    errors    dropped    overrun    mcast
         66072      282         0         0         0         0
    TX:  bytes    packets    errors    dropped    carrier collisions
         83413      430         0         0         0         0

wlan1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue state UP group default_
↳qlen 1000
    link/ether XX:XX:XX:XX:XX:c3 brd XX:XX:XX:XX:XX:ff
    inet xxx.xxx.100.254/24 scope global wlan0
        valid_lft forever preferred_lft forever
    inet6 fe80::xxxx:xxxx:ffff:2ed3/64 scope link
        valid_lft forever preferred_lft forever

    RX:  bytes    packets    errors    dropped    overrun    mcast
         166072     5282         0         0         0         0
    TX:  bytes    packets    errors    dropped    carrier collisions
         183413     5430         0         0         0         0
```

### show interfaces wireless <wlanX>

This command shows both status and statistics on the specified wireless interface. The wireless interface identifier can range from wlan0 to wlan999.

```
vyos@vyos:~$ show interfaces wireless wlan0
wlan0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue state UP group default_
↳qlen 1000
    link/ether XX:XX:XX:XX:XX:c3 brd XX:XX:XX:XX:XX:ff
    inet xxx.xxx.99.254/24 scope global wlan0
        valid_lft forever preferred_lft forever
    inet6 fe80::xxxx:xxxx:fe54:2fc3/64 scope link
        valid_lft forever preferred_lft forever

    RX:  bytes    packets    errors    dropped    overrun    mcast
         66072      282         0         0         0         0

         83413      430         0         0         0         0
```

### show interfaces wireless <wlanX> brief

This command gives a brief status overview of a specified wireless interface. The wireless interface identifier can range from wlan0 to wlan999.

```
vyos@vyos:~$ show interfaces wireless wlan0 brief
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
-----
wlan0          192.168.2.254/24          u/u
-----
```

**show interfaces wireless <wlanX> queue**

Use this command to view wireless interface queue information. The wireless interface identifier can range from wlan0 to wlan999.

```
vyos@vyos:~$ show interfaces wireless wlan0 queue
qdisc pfifo_fast 0: root bands 3 priomap 1 2 2 2 1 2 0 0 1 1 1 1 1 1 1
Sent 810323 bytes 6016 pkt (dropped 0, overlimits 0 requeues 0)
rate 0bit 0pps backlog 0b 0p requeues 0
```

**show interfaces wireless <wlanX> scan**

This command is used to retrieve information about WAP within the range of your wireless interface. This command is useful on wireless interfaces configured in station mode.

**Bemerkung:** Scanning is not supported on all wireless drivers and wireless hardware. Refer to your driver and wireless hardware documentation for further details.

```
vyos@vyos:~$ show interfaces wireless wlan0 scan
Address          SSID          Channel  Signal (dbm)
00:53:3b:88:6e:d8 WLAN-576405    1        -64.00

00:53:3b:88:6e:d6 Telekom_FON    100       -72.00
00:53:3b:88:6e:d4 WLAN-576405    100       -71.00
00:53:44:a4:96:ec KabelBox-4DC8  56        -81.00
00:53:d9:7a:67:c2 WLAN-741980    1        -75.00
00:53:7c:99:ce:76 Vodafone Homespot 1        -86.00
00:53:44:a4:97:21 KabelBox-4DC8  1        -78.00
00:53:44:a4:97:21 Vodafone Hotspot 1        -79.00
00:53:44:a4:97:21 Vodafone Homespot 1        -79.00
00:53:86:40:30:da Telekom_FON    1        -86.00
00:53:7c:99:ce:76 Vodafone Hotspot 1        -86.00
00:53:44:46:d2:0b Vodafone Hotspot 1        -87.00
```

**Examples**

The following example creates a WAP. When configuring multiple WAP interfaces, you must specify unique IP addresses, channels, Network IDs commonly referred to as SSID (Service Set Identifier), and MAC addresses.

The WAP in this example has the following characteristics:

- IP address 192.168.2.1/24
- Network ID (SSID) TEST
- WPA passphrase 12345678
- Use 802.11n protocol
- Wireless channel 1

```

set interfaces wireless wlan0 address '192.168.2.1/24'
set interfaces wireless wlan0 type access-point
set interfaces wireless wlan0 channel 1
set interfaces wireless wlan0 mode n
set interfaces wireless wlan0 ssid 'TEST'
set interfaces wireless wlan0 security wpa mode wpa2
set interfaces wireless wlan0 security wpa cipher CCMP
set interfaces wireless wlan0 security wpa passphrase '12345678'
set interfaces wireless wlan0 country-code de

```

Resulting in

```

interfaces {
  [...]
  wireless wlan0 {
    address 192.168.2.1/24
    channel 1
    country-code de
    mode n
    security {
      wpa {
        cipher CCMP
        mode wpa2
        passphrase "12345678"
      }
    }
    ssid "TEST"
    type access-point
  }
}
system {
  [...]
  wifi-regulatory-domain DE
}

```

To get it to work as an access point with this configuration you will need to set up a DHCP server to work with that network. You can - of course - also bridge the Wireless interface with any configured bridge (*Bridge*) on the system.

## Intel AX200

The Intel AX200 card does not work out of the box in AP mode, see <https://unix.stackexchange.com/questions/598275/intel-ax200-ap-mode>. You can still put this card into AP mode using the following configuration:

```

set interfaces wireless wlan0 channel '1'
set interfaces wireless wlan0 country-code 'us'
set interfaces wireless wlan0 mode 'n'
set interfaces wireless wlan0 physical-device 'phy0'
set interfaces wireless wlan0 ssid 'VyOS'
set interfaces wireless wlan0 type 'access-point'

```

### 8.4.19 WWAN - Wireless Wide-Area-Network

The Wireless Wide-Area-Network interface provides access (through a wireless modem/wwan) to wireless networks provided by various cellular providers.

VyOS uses the *interfaces wwan* subsystem for configuration.

#### Configuration

##### Common interface configuration

**set interfaces wwan <interface> address <address | dhcp | dhcpv6>**

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

---

**Bemerkung:** When using DHCP to retrieve IPv4 address and if local customizations are needed, they should be possible using the enter and exit hooks provided. The hook dirs are:

- /config/scripts/dhcp-client/pre-hooks.d/
  - /config/scripts/dhcp-client/post-hooks.d/
- 

Example:

```
set interfaces wwan wwan0 address 192.0.2.1/24
set interfaces wwan wwan0 address 2001:db8::1/64
set interfaces wwan wwan0 address dhcp
set interfaces wwan wwan0 address dhcpv6
```

**set interfaces wwan <interface> description <description>**

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces wwan wwan0 description 'This is an awesome interface running on VyOS'
```

**set interfaces wwan <interface> disable**

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces wwan wwan0 disable
```

**set interfaces wwan <interface> disable-link-detect**

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces wwan wwan0 disable-link-detect
```

#### **set interfaces wwan <interface> mtu <mtu>**

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces wwan wwan0 mtu 1600
```

#### **set interfaces wwan <interface> ip adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally ,do not try to send me packets bigger than this value‘.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss <value>`

---

---

**Hinweis:** MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

#### **set interfaces wwan <interface> ip arp-cache-timeout**

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces wwan wwan0 ip arp-cache-timeout 180
```

#### **set interfaces wwan <interface> ip disable-arp-filter**

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces wwan wwan0 ip disable-arp-filter
```

#### **set interfaces wwan <interface> ip disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces wwan wwan0 ip disable-forwarding
```

**set interfaces wwan <interface> ip enable-directed-broadcast**

Define different modes for IP directed broadcast forwarding as described in [RFC 1812](#) and [RFC 2644](#).

If configured, incoming IP directed broadcast packets on this interface will be forwarded.

If this option is unset (default), incoming IP directed broadcast packets will not be forwarded.

```
set interfaces wwan wwan0 ip enable-directed-broadcast
```

**set interfaces wwan <interface> ip enable-arp-accept**

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces wwan wwan0 ip enable-arp-accept
```

**set interfaces wwan <interface> ip enable-arp-announce**

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces wwan wwan0 ip enable-arp-announce
```

**set interfaces wwan <interface> ip enable-arp-ignore**

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces wwan wwan0 ip enable-arp-ignore
```

**set interfaces wwan <interface> ip enable-proxy-arp**

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces wwan wwan0 ip enable-proxy-arp
```

**set interfaces wwan <interface> ip proxy-arp-pvlan**

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy\_arp'ing.

---

**Bemerkung:** Does not need to be used together with proxy\_arp.

---

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

**set interfaces wwan <interface> ip source-validation <strict | loose | disable>**

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

**set interfaces wwan <interface> ipv6 address autoconf**

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

---

**Bemerkung:** This method automatically disables IPv6 traffic forwarding on the interface in question.

---

Example:

```
set interfaces wwan wwan0 ipv6 address autoconf
```

**set interfaces wwan <interface> ipv6 address eui64 <prefix>**

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces wwan wwan0 ipv6 address eui64 2001:db8:beef::/64
```

**set interfaces wwan <interface> ipv6 address no-default-link-local**

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces wwan wwan0 ipv6 address no-default-link-local
```

### **set interfaces wwan <interface> ipv6 disable-forwarding**

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces wwan wwan0 ipv6 disable-forwarding
```

### **set interfaces wwan <interface> ipv6 adjust-mss <mss | clamp-mss-to-pmtu>**

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

---

**Bemerkung:** This command was introduced in VyOS 1.4 - it was previously called: `set firewall options interface <name> adjust-mss6 <value>`

---

---

**Hinweis:** MSS value = MTU - 40 (IPv6 header) - 20 (TCP header), resulting in 1432 bytes on a 1492 byte MTU.

---

Instead of a numerical MSS value *clamp-mss-to-pmtu* can be used to automatically set the proper value.

### **set interfaces wwan <interface> ipv6 accept-dad <1-3>**

Whether to accept DAD (Duplicate Address Detection).

- 0: Disable DAD
- 1: Enable DAD (default)
- 2: Enable DAD, and disable IPv6 operation if MAC-based duplicate link-local address has been found.

Example:

```
set interfaces wwan wwan0 ipv6 accept-dad 2
```

### **set interfaces wwan <interface> ipv6 dup-addr-detect-transmits <n>**

The amount of Duplicate Address Detection probes to send.

Default: 1

Example:

```
set interfaces wwan wwan0 ipv6 dup-addr-detect-transmits 5
```

### **set interfaces wwan <interface> vrf <vrf>**

Place interface in given VRF instance.

**Siehe auch:**

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces wwan wwan0 vrf red
```

## DHCP(v6)

**set interfaces wwan <interface> dhcp-options client-id <description>**

**RFC 2131** states: The client MAY choose to explicitly provide the identifier through the ,client identifier' option. If the client supplies a ,client identifier', the client MUST use the same ,client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces wwan wwan0 dhcp-options client-id 'foo-bar'
```

**set interfaces wwan <interface> dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces wwan wwan0 dhcp-options host-name 'VyOS'
```

**set interfaces wwan <interface> dhcp-options vendor-class-id <vendor-id>**

This option is used by some DHCP clients to identify the vendor type and possibly the configuration of a DHCP client. The information is a string of bytes whose contents are specific to the vendor and are not specified in a standard.

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces wwan wwan0 dhcp-options vendor-class-id 'VyOS'
```

**set interfaces wwan <interface> dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces wwan wwan0 dhcp-options no-default-route
```

**set interfaces wwan <interface> dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces wwan wwan0 dhcp-options default-route-distance 220
```

**set interfaces wwan <interface> dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces wwan wwan0 dhcp-options reject 192.168.100.0/24
```

**set interfaces wwan <interface> dhcp-options user-class <string>**

This option is used by some DHCP clients as a way for users to specify identifying information to the client. This can be used in a similar way to the vendor-class-identifier option, but the value of the option is specified by the user, not the vendor.

Example:

```
set interfaces wwan wwan0 dhcp-options user-class VyOS
```

**set interfaces wwan <interface> dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces wwan wwan0 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

**set interfaces wwan <interface> dhcpv6-options no-release**

When no-release is specified, dhcp6c will send a release message on client exit to prevent losing an assigned address or prefix.

```
set interfaces wwan wwan0 dhcpv6-options no-release
```

**set interfaces wwan <interface> dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces wwan wwan0 dhcpv6-options parameters-only
```

**set interfaces wwan <interface> dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces wwan wwan0 dhcpv6-options rapid-commit
```

**set interfaces wwan <interface> dhcpv6-options temporary**

Request only a temporary address and not form an IA\_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces wwan wwan0 dhcpv6-options temporary
```

**DHCPv6 Prefix Delegation (PD)**

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

**set interfaces wwan <interface> dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces wwan wwan0 dhcpv6-options pd 0 length 56
```

**set interfaces wwan <interface> dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces wwan wwan0 dhcpv6-options pd 0 interface eth8 address 65534
```

**set interfaces wwan <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:fff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:fff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces wwan wwan0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

## WirelessModem (WWAN) options

**set interfaces wwan <interface> apn <apn>**

Every WWAN connection requires an APN (Access Point Name) which is used by the client to dial into the ISPs network. This is a mandatory parameter. Contact your Service Provider for correct APN.

## Operation

**show interfaces wwan <interface>**

Show detailed information on given <interface>

```
vyos@vyos:~$ show interfaces wwan wwan0
wwan0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UNKNOWN
->group default qlen 1000

## Example

The following example is based on a Sierra Wireless MC7710 miniPCIe card (only the form factor in reality it runs USB) and Deutsche Telekom as ISP. The card is assembled into a *PC Engines APU4*.

```

set interfaces wwan wwan0 apn 'internet.telekom'
set interfaces wwan wwan0 address 'dhcp'

```

## Supported Modules

The following hardware modules have been tested successfully in an *PC Engines APU4* board:

- Sierra Wireless AirPrime MC7304 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7430 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7455 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7710 miniPCIe card (LTE)
- Huawei ME909u-521 miniPCIe card (LTE)
- Huawei ME909s-120 miniPCIe card (LTE)

## Firmware Update

All available WWAN cards have a build in, reprogrammable firmware. Most of the vendors provide a regular update to the firmware used in the baseband chip.

As VyOS makes use of the QMI interface to connect to the WWAN modem cards, also the firmware can be reprogrammed.

To update the firmware, VyOS also ships the *qmi-firmware-update* binary. To upgrade the firmware of an e.g. Sierra Wireless MC7710 module to the firmware provided in the file 9999999\_9999999\_9200\_03.05.14.00\_00\_generic\_000.000\_001\_SPKG\_MC.cwe use the following command:

```

$ sudo qmi-firmware-update --update -d 1199:68a2 \
  9999999_9999999_9200_03.05.14.00_00_generic_000.000_001_SPKG_MC.cwe

```

## 8.5 Load-balancing

### 8.5.1 WAN load balancing

Outbound traffic can be balanced between two or more outbound interfaces. If a path fails, traffic is balanced across the remaining healthy paths, a recovered path is automatically added back to the routing table and used by the load balancer. The load balancer automatically adds routes for each path to the routing table and balances traffic across the configured interfaces, determined by interface health and weight.

In a minimal configuration, the following must be provided:

- an interface with a nexthop
- one rule with a LAN (inbound-interface) and the WAN (interface).

Let's assume we have two DHCP WAN interfaces and one LAN (eth2):

```
set load-balancing wan interface-health eth0 nexthop 'dhcp'
set load-balancing wan interface-health eth1 nexthop 'dhcp'
set load-balancing wan rule 1 inbound-interface 'eth2'
set load-balancing wan rule 1 interface eth0
set load-balancing wan rule 1 interface eth1
```

**Bemerkung:** WAN Load Balancing should not be used when dynamic routing protocol is used/needed. This feature creates customized routing tables and firewall rules, that makes it incompatible to use with routing protocols.

### Balancing Rules

Interfaces, their weight and the type of traffic to be balanced are defined in numbered balancing rule sets. The rule sets are executed in numerical order against outgoing packets. In case of a match the packet is sent through an interface specified in the matching rule. If a packet doesn't match any rule it is sent by using the system routing table. Rule numbers can't be changed.

Create a load balancing rule, it can be a number between 1 and 9999:

```
vyos@vyos# set load-balancing wan rule 1
Possible completions:
description          Description for this rule
> destination        Destination
exclude              Exclude packets matching this rule from wan load balance
failover             Enable failover for packets matching this rule from wan load
↳ balance
inbound-interface    Inbound interface name (e.g., "eth0") [REQUIRED]
+> interface          Interface name [REQUIRED]
> limit              Enable packet limit for this rule
per-packet-balancing Option to match traffic per-packet instead of the default, per-
↳ flow
protocol             Protocol to match
> source             Source information
```

## Interface weight

Let's expand the example from above and add weight to the interfaces. The bandwidth from eth0 is larger than eth1. Per default, outbound traffic is distributed randomly across available interfaces. Weights can be assigned to interfaces to influence the balancing.

```
set load-balancing wan rule 1 interface eth0 weight 2
set load-balancing wan rule 1 interface eth1 weight 1
```

66% of traffic is routed to eth0, eth1 gets 33% of traffic.

## Rate limit

A packet rate limit can be set for a rule to apply the rule to traffic above or below a specified threshold. To configure the rate limiting use:

```
set load-balancing wan rule <rule> limit <parameter>
```

- **burst**: Number of packets allowed to overshoot the limit within period. Default 5.
- **period**: Time window for rate calculation. Possible values: **second** (one second), **minute** (one minute), **hour** (one hour). Default is **second**.
- **rate**: Number of packets. Default 5.
- **threshold**: below or above the specified rate limit.

## Flow and packet-based balancing

Outgoing traffic is balanced in a flow-based manner. A connection tracking table is used to track flows by their source address, destination address and port. Each flow is assigned to an interface according to the defined balancing rules and subsequent packets are sent through the same interface. This has the advantage that packets always arrive in order if links with different speeds are in use.

Packet-based balancing can lead to a better balance across interfaces when out of order packets are no issue. Per-packet-based balancing can be set for a balancing rule with:

```
set load-balancing wan rule <rule> per-packet-balancing
```

## Exclude traffic

To exclude traffic from load balancing, traffic matching an exclude rule is not balanced but routed through the system routing table instead:

```
set load-balancing wan rule <rule> exclude
```

## Health checks

The health of interfaces and paths assigned to the load balancer is periodically checked by sending ICMP packets (ping) to remote destinations, a TTL test or the execution of a user defined script. If an interface fails the health check it is removed from the load balancer's pool of interfaces. To enable health checking for an interface:

```
vyos@vyos# set load-balancing wan interface-health <interface>
Possible completions:
failure-count      Failure count
nexthop            Outbound interface nexthop address. Can be 'dhcp or ip address'
↪ [REQUIRED]
success-count      Success count
+> test           Rule number
```

Specify nexthop on the path to the destination, ipv4-address can be set to dhcp

```
set load-balancing wan interface-health <interface> nexthop <ipv4-address>
```

Set the number of health check failures before an interface is marked as unavailable, range for number is 1 to 10, default 1. Or set the number of successful health checks before an interface is added back to the interface pool, range for number is 1 to 10, default 1.

```
set load-balancing wan interface-health <interface> failure-count <number>
set load-balancing wan interface-health <interface> success-count <number>
```

Each health check is configured in its own test, tests are numbered and processed in numeric order. For multi target health checking multiple tests can be defined:

```
vyos@vyos# set load-balancing wan interface-health eth1 test 0
Possible completions:
resp-time          Ping response time (seconds)
target             Health target address
test-script        Path to user defined script
ttl-limit          Ttl limit (hop count)
type              WLB test type
```

- **resp-time**: the maximum response time for ping in seconds. Range 1...30, default 5
- **target**: the target to be sent ICMP packets to, address can be an IPv4 address or hostname
- **test-script**: A user defined script must return 0 to be considered successful and non-zero to fail. Scripts are located in /config/scripts, for different locations the full path needs to be provided
- **ttl-limit**: For the UDP TTL limit test the hop count limit must be specified. The limit must be shorter than the path length, an ICMP time expired message is needed to be returned for a successful test. default 1
- **type**: Specify the type of test. type can be ping, ttl or a user defined script

## Source NAT rules

Per default, interfaces used in a load balancing pool replace the source IP of each outgoing packet with its own address to ensure that replies arrive on the same interface. This works through automatically generated source NAT (SNAT) rules, these rules are only applied to balanced traffic. In cases where this behaviour is not desired, the automatic generation of SNAT rules can be disabled:

```
set load-balancing wan disable-source-nat
```

## Sticky Connections

Inbound connections to a WAN interface can be improperly handled when the reply is sent back to the client.

Upon reception of an incoming packet, when a response is sent, it might be desired to ensure that it leaves from the same interface as the inbound one. This can be achieved by enabling sticky connections in the load balancing:

```
set load-balancing wan sticky-connections inbound
```

## Failover

In failover mode, one interface is set to be the primary interface and other interfaces are secondary or spare. Instead of balancing traffic across all healthy interfaces, only the primary interface is used and in case of failure, a secondary interface selected from the pool of available interfaces takes over. The primary interface is selected based on its weight and health, others become secondary interfaces. Secondary interfaces to take over a failed primary interface are chosen from the load balancer's interface pool, depending on their weight and health. Interface roles can also be selected based on rule order by including interfaces in balancing rules and ordering those rules accordingly. To put the load balancer in failover mode, create a failover rule:

```
set load-balancing wan rule <number> failover
```

Because existing sessions do not automatically fail over to a new path, the session table can be flushed on each connection state change:

```
set load-balancing wan flush-connections
```

**Warnung:** Flushing the session table will cause other connections to fall back from flow-based to packet-based balancing until each flow is reestablished.

## Script execution

A script can be run when an interface state change occurs. Scripts are run from /config/scripts, for a different location specify the full path:

```
set load-balancing wan hook script-name
```

Two environment variables are available:

- WLB\_INTERFACE\_NAME=[interfacename]: Interface to be monitored
- WLB\_INTERFACE\_STATE=[ACTIVE|FAILED]: Interface state

**Warnung:** Blocking call with no timeout. System will become unresponsive if script does not return!

## Handling and monitoring

Show WAN load balancer information including test types and targets. A character at the start of each line depicts the state of the test

- + successful
- - failed
- a blank indicates that no test has been carried out

```
vyos@vyos:~$ show wan-load-balance
Interface: eth0
Status: failed
Last Status Change: Tue Jun 11 20:12:19 2019
-Test: ping Target:
    Last Interface Success: 55s
    Last Interface Failure: 0s
    # Interface Failure(s): 5

Interface: eth1
Status: active
Last Status Change: Tue Jun 11 20:06:42 2019
+Test: ping Target:
    Last Interface Success: 0s
    Last Interface Failure: 6m26s
    # Interface Failure(s): 0
```

Show connection data of load balanced traffic:

```
vyos@vyos:~$ show wan-load-balance connection
conntrack v1.4.2 (conntrack-tools): 3 flow entries have been shown.
Type      State      Src              Dst              Packets Bytes

↪168.188.71
```

## Restart

```
restart wan-load-balance
```

## 8.5.2 Reverse-proxy

VyOS reverse-proxy is balancer and proxy server that provides high-availability, load balancing and proxying for TCP (level 4) and HTTP-based (level 7) applications.

### Configuration

Service configuration is responsible for binding to a specific port, while the backend configuration determines the type of load balancing to be applied and specifies the real servers to be utilized.

### Service

```
set load-balancing reverse-proxy service <name> listen-address <address>
```

Set service to bind on IP address, by default listen on any IPv4 and IPv6

```
set load-balancing reverse-proxy service <name> port <port>
```

Create service <name> to listen on <port>

```
set load-balancing reverse-proxy service <name> mode <tcp|http>
```

Configure service <name> mode TCP or HTTP

```
set load-balancing reverse-proxy service <name> backend <name>
```

Configure service <name> to use the backend <name>

```
set load-balancing reverse-proxy service <name> ssl certificate <name>
```

Set SSL certificate <name> for service <name>

## Rules

Rules allow to control and route incoming traffic to specific backend based on predefined conditions. Rules allow to define matching criteria and perform action accordingly.

**set load-balancing reverse-proxy service <name> rule <rule> domain-name <name>**

Match domain name

**set load-balancing reverse-proxy service <name> rule <rule> ssl <sni>**

**SSL match Server Name Indication (SNI) option:**

- req-ssl-sni SSL Server Name Indication (SNI) request match
- ssl-fc-sni SSL frontend connection Server Name Indication match
- ssl-fc-sni-end SSL frontend match end of connection Server Name

Indication

**set load-balancing reverse-proxy service <name> rule <rule> url-path <match> <url>**

Allows to define URL path matching rules for a specific service.

With this command, you can specify how the URL path should be matched against incoming requests.

**The available options for <match> are:**

- begin Matches the beginning of the URL path
- end Matches the end of the URL path.
- exact Requires an exactly match of the URL path

**set load-balancing reverse-proxy service <name> rule <rule> set backend <name>**

Assign a specific backend to a rule

**set load-balancing reverse-proxy service <name> rule <rule> redirect-location <url>**

Redirect URL to a new location

## Backend

**set load-balancing reverse-proxy backend <name> balance <balance>**

Load-balancing algorithms to be used for distributed requests among the available servers

**Balance algorithms:**

- source-address Distributes requests based on the source IP address of the client
- round-robin Distributes requests in a circular manner, sequentially sending each request to the next server in line
- least-connection Distributes requests to the server with the fewest active connections

**set load-balancing reverse-proxy backend <name> mode <mode>**

Configure backend <name> mode TCP or HTTP

**set load-balancing reverse-proxy backend <name> parameters http-check**

Enable layer 7 HTTP health check

**set load-balancing reverse-proxy backend <name> server <name> address <x.x.x.x>**

Set the address of the backend server to which the incoming traffic will be forwarded

```
set load-balancing reverse-proxy backend <name> server <name> port <port>
```

Set the address of the backend port

```
set load-balancing reverse-proxy backend <name> server <name> check
```

Active health check backend server

```
set load-balancing reverse-proxy backend <name> server <name> send-proxy
```

Send a Proxy Protocol version 1 header (text format)

```
set load-balancing reverse-proxy backend <name> server <name> send-proxy-v2
```

Send a Proxy Protocol version 2 header (binary format)

```
set load-balancing reverse-proxy backend <name> ssl ca-certificate <ca-certificate>
```

Configure requests to the backend server to use SSL encryption and authenticate backend against <ca-certificate>

```
set load-balancing reverse-proxy backend <name> ssl no-verify
```

Configure requests to the backend server to use SSL encryption without validating server certificate

## HTTP health check

For web application providing information about their state HTTP health checks can be used to determine their availability.

```
set load-balancing reverse-proxy backend <name> http-check
```

Enables HTTP health checks using OPTION HTTP requests against ,/‘ and expecting a successful response code in the 200-399 range.

```
set load-balancing reverse-proxy backend <name> http-check method <method>
```

Sets the HTTP method to be used, can be either: option, get, post, put

```
set load-balancing reverse-proxy backend <name> http-check uri <path>
```

Sets the endpoint to be used for health checks

```
set load-balancing reverse-proxy backend <name> http-check expect <condition>
```

Sets the expected result condition for considering a server healthy. Some possible examples are:

- **status 200** Expecting a 200 response code
- **status 200-399** Expecting a non-failure response code
- **string success** Expecting the string *success* in the response body

## Global

Global parameters

```
set load-balancing reverse-proxy global-parameters max-connections <num>
```

Limit maximum number of connections

```
set load-balancing reverse-proxy global-parameters ssl-bind-ciphers <ciphers>
```

Limit allowed cipher algorithms used during SSL/TLS handshake

```
set load-balancing reverse-proxy global-parameters tls-version-min <version>
```

Specify the minimum required TLS version 1.2 or 1.3

## Redirect HTTP to HTTPS

Configure the load-balancing reverse-proxy service for HTTP.

This configuration listen on port 80 and redirect incoming requests to HTTPS:

```
set load-balancing reverse-proxy service http port '80'
set load-balancing reverse-proxy service http redirect-http-to-https
```

The name of the service can be different, in this example it is only for convenience.

## Examples

### Level 4 balancing

This configuration enables the TCP reverse proxy for the „my-tcp-api“ service. Incoming TCP connections on port 8888 will be load balanced across the backend servers (srv01 and srv02) using the round-robin load-balancing algorithm.

```
set load-balancing reverse-proxy service my-tcp-api backend 'bk-01'
set load-balancing reverse-proxy service my-tcp-api mode 'tcp'
set load-balancing reverse-proxy service my-tcp-api port '8888'

set load-balancing reverse-proxy backend bk-01 balance 'round-robin'
set load-balancing reverse-proxy backend bk-01 mode 'tcp'

set load-balancing reverse-proxy backend bk-01 server srv01 address '192.0.2.11'
set load-balancing reverse-proxy backend bk-01 server srv01 port '8881'
set load-balancing reverse-proxy backend bk-01 server srv02 address '192.0.2.12'
set load-balancing reverse-proxy backend bk-01 server srv02 port '8882'
```

## Balancing based on domain name

The following configuration demonstrates how to use VyOS to achieve load balancing based on the domain name.

The HTTP service listen on TCP port 80.

Rule 10 matches requests with the domain name `node1.example.com` forwards to the backend `bk-api-01`

Rule 20 matches requests with the domain name `node2.example.com` forwards to the backend `bk-api-02`

```
set load-balancing reverse-proxy service http description 'bind app listen on 443 port'
set load-balancing reverse-proxy service http mode 'tcp'
set load-balancing reverse-proxy service http port '80'

set load-balancing reverse-proxy service http rule 10 domain-name 'node1.example.com'
set load-balancing reverse-proxy service http rule 10 set backend 'bk-api-01'
set load-balancing reverse-proxy service http rule 20 domain-name 'node2.example.com'
set load-balancing reverse-proxy service http rule 20 set backend 'bk-api-02'

set load-balancing reverse-proxy backend bk-api-01 description 'My API-1'
set load-balancing reverse-proxy backend bk-api-01 mode 'tcp'
set load-balancing reverse-proxy backend bk-api-01 server api01 address '127.0.0.1'
set load-balancing reverse-proxy backend bk-api-01 server api01 port '4431'
set load-balancing reverse-proxy backend bk-api-02 description 'My API-2'
set load-balancing reverse-proxy backend bk-api-02 mode 'tcp'
set load-balancing reverse-proxy backend bk-api-02 server api01 address '127.0.0.2'
set load-balancing reverse-proxy backend bk-api-02 server api01 port '4432'
```

## Terminate SSL

The following configuration terminates SSL on the router.

The `http` service is listens on port 80 and force redirects from HTTP to HTTPS.

The `https` service listens on port 443 with backend `bk-default` to handle HTTPS traffic. It uses certificate named `cert` for SSL termination.

Rule 10 matches requests with the exact URL path `/.well-known/xxx` and redirects to location `/certs/`.

Rule 20 matches requests with URL paths ending in `/mail` or exact path `/email/bar` redirect to location `/postfix/`.

Additional global parameters are set, including the maximum number connection limit of 4000 and a minimum TLS version of 1.3.

```
set load-balancing reverse-proxy service http description 'Force redirect to HTTPS'
set load-balancing reverse-proxy service http port '80'
set load-balancing reverse-proxy service http redirect-http-to-https

set load-balancing reverse-proxy service https backend 'bk-default'
set load-balancing reverse-proxy service https description 'listen on 443 port'
set load-balancing reverse-proxy service https mode 'http'
set load-balancing reverse-proxy service https port '443'
set load-balancing reverse-proxy service https ssl certificate 'cert'

set load-balancing reverse-proxy service https rule 10 url-path exact '/.well-known/xxx'
set load-balancing reverse-proxy service https rule 10 set redirect-location '/certs/'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set load-balancing reverse-proxy service https rule 20 url-path end '/mail'
set load-balancing reverse-proxy service https rule 20 url-path exact '/email/bar'
set load-balancing reverse-proxy service https rule 20 set redirect-location '/postfix/'

set load-balancing reverse-proxy backend bk-default description 'Default backend'
set load-balancing reverse-proxy backend bk-default mode 'http'
set load-balancing reverse-proxy backend bk-default server sr01 address '192.0.2.23'
set load-balancing reverse-proxy backend bk-default server sr01 port '80'

set load-balancing reverse-proxy global-parameters max-connections '4000'
set load-balancing reverse-proxy global-parameters tls-version-min '1.3'

```

## SSL Bridging

The following configuration terminates incoming HTTPS traffic on the router, then re-encrypts the traffic and sends to the backend server via HTTPS. This is useful if encryption is required for both legs, but you do not want to install publicly trusted certificates on each backend server.

Backend service certificates are checked against the certificate authority specified in the configuration, which could be an internal CA.

The https service listens on port 443 with backend bk-bridge-ssl to handle HTTPS traffic. It uses certificate named cert for SSL termination.

The bk-bridge-ssl backend connects to sr01 server on port 443 via HTTPS and checks backend server has a valid certificate trusted by CA cacert

```

set load-balancing reverse-proxy service https backend 'bk-bridge-ssl'
set load-balancing reverse-proxy service https description 'listen on 443 port'
set load-balancing reverse-proxy service https mode 'http'
set load-balancing reverse-proxy service https port '443'
set load-balancing reverse-proxy service https ssl certificate 'cert'

set load-balancing reverse-proxy backend bk-bridge-ssl description 'SSL backend'
set load-balancing reverse-proxy backend bk-bridge-ssl mode 'http'
set load-balancing reverse-proxy backend bk-bridge-ssl ssl ca-certificate 'cacert'
set load-balancing reverse-proxy backend bk-bridge-ssl server sr01 address '192.0.2.23'
set load-balancing reverse-proxy backend bk-bridge-ssl server sr01 port '443'

```

## Balancing with HTTP health checks

This configuration enables HTTP health checks on backend servers.

```

set load-balancing reverse-proxy service my-tcp-api backend 'bk-01'
set load-balancing reverse-proxy service my-tcp-api mode 'tcp'
set load-balancing reverse-proxy service my-tcp-api port '8888'

set load-balancing reverse-proxy backend bk-01 balance 'round-robin'
set load-balancing reverse-proxy backend bk-01 mode 'tcp'

set load-balancing reverse-proxy backend bk-01 http-check method 'get'

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set load-balancing reverse-proxy backend bk-01 http-check uri '/health'
set load-balancing reverse-proxy backend bk-01 http-check expect 'status 200'

set load-balancing reverse-proxy backend bk-01 server srv01 address '192.0.2.11'
set load-balancing reverse-proxy backend bk-01 server srv01 port '8881'
set load-balancing reverse-proxy backend bk-01 server srv01 check
set load-balancing reverse-proxy backend bk-01 server srv02 address '192.0.2.12'
set load-balancing reverse-proxy backend bk-01 server srv02 port '8882'
set load-balancing reverse-proxy backend bk-01 server srv02 check

```

## 8.6 NAT

### 8.6.1 NAT44

NAT (Network Address Translation) is a common method of remapping one IP address space into another by modifying network address information in the IP header of packets while they are in transit across a traffic routing device. The technique was originally used as a shortcut to avoid the need to readdress every host when a network was moved. It has become a popular and essential tool in conserving global address space in the face of IPv4 address exhaustion. One Internet-routable IP address of a NAT gateway can be used for an entire private network.

IP masquerading is a technique that hides an entire IP address space, usually consisting of private IP addresses, behind a single IP address in another, usually public address space. The hidden addresses are changed into a single (public) IP address as the source address of the outgoing IP packets so they appear as originating not from the hidden host but from the routing device itself. Because of the popularity of this technique to conserve IPv4 address space, the term NAT has become virtually synonymous with IP masquerading.

As network address translation modifies the IP address information in packets, NAT implementations may vary in their specific behavior in various addressing cases and their effect on network traffic. The specifics of NAT behavior are not commonly documented by vendors of equipment containing NAT implementations.

The computers on an internal network can use any of the addresses set aside by the IANA (Internet Assigned Numbers Authority) for private addressing (see [RFC 1918](#)). These reserved IP addresses are not in use on the Internet, so an external machine will not directly route to them. The following addresses are reserved for private use:

- 10.0.0.0 to 10.255.255.255 (CIDR: 10.0.0.0/8)
- 172.16.0.0 to 172.31.255.255 (CIDR: 172.16.0.0/12)
- 192.168.0.0 to 192.168.255.255 (CIDR: 192.168.0.0/16)

If an ISP deploys a CGN (Carrier-grade NAT), and uses [RFC 1918](#) address space to number customer gateways, the risk of address collision, and therefore routing failures, arises when the customer network already uses an [RFC 1918](#) address space.

This prompted some ISPs to develop a policy within the ARIN (American Registry for Internet Numbers) to allocate new private address space for CGNs, but ARIN deferred to the IETF before implementing the policy indicating that the matter was not a typical allocation issue but a reservation of addresses for technical purposes (per [RFC 2860](#)).

IETF published [RFC 6598](#), detailing a shared address space for use in ISP CGN deployments that can handle the same network prefixes occurring both on inbound and outbound interfaces. ARIN returned address space to the IANA for this allocation.

The allocated address block is 100.64.0.0/10.

Devices evaluating whether an IPv4 address is public must be updated to recognize the new address space. Allocating more private IPv4 address space for NAT devices might prolong the transition to IPv6.

## Overview

### Different NAT Types

#### SNAT

SNAT (Source Network Address Translation) is the most common form of NAT and is typically referred to simply as NAT. To be more correct, what most people refer to as NAT is actually the process of PAT (Port Address Translation), or NAT overload. SNAT is typically used by internal users/private hosts to access the Internet - the source address is translated and thus kept private.

#### DNAT

DNAT (Destination Network Address Translation) changes the destination address of packets passing through the router, while *SNAT* changes the source address of packets. DNAT is typically used when an external (public) host needs to initiate a session with an internal (private) host. A customer needs to access a private service behind the routers public IP. A connection is established with the routers public IP address on a well known port and thus all traffic for this port is rewritten to address the internal (private) host.

#### Bidirectional NAT

This is a common scenario where both *SNAT* and *DNAT* are configured at the same time. It's commonly used when internal (private) hosts need to establish a connection with external resources and external systems need to access internal (private) resources.

### NAT, Routing, Firewall Interaction

There is a very nice picture/explanation in the Vyatta documentation which should be rewritten here.

#### NAT Ruleset

NAT is configured entirely on a series of so called *rules*. Rules are numbered and evaluated by the underlying OS in numerical order! The rule numbers can be changed by utilizing the `rename` and `copy` commands.

---

**Bemerkung:** Changes to the NAT system only affect newly established connections. Already established connections are not affected.

---

---

**Hinweis:** When designing your NAT ruleset leave some space between consecutive rules for later extension. Your ruleset could start with numbers 10, 20, 30. You thus can later extend the ruleset and place new rules between existing ones.

---

Rules will be created for both *SNAT* and *DNAT*.

For *Bidirectional NAT* a rule for both *SNAT* and *DNAT* needs to be created.

## Traffic Filters

Traffic Filters are used to control which packets will have the defined NAT rules applied. Five different filters can be applied within a NAT rule.

- **outbound-interface** - applicable only to *SNAT*. It configures the interface which is used for the outside traffic that this translation rule applies to. Interface groups, inverted selection and wildcard, are also supported.

Examples:

```
set nat source rule 20 outbound-interface name eth0
set nat source rule 30 outbound-interface name bond1*
set nat source rule 20 outbound-interface name !vtun2
set nat source rule 20 outbound-interface group GROUP1
set nat source rule 20 outbound-interface group !GROUP2
```

- **inbound-interface** - applicable only to *DNAT*. It configures the interface which is used for the inside traffic the translation rule applies to. Interface groups, inverted selection and wildcard, are also supported.

Example:

```
set nat destination rule 20 inbound-interface name eth0
set nat destination rule 30 inbound-interface name bond1*
set nat destination rule 20 inbound-interface name !vtun2
set nat destination rule 20 inbound-interface group GROUP1
set nat destination rule 20 inbound-interface group !GROUP2
```

- **protocol** - specify which types of protocols this translation rule applies to. Only packets matching the specified protocol are NATed. By default this applies to *all* protocols.

Example:

- Set SNAT rule 20 to only NAT TCP and UDP packets
- Set DNAT rule 20 to only NAT UDP packets

```
set nat source rule 20 protocol tcp_udp
set nat destination rule 20 protocol udp
```

- **source** - specifies which packets the NAT translation rule applies to based on the packets source IP address and/or source port. Only matching packets are considered for NAT.

Example:

- Set SNAT rule 20 to only NAT packets arriving from the 192.0.2.0/24 network
- Set SNAT rule 30 to only NAT packets arriving from the 203.0.113.0/24 network with a source port of 80 and 443

```
set nat source rule 20 source address 192.0.2.0/24
set nat source rule 30 source address 203.0.113.0/24
set nat source rule 30 source port 80,443
```

- **destination** - specify which packets the translation will be applied to, only based on the destination address and/or port number configured.

---

**Bemerkung:** If no destination is specified the rule will match on any destination address and port.

---

Example:

- Configure SNAT rule (40) to only NAT packets with a destination address of 192.0.2.1.

```
set nat source rule 40 destination address 192.0.2.1
```

## Address Conversion

Every NAT rule has a translation command defined. The address defined for the translation is the address used when the address information in a packet is replaced.

### Source Address

For *SNAT* rules the packets source address will be replaced with the address specified in the translation command. A port translation can also be specified and is part of the translation address.

---

**Bemerkung:** The translation address must be set to one of the available addresses on the configured *outbound-interface* or it must be set to *masquerade* which will use the primary IP address of the *outbound-interface* as its translation address.

---

---

**Bemerkung:** When using NAT for a large number of host systems it recommended that a minimum of 1 IP address is used to NAT every 256 private host systems. This is due to the limit of 65,000 port numbers available for unique translations and a reserving an average of 200-300 sessions per host system.

---

Example:

- Define a discrete source IP address of 100.64.0.1 for SNAT rule 20
- Use address *masquerade* (the interfaces primary address) on rule 30
- For a large amount of private machines behind the NAT your address pool might to be bigger. Use any address in the range 100.64.0.10 - 100.64.0.20 on SNAT rule 40 when doing the translation

```
set nat source rule 20 translation address 100.64.0.1
set nat source rule 30 translation address 'masquerade'
set nat source rule 40 translation address 100.64.0.10-100.64.0.20
```

### Destination Address

For *DNAT* rules the packets destination address will be replaced by the specified address in the *translation address* command.

Example:

- DNAT rule 10 replaces the destination address of an inbound packet with 192.0.2.10

```
set nat destination rule 10 translation address 192.0.2.10
```

Also, in *DNAT*, redirection to localhost is supported. The redirect statement is a special form of dn timer which always translates the destination address to the local host's one.

Example of redirection:

```
set nat destination rule 10 translation redirect port 22
```

## NAT Load Balance

Advanced configuration can be used in order to apply source or destination NAT, and within a single rule, be able to define multiple translated addresses, so NAT balances the translations among them.

NAT Load Balance uses an algorithm that generates a hash and based on it, then it applies corresponding translation. This hash can be generated randomly, or can use data from the ip header: source-address, destination-address, source-port and/or destination-port. By default, it will generate the hash randomly.

When defining the translated address, called **backends**, a **weight** must be configured. This lets the user define load balance distribution according to their needs. The sum of all the weights defined for the backends should be equal to 100. In other words, the weight defined for the backend is the percentage of the connections that will receive such backend.

```
set nat [source | destination] rule <rule> load-balance hash [source-address |
destination-address | source-port | destination-port | random]
set nat [source | destination] rule <rule> load-balance backend <x.x.x.x> weight <1-100>
```

## Configuration Examples

To setup SNAT, we need to know:

- The internal IP addresses we want to translate
- The outgoing interface to perform the translation on
- The external IP address to translate to

In the example used for the Quick Start configuration above, we demonstrate the following configuration:

```
set nat source rule 100 outbound-interface name 'eth0'
set nat source rule 100 source address '192.168.0.0/24'
set nat source rule 100 translation address 'masquerade'
```

Which generates the following configuration:

```
rule 100 {
    outbound-interface {
        name eth0
    }
    source {
        address 192.168.0.0/24
    }
    translation {
        address masquerade
    }
}
```

In this example, we use **masquerade** as the translation address instead of an IP address. The **masquerade** target is effectively an alias to say „use whatever IP address is on the outgoing interface“, rather than a statically configured IP address. This is useful if you use DHCP for your outgoing interface and do not know what the external address will be.

When using NAT for a large number of host systems it is recommended that a minimum of 1 IP address is used to NAT every 256 host systems. This is due to the limit of 65,000 port numbers available for unique translations and a reserving an average of 200-300 sessions per host system.

Example: For an ~8,000 host network a source NAT pool of 32 IP addresses is recommended.

A pool of addresses can be defined by using a hyphen between two IP addresses:

```
set nat source rule 100 translation address '203.0.113.32-203.0.113.63'
```

## Avoiding „leaky“ NAT

Linux netfilter will not NAT traffic marked as INVALID. This often confuses people into thinking that Linux (or specifically VyOS) has a broken NAT implementation because non-NATed traffic is seen leaving an external interface. This is actually working as intended, and a packet capture of the „leaky“ traffic should reveal that the traffic is either an additional TCP „RST“, „FIN,ACK“, or „RST,ACK“ sent by client systems after Linux netfilter considers the connection closed. The most common is the additional TCP RST some host implementations send after terminating a connection (which is implementation-specific).

In other words, connection tracking has already observed the connection be closed and has transition the flow to INVALID to prevent attacks from attempting to reuse the connection.

You can avoid the „leaky“ behavior by using a firewall policy that drops „invalid“ state packets.

Having control over the matching of INVALID state traffic, e.g. the ability to selectively log, is an important troubleshooting tool for observing broken protocol behavior. For this reason, VyOS does not globally drop invalid state traffic, instead allowing the operator to make the determination on how the traffic is handled.

## Hairpin NAT/NAT Reflection

A typical problem with using NAT and hosting public servers is the ability for internal systems to reach an internal server using its external IP address. The solution to this is usually the use of split-DNS to correctly point host systems to the internal address when requests are made internally. Because many smaller networks lack DNS infrastructure, a work-around is commonly deployed to facilitate the traffic by NATing the request from internal hosts to the source address of the internal interface on the firewall.

This technique is commonly referred to as NAT Reflection or Hairpin NAT.

Example:

- Redirect Microsoft RDP traffic from the outside (WAN, external) world via *DNAT* in rule 100 to the internal, private host 192.0.2.40.
- Redirect Microsoft RDP traffic from the internal (LAN, private) network via *DNAT* in rule 110 to the internal, private host 192.0.2.40. We also need a *SNAT* rule 110 for the reverse path of the traffic. The internal network 192.0.2.0/24 is reachable via interface *eth0.10*.

```
set nat destination rule 100 description 'Regular destination NAT from external'
set nat destination rule 100 destination port '3389'
set nat destination rule 100 inbound-interface name 'pppoe0'
set nat destination rule 100 protocol 'tcp'
set nat destination rule 100 translation address '192.0.2.40'

set nat destination rule 110 description 'NAT Reflection: INSIDE'
set nat destination rule 110 destination port '3389'
set nat destination rule 110 inbound-interface name 'eth0.10'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set nat destination rule 110 protocol 'tcp'
set nat destination rule 110 translation address '192.0.2.40'

set nat source rule 110 description 'NAT Reflection: INSIDE'
set nat source rule 110 destination address '192.0.2.0/24'
set nat source rule 110 outbound-interface name 'eth0.10'
set nat source rule 110 protocol 'tcp'
set nat source rule 110 source address '192.0.2.0/24'
set nat source rule 110 translation address 'masquerade'

```

Which results in a configuration of:

```

vyos@vyos# show nat
destination {
  rule 100 {
    description "Regular destination NAT from external"
    destination {
      port 3389
    }
    inbound-interface {
      name pppoe0
    }
    protocol tcp
    translation {
      address 192.0.2.40
    }
  }
  rule 110 {
    description "NAT Reflection: INSIDE"
    destination {
      port 3389
    }
    inbound-interface {
      name eth0.10
    }
    protocol tcp
    translation {
      address 192.0.2.40
    }
  }
}
source {
  rule 110 {
    description "NAT Reflection: INSIDE"
    destination {
      address 192.0.2.0/24
    }
    outbound-interface {
      name eth0.10
    }
    protocol tcp
    source {

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

        address 192.0.2.0/24
    }
    translation {
        address masquerade
    }
}

```

## Destination NAT

DNAT is typically referred to as a **Port Forward**. When using VyOS as a NAT router and firewall, a common configuration task is to redirect incoming traffic to a system behind the firewall.

In this example, we will be using the example Quick Start configuration above as a starting point.

To setup a destination NAT rule we need to gather:

- The interface traffic will be coming in on;
- The protocol and port we wish to forward;
- The IP address of the internal system we wish to forward traffic to.

In our example, we will be forwarding web server traffic to an internal web server on 192.168.0.100. HTTP traffic makes use of the TCP protocol on port 80. For other common port numbers, see: [https://en.wikipedia.org/wiki/List\\_of\\_TCP\\_and\\_UDP\\_port\\_numbers](https://en.wikipedia.org/wiki/List_of_TCP_and_UDP_port_numbers)

Our configuration commands would be:

```

set nat destination rule 10 description 'Port Forward: HTTP to 192.168.0.100'
set nat destination rule 10 destination port '80'
set nat destination rule 10 inbound-interface name 'eth0'
set nat destination rule 10 protocol 'tcp'
set nat destination rule 10 translation address '192.168.0.100'

```

Which would generate the following NAT destination configuration:

```

nat {
    destination {
        rule 10 {
            description "Port Forward: HTTP to 192.168.0.100"
            destination {
                port 80
            }
            inbound-interface {
                name eth0
            }
            protocol tcp
            translation {
                address 192.168.0.100
            }
        }
    }
}

```

---

**Bemerkung:** If forwarding traffic to a different port than it is arriving on, you may also configure the translation port using *set nat destination rule [n] translation port*.

---

This establishes our Port Forward rule, but if we created a firewall policy it will likely block the traffic.

## Firewall rules for Destination NAT

It is important to note that when creating firewall rules, the DNAT translation occurs **before** traffic traverses the firewall. In other words, the destination address has already been translated to 192.168.0.100.

So in our firewall ruleset, we want to allow traffic which previously matched a destination nat rule. In order to avoid creating many rules, one for each destination nat rule, we can accept all **,dnat'** connections with one simple rule, using **connection-status** matcher:

```
set firewall ipv4 forward filter rule 10 action accept
set firewall ipv4 forward filter rule 10 connection-status nat destination
set firewall ipv4 forward filter rule 10 state new enable
```

This would generate the following configuration:

```
ipv4 {
  forward {
    filter {
      rule 10 {
        action accept
        connection-status {
          nat destination
        }
        state {
          new enable
        }
      }
    }
  }
}
```

## 1-to-1 NAT

Another term often used for DNAT is **1-to-1 NAT**. For a 1-to-1 NAT configuration, both DNAT and SNAT are used to NAT all traffic from an external IP address to an internal IP address and vice-versa.

Typically, a 1-to-1 NAT rule omits the destination port (all ports) and replaces the protocol with either **all** or **ip**.

Then a corresponding SNAT rule is created to NAT outgoing traffic for the internal IP to a reserved external IP. This dedicates an external IP address to an internal IP address and is useful for protocols which don't have the notion of ports, such as GRE.

Here's an extract of a simple 1-to-1 NAT configuration with one internal and one external interface:

```
set interfaces ethernet eth0 address '192.168.1.1/24'
set interfaces ethernet eth0 description 'Inside interface'
set interfaces ethernet eth1 address '192.0.2.30/24'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set interfaces ethernet eth1 description 'Outside interface'
set nat destination rule 2000 description '1-to-1 NAT example'
set nat destination rule 2000 destination address '192.0.2.30'
set nat destination rule 2000 inbound-interface name 'eth1'
set nat destination rule 2000 translation address '192.168.1.10'
set nat source rule 2000 description '1-to-1 NAT example'
set nat source rule 2000 outbound-interface name 'eth1'
set nat source rule 2000 source address '192.168.1.10'
set nat source rule 2000 translation address '192.0.2.30'

```

Firewall rules are written as normal, using the internal IP address as the source of outbound rules and the destination of inbound rules.

## NAT before VPN

Some application service providers (ASPs) operate a VPN gateway to provide access to their internal resources, and require that a connecting organisation translate all traffic to the service provider network to a source address provided by the ASP.

## Load Balance

Here we provide two examples on how to apply NAT Load Balance.

First scenario: apply destination NAT for all HTTP traffic coming through interface eth0, and use 4 backends. First backend should receive 30% of the request, second backend should get 20%, third 15% and the fourth 35%. We will use source and destination address for hash generation.

```

set nat destination rule 10 inbound-interface name eth0
set nat destination rule 10 protocol tcp
set nat destination rule 10 destination port 80
set nat destination rule 10 load-balance hash source-address
set nat destination rule 10 load-balance hash destination-address
set nat destination rule 10 load-balance backend 198.51.100.101 weight 30
set nat destination rule 10 load-balance backend 198.51.100.102 weight 20
set nat destination rule 10 load-balance backend 198.51.100.103 weight 15
set nat destination rule 10 load-balance backend 198.51.100.104 weight 35

```

Second scenario: apply source NAT for all outgoing connections from LAN 10.0.0.0/8, using 3 public addresses and equal distribution. We will generate the hash randomly.

```

set nat source rule 10 outbound-interface name eth0
set nat source rule 10 source address 10.0.0.0/8
set nat source rule 10 load-balance hash random
set nat source rule 10 load-balance backend 192.0.2.251 weight 33
set nat source rule 10 load-balance backend 192.0.2.252 weight 33
set nat source rule 10 load-balance backend 192.0.2.253 weight 34

```

## Example Network

Here's one example of a network environment for an ASP. The ASP requests that all connections from this company should come from 172.29.41.89 - an address that is assigned by the ASP and not in use at the customer site.

Abb. 1: NAT before VPN Topology

## Configuration

The required configuration can be broken down into 4 major pieces:

- A dummy interface for the provider-assigned IP;
- NAT (specifically, Source NAT);
- IPSec IKE and ESP Groups;
- IPSec VPN tunnels.

### Dummy interface

The dummy interface allows us to have an equivalent of the Cisco IOS Loopback interface - a router-internal interface we can use for IP addresses the router must know about, but which are not actually assigned to a real network.

We only need a single step for this interface:

```
set interfaces dummy dum0 address '172.29.41.89/32'
```

### NAT Configuration

```
set nat source rule 110 description 'Internal to ASP'
set nat source rule 110 destination address '172.27.1.0/24'
set nat source rule 110 source address '192.168.43.0/24'
set nat source rule 110 translation address '172.29.41.89'
set nat source rule 120 description 'Internal to ASP'
set nat source rule 120 destination address '10.125.0.0/16'
set nat source rule 120 source address '192.168.43.0/24'
set nat source rule 120 translation address '172.29.41.89'
```

## IPSec IKE and ESP

The ASP has documented their IPSec requirements:

- IKE Phase:
  - aes256 Encryption
  - sha256 Hashes
- ESP Phase:
  - aes256 Encryption
  - sha256 Hashes
  - DH Group 14

Additionally, we want to use VPNs only on our eth1 interface (the external interface in the image above)

```
set vpn ipsec ike-group my-ike key-exchange 'ikev1'
set vpn ipsec ike-group my-ike lifetime '7800'
set vpn ipsec ike-group my-ike proposal 1 dh-group '14'
set vpn ipsec ike-group my-ike proposal 1 encryption 'aes256'
set vpn ipsec ike-group my-ike proposal 1 hash 'sha256'

set vpn ipsec esp-group my-esp lifetime '3600'
set vpn ipsec esp-group my-esp mode 'tunnel'
set vpn ipsec esp-group my-esp pfs 'disable'
set vpn ipsec esp-group my-esp proposal 1 encryption 'aes256'
set vpn ipsec esp-group my-esp proposal 1 hash 'sha256'

set vpn ipsec interface 'eth1'
```

## IPSec VPN Tunnels

We'll use the IKE and ESP groups created above for this VPN. Because we need access to 2 different subnets on the far side, we will need two different tunnels. If you changed the names of the ESP group and IKE group in the previous step, make sure you use the correct names here too.

```
set vpn ipsec authentication psk vyos id '203.0.113.46'
set vpn ipsec authentication psk vyos id '198.51.100.243'
set vpn ipsec authentication psk vyos secret 'MYSECRETPASSWORD'
set vpn ipsec site-to-site peer branch authentication local-id '203.0.113.46'
set vpn ipsec site-to-site peer branch authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer branch authentication remote-id '198.51.100.243'
set vpn ipsec site-to-site peer branch connection-type 'initiate'
set vpn ipsec site-to-site peer branch default-esp-group 'my-esp'
set vpn ipsec site-to-site peer branch ike-group 'my-ike'
set vpn ipsec site-to-site peer branch ikev2-reauth 'inherit'
set vpn ipsec site-to-site peer branch local-address '203.0.113.46'
set vpn ipsec site-to-site peer branch remote-address '198.51.100.243'
set vpn ipsec site-to-site peer branch tunnel 0 local prefix '172.29.41.89/32'
set vpn ipsec site-to-site peer branch tunnel 0 remote prefix '172.27.1.0/24'
set vpn ipsec site-to-site peer branch tunnel 1 local prefix '172.29.41.89/32'
set vpn ipsec site-to-site peer branch tunnel 1 remote prefix '10.125.0.0/16'
```

## Testing and Validation

If you've completed all the above steps you no doubt want to see if it's all working.

Start by checking for IPsec SAs (Security Associations) with:

```
$ show vpn ipsec sa
```

Peer ID / IP			Local ID / IP						
-----			-----						
198.51.100.243			203.0.113.46						
Tunnel	State	Bytes Out/In	Encrypt	Hash	NAT-T	A-Time	L-Time	Proto	
-----	-----	-----	-----	-----	-----	-----	-----	-----	
0	up	0.0/0.0	aes256	sha256	no	1647	3600	all	
1	up	0.0/0.0	aes256	sha256	no	865	3600	all	

That looks good - we defined 2 tunnels and they're both up and running.

## 8.6.2 NAT64

NAT64 (IPv6-to-IPv4 Prefix Translation) is a critical component in modern networking, facilitating communication between IPv6 and IPv4 networks. This documentation outlines the setup, configuration, and usage of the NAT64 feature in your project. Whether you are transitioning to IPv6 or need to seamlessly connect IPv4 and IPv6 devices. NAT64 is a stateful translation mechanism that translates IPv6 addresses to IPv4 addresses and IPv4 addresses to IPv6 addresses. NAT64 is used to enable IPv6-only clients to contact IPv4 servers using unicast UDP, TCP, or ICMP.

### Overview

#### Different NAT Types

##### SNAT64

SNAT64 (IPv6-to-IPv4 Source Address Translation) is a stateful translation mechanism that translates IPv6 addresses to IPv4 addresses.

64:ff9b::/96 is the well-known prefix for IPv4-embedded IPv6 addresses. The prefix is used to represent IPv4 addresses in an IPv6 address format. The IPv4 address is encoded in the low-order 32 bits of the IPv6 address. The high-order 32 bits are set to the well-known prefix 64:ff9b::/96.

### Configuration Examples

The following examples show how to configure NAT64 on a VyOS router. The 192.0.2.10 address is used as the IPv4 address for the translation pool.

NAT64 server configuration:

```
set interfaces ethernet eth0 address '192.0.2.1/24'
set interfaces ethernet eth0 address '192.0.2.10/24'
set interfaces ethernet eth0 description 'WAN'
set interfaces ethernet eth1 address '2001:db8::1/64'
set interfaces ethernet eth1 description 'LAN'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set service dns forwarding allow-from '2001:db8::/64'
set service dns forwarding dns64-prefix '64:ff9b::/96'
set service dns forwarding listen-address '2001:db8::1'

set nat64 source rule 100 source prefix '64:ff9b::/96'
set nat64 source rule 100 translation pool 10 address '192.0.2.10'
set nat64 source rule 100 translation pool 10 port '1-65535'

```

NAT64 client configuration:

```

set interfaces ethernet eth1 address '2001:db8::2/64'
set protocols static route6 64:ff9b::/96 next-hop 2001:db8::1
set system name-server '2001:db8::1'

```

Test from the IPv6 only client:

```

vyos@r1:~$ ping 64:ff9b::192.0.2.1 count 2
PING 64:ff9b::192.0.2.1(64:ff9b::c000:201) 56 data bytes
64 bytes from 64:ff9b::c000:201: icmp_seq=1 ttl=63 time=0.351 ms
64 bytes from 64:ff9b::c000:201: icmp_seq=2 ttl=63 time=0.373 ms

--- 64:ff9b::192.0.2.1 ping statistics ---
2 packets transmitted, 2 received, 0% packet loss, time 1023ms
rtt min/avg/max/mdev = 0.351/0.362/0.373/0.011 ms

```

### 8.6.3 NAT66(NPTv6)

NPTv6 (IPv6-to-IPv6 Network Prefix Translation) is an address translation technology based on IPv6 networks, used to convert an IPv6 address prefix in an IPv6 message into another IPv6 address prefix. We call this address translation method NAT66. Devices that support the NAT66 function are called NAT66 devices, which can provide NAT66 source and destination address translation functions.

#### Overview

#### Different NAT Types

#### SNAT66

SNPTv6 (Source IPv6-to-IPv6 Network Prefix Translation) The conversion function is mainly used in the following scenarios:

- A single internal network and external network. Use the NAT66 device to connect a single internal network and public network, and the hosts in the internal network use IPv6 address prefixes that only support routing within the local range. When a host in the internal network accesses the external network, the source IPv6 address prefix in the message will be converted into a global unicast IPv6 address prefix by the NAT66 device.
- Redundancy and load sharing. There are multiple NAT66 devices at the edge of an IPv6 network to another IPv6 network. The path through the NAT66 device to another IPv6 network forms an equivalent route, and traffic can be load-shared on these NAT66 devices. In this case, you can configure the same source address translation rules on these NAT66 devices, so that any NAT66 device can handle IPv6 traffic between different sites.

- Multi-homed. In a multi-homed network environment, the NAT66 device connects to an internal network and simultaneously connects to different external networks. Address translation can be configured on each external network side interface of the NAT66 device to convert the same internal network address into different external network addresses, and realize the mapping of the same internal address to multiple external addresses.

## DNAT66

The DNPTv6 (Destination IPv6-to-IPv6 Network Prefix Translation) destination address translation function is used in scenarios where the server in the internal network provides services to the external network, such as providing Web services or FTP services to the external network. By configuring the mapping relationship between the internal server address and the external network address on the external network side interface of the NAT66 device, external network users can access the internal network server through the designated external network address.

### Prefix Conversion

#### Source Prefix

Every SNAT66 rule has a translation command defined. The prefix defined for the translation is the prefix used when the address information in a packet is replaced.

The *SNAT66* rule replaces the source address of the packet and calculates the converted address using the prefix specified in the rule.

Example:

- Convert the address prefix of a single *fc01::/64* network to *fc00::/64*
- Output from *eth0* network interface

```
set nat66 source rule 1 outbound-interface name 'eth0'
set nat66 source rule 1 source prefix 'fc01::/64'
set nat66 source rule 1 translation address 'fc00::/64'
```

#### Destination Prefix

For the *DNAT66* rule, the destination address of the packet is replaced by the address calculated from the specified address or prefix in the *translation address* command

Example:

- Convert the address prefix of a single *fc00::/64* network to *fc01::/64*
- Input from *eth0* network interface

```
set nat66 destination rule 1 inbound-interface name 'eth0'
set nat66 destination rule 1 destination address 'fc00::/64'
set nat66 destination rule 1 translation address 'fc01::/64'
```

## Configuration Examples

Use the following topology to build a nat66 based isolated network between internal and external networks (dynamic prefix is not supported):

R1:

```

set interfaces ethernet eth0 ipv6 address autoconf
set interfaces ethernet eth1 address 'fc01::1/64'
set nat66 destination rule 1 destination address 'fc00:470:f1cd:101::/64'
set nat66 destination rule 1 inbound-interface name 'eth0'
set nat66 destination rule 1 translation address 'fc01::/64'
set nat66 source rule 1 outbound-interface name 'eth0'
set nat66 source rule 1 source prefix 'fc01::/64'
set nat66 source rule 1 translation address 'fc00:470:f1cd:101::/64'

```

R2:

```

set interfaces bridge br1 address 'fc01::2/64'
set interfaces bridge br1 member interface eth0
set interfaces bridge br1 member interface eth1
set protocols static route6 ::/0 next-hop fc01::1
set service router-advert interface br1 prefix ::/0

```

Use the following topology to translate internal user local addresses (fc::/7) to DHCPv6-PD provided prefixes from an ISP connected to a VyOS HA pair.

Configure both routers (a and b) for DHCPv6-PD via dummy interface:

```

set interfaces dummy dum1 description 'DHCPv6-PD NPT dummy'
set interfaces bonding bond0 vif 20 dhcpv6-options pd 0 interface dum1 address '0'
set interfaces bonding bond0 vif 20 dhcpv6-options pd 1 interface dum1 address '0'

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set interfaces bonding bond0 vif 20 dhcpv6-options pd 2 interface dum1 address '0'
set interfaces bonding bond0 vif 20 dhcpv6-options pd 3 interface dum1 address '0'
set interfaces bonding bond0 vif 20 dhcpv6-options rapid-commit
commit

```

Get the DHCPv6-PD prefixes from both routers:

```

trae@cr01a-vyos# run show interfaces dummy dum1 br
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
dum1           2001:db8:123:b008::/64    u/u  DHCPv6-PD NPT dummy
              2001:db8:123:b00a::/64
              2001:db8:123:b00b::/64
              2001:db8:123:b009::/64

trae@cr01b-vyos# run show int dummy dum1 brief
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
dum1           2001:db8:123:b00d::/64    u/u  DHCPv6-PD NPT dummy
              2001:db8:123:b00c::/64
              2001:db8:123:b00e::/64
              2001:db8:123:b00f::/64

```

Configure the A-side router for NPTv6 using the prefixes above:

```

set nat66 source rule 10 description 'NPT to VLAN 10'
set nat66 source rule 10 outbound-interface name 'bond0.20'
set nat66 source rule 10 source prefix 'fd52:d62e:8011:a::/64'
set nat66 source rule 10 translation address '2001:db8:123:b008::/64'
set nat66 source rule 20 description 'NPT to VLAN 70'
set nat66 source rule 20 outbound-interface name 'bond0.20'
set nat66 source rule 20 source prefix 'fd52:d62e:8011:46::/64'
set nat66 source rule 20 translation address '2001:db8:123:b009::/64'
set nat66 source rule 30 description 'NPT to VLAN 200'
set nat66 source rule 30 outbound-interface name 'bond0.20'
set nat66 source rule 30 source prefix 'fd52:d62e:8011:c8::/64'
set nat66 source rule 30 translation address '2001:db8:123:b00a::/64'
set nat66 source rule 40 description 'NPT to VLAN 240'
set nat66 source rule 40 outbound-interface name 'bond0.20'
set nat66 source rule 40 source prefix 'fd52:d62e:8011:f0::/64'
set nat66 source rule 40 translation address '2001:db8:123:b00b::/64'
commit

```

Configure the B-side router for NPTv6 using the prefixes above:

```

set nat66 source rule 10 description 'NPT to VLAN 10'
set nat66 source rule 10 outbound-interface name 'bond0.20'
set nat66 source rule 10 source prefix 'fd52:d62e:8011:a::/64'
set nat66 source rule 10 translation address '2001:db8:123:b00c::/64'
set nat66 source rule 20 description 'NPT to VLAN 70'
set nat66 source rule 20 outbound-interface name 'bond0.20'

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set nat66 source rule 20 source prefix 'fd52:d62e:8011:46::/64'
set nat66 source rule 20 translation address '2001:db8:123:b00d::/64'
set nat66 source rule 30 description 'NPT to VLAN 200'
set nat66 source rule 30 outbound-interface name 'bond0.20'
set nat66 source rule 30 source prefix 'fd52:d62e:8011:c8::/64'
set nat66 source rule 30 translation address '2001:db8:123:b00e::/64'
set nat66 source rule 40 description 'NPT to VLAN 240'
set nat66 source rule 40 outbound-interface name 'bond0.20'
set nat66 source rule 40 source prefix 'fd52:d62e:8011:f0::/64'
set nat66 source rule 40 translation address '2001:db8:123:b00f::/64'
commit

```

Verify that connections are hitting the rule on both sides:

```

trae@cr01a-vyos# run show nat66 source statistics
Rule      Packets      Bytes      Interface
-----
10         1           104      bond0.20
20         1           104      bond0.20
30        8093       669445    bond0.20
40        2446       216912    bond0.20

```

## 8.6.4 CGNAT

CGNAT (Carrier-Grade Network Address Translation), also known as Large-Scale NAT (LSN), is a type of network address translation used by Internet Service Providers (ISPs) to enable multiple private IP addresses to share a single public IP address. This technique helps to conserve the limited IPv4 address space. The 100.64.0.0/10 address block is reserved for use in carrier-grade NAT.

### Overview

CGNAT works by placing a NAT device within the ISP's network. This device translates private IP addresses from customer networks to a limited pool of public IP addresses assigned to the ISP. This allows many customers to share a smaller number of public IP addresses.

Not all [RFC 6888](#) requirements are implemented in CGNAT.

Implemented the following [RFC 6888](#) requirements:

- REQ 2: A CGN must have a default „IP address pooling“ behavior of „Paired“. CGN must use the same external IP address mapping for all sessions associated with the same internal IP address, be they TCP, UDP, ICMP, something else, or a mix of different protocols.
- REQ 3: The CGN function should not have any limitations on the size or the contiguity of the external address pool.
- REQ 4: A CGN must support limiting the number of external ports (or, equivalently, „identifiers“ for ICMP) that are assigned per subscriber

## Advantages of CGNAT

- **IPv4 Address Conservation:** CGNAT helps mitigate the exhaustion of IPv4 addresses by allowing multiple customers to share a single public IP address.
- **Scalability:** ISPs can support more customers without needing a proportional increase in public IP addresses.
- **Cost-Effective:** Reduces the cost associated with acquiring additional public IPv4 addresses.

## Considerations

- **Traceability Issues:** Since multiple users share the same public IP address, tracking individual users for security and legal purposes can be challenging.
- **Performance Overheads:** The translation process can introduce latency and potential performance bottlenecks, especially under high load.
- **Application Compatibility:** Some applications and protocols may not work well with CGNAT due to their reliance on unique public IP addresses.
- **Port Allocation Limits:** Each public IP address has a limited number of ports, which can be exhausted, affecting the ability to establish new connections.
- **Port Control Protocol:** PCP is not implemented.

## Port calculation

When implementing CGNAT, ensuring that there are enough ports allocated per subscriber is critical. Below is a summary based on RFC 6888.

### 1. Total Ports Available:

- Total Ports: 65536 (0 to 65535)
- Reserved Ports: Assume 1024 ports are reserved for well-known services and administrative purposes.
- Usable Ports:  $65536 - 1024 = 64512$

### 2. Estimate Ports Needed per Subscriber:

- Example: A household might need 1000 ports to ensure smooth operation for multiple devices and applications.

### 3. Calculate the Number of Subscribers per Public IP:

- Usable Ports / Ports per Subscriber
- $64512 / 1000 = 64$  subscribers per public IP

## Configuration

**set nat cgnat pool external <pool-name> external-port-range <port-range>**

Set an external port-range for the external pool, the default range is 1024-65535. Multiple entries can be added to the same pool.

**set nat cgnat pool external <pool-name> external-port-range per-user-limit port <num>**

Set external source port limits that will be allocated to each subscriber individually. The default value is 2000.

**set nat cgnat pool external <pool-name> range [address | address range | network]**

Set the range of external IP addresses for the CGNAT pool.

**set nat cgnat pool internal <pool-name> range [address range | network]**

Set the range of internal IP addresses for the CGNAT pool.

**set nat cgnat pool rule <num> source pool <internal-pool-name>**

Set the rule for the source pool.

**set nat cgnat pool rule <num> translation pool <external-pool-name>**

Set the rule for the translation pool.

## Configuration Examples

### Single external address

Example of setting up a basic CGNAT configuration: In the following example, we define an external pool named *ext-1* with one external IP address

Each subscriber will be allocated a maximum of 2000 ports from the external pool.

```
set nat cgnat pool external ext1 external-port-range '1024-65535'
set nat cgnat pool external ext1 per-user-limit port '2000'
set nat cgnat pool external ext1 range '192.0.2.222/32'
set nat cgnat pool internal int1 range '100.64.0.0/28'
set nat cgnat rule 10 source pool 'int1'
set nat cgnat rule 10 translation pool 'ext1'
```

### Multiple external addresses

```
set nat cgnat pool external ext1 external-port-range '1024-65535'
set nat cgnat pool external ext1 per-user-limit port '8000'
set nat cgnat pool external ext1 range '192.0.2.1-192.0.2.2'
set nat cgnat pool external ext1 range '203.0.113.253-203.0.113.254'
set nat cgnat pool internal int1 range '100.64.0.1-100.64.0.32'
set nat cgnat rule 10 source pool 'int1'
set nat cgnat rule 10 translation pool 'ext1'
```

## 8.7 Policy

Policies are used for filtering and traffic management. With policies, network administrators could filter and treat traffic according to their needs.

There could be a wide range of routing policies. Some examples are listed below:

- Filter traffic based on source/destination address.
- Set some metric to routes learned from a particular neighbor.
- Set some attributes (like AS PATH or Community value) to advertised routes to neighbors.
- Prefer a specific routing protocol routes over another routing protocol running on the same router.

Policies, in VyOS, are implemented using FRR filtering and route maps. Detailed information of FRR could be found in <http://docs.frrouting.org/>

### 8.7.1 Policy Sections

#### Access List Policy

Filtering is used for both input and output of the routing information. Once filtering is defined, it can be applied in any direction. VyOS makes filtering possible using acls and prefix lists.

Basic filtering can be done using access-list and access-list6.

## Configuration

### Access Lists

```
set policy access-list <acl_number>
```

This command creates the new access list policy, where <acl\_number> must be a number from 1 to 2699.

```
set policy access-list <acl_number> description <text>
```

Set description for the access list.

```
set policy access-list <acl_number> rule <1-65535> action <permit|deny>
```

This command creates a new rule in the access list and defines an action.

```
set policy access-list <acl_number> rule <1-65535> <destination|source>  
<any|host|inverse-mask|network>
```

This command defines matching parameters for access list rule. Matching criteria could be applied to destination or source parameters:

- any: any IP address to match.

- host: single host IP address to match.
- inverse-match: network/netmask to match (requires network be defined).
- network: network/netmask to match (requires inverse-match be defined).

## IPv6 Access List

Basic filtering could also be applied to IPv6 traffic.

**set policy access-list6 <text>**

This command creates the new IPv6 access list, identified by <text>

**set policy access-list6 <text> description <text>**

Set description for the IPv6 access list.

**set policy access-list6 <text> rule <1-65535> action <permit|deny>**

This command creates a new rule in the IPv6 access list and defines an action.

**set policy access-list6 <text> rule <1-65535> source <any|exact-match|network>**

This command defines matching parameters for IPv6 access list rule. Matching criteria could be applied to source parameters:

- any: any IPv6 address to match.
- exact-match: exact match of the network prefixes.
- network: network/netmask to match (requires inverse-match be defined) BUG, NO invert-match option in access-list6

## Prefix List Policy

Prefix lists provides the most powerful prefix based filtering mechanism. In addition to access-list functionality, ip prefix-list has prefix length range specification.

If no ip prefix list is specified, it acts as permit. If ip prefix list is defined, and no match is found, default deny is applied.

Prefix filtering can be done using prefix-list and prefix-list6.

## Configuration

### Prefix Lists

**set policy prefix-list <text>**

This command creates the new prefix-list policy, identified by <text>.

**set policy prefix-list <text> description <text>**

Set description for the prefix-list policy.

**set policy prefix-list <text> rule <1-65535> action <permit|deny>**

This command creates a new rule in the prefix-list and defines an action.

**set policy prefix-list <text> rule <1-65535> description <text>**

Set description for rule in the prefix-list.

```
set policy prefix-list <text> rule <1-65535> prefix <x.x.x.x/x>
```

Prefix to match against.

```
set policy prefix-list <text> rule <1-65535> ge <0-32>
```

Netmask greater than length.

```
set policy prefix-list <text> rule <1-65535> le <0-32>
```

Netmask less than length

## IPv6 Prefix Lists

```
set policy prefix-list6 <text>
```

This command creates the new IPv6 prefix-list policy, identified by <text>.

```
set policy prefix-list6 <text> description <text>
```

Set description for the IPv6 prefix-list policy.

```
set policy prefix-list6 <text> rule <1-65535> action <permit|deny>
```

This command creates a new rule in the IPv6 prefix-list and defines an action.

```
set policy prefix-list6 <text> rule <1-65535> description <text>
```

Set description for rule in IPv6 prefix-list.

```
set policy prefix-list6 <text> rule <1-65535> prefix <h:h:h:h:h:h:h/x>
```

IPv6 prefix.

```
set policy prefix-list6 <text> rule <1-65535> ge <0-128>
```

Netmask greater than length.

```
set policy prefix-list6 <text> rule <1-65535> le <0-128>
```

Netmask less than length

## Route and Route6 Policy

IPv4 route and IPv6 route policies are defined in this section. These route policies can then be associated to interfaces.

### Rule-Sets

A rule-set is a named collection of rules that can be applied to an interface. Each rule is numbered, has an action to apply if the rule is matched, and the ability to specify the criteria to match. Data packets go through the rules from 1 - 999999, at the first match the action of the rule will be executed.

```
set policy route <name> description <text>
```

```
set policy route6 <name> description <text>
```

Provide a rule-set description.

```
set policy route <name> default-log
```

```
set policy route6 <name> default-log
```

Option to log packets hitting default-action.

```
set policy route <name> rule <n> description <text>
set policy route6 <name> rule <n> description <text>
```

Provide a description for each rule.

```
set policy route <name> rule <n> log <enable|disable>
set policy route6 <name> rule <n> log <enable|disable>
```

Option to enable or disable log matching rule.

## Matching criteria

There are a lot of matching criteria options available, both for `policy route` and `policy route6`. These options are listed in this section.

```
set policy route <name> rule <n> connection-mark <1-2147483647>
set policy route6 <name> rule <n> connection-mark <1-2147483647>
```

Set match criteria based on connection mark.

```
set policy route <name> rule <n> source address <match_criteria>
set policy route <name> rule <n> destination address <match_criteria>
set policy route6 <name> rule <n> source address <match_criteria>
set policy route6 <name> rule <n> destination address <match_criteria>
```

Set match criteria based on source or destination ipv4|ipv6 address, where `<match_criteria>` could be:

### For ipv4:

- `<x.x.x.x>`: IP address to match.
- `<x.x.x.x/x>`: Subnet to match.
- `<x.x.x.x>-<x.x.x.x>`: IP range to match.
- `!<x.x.x.x>`: Match everything except the specified address.
- `!<x.x.x.x/x>`: Match everything except the specified subnet.
- `!<x.x.x.x>-<x.x.x.x>`: Match everything except the specified range.

### And for ipv6:

- `<h:h:h:h:h:h:h>`: IPv6 address to match.
- `<h:h:h:h:h:h:h/x>`: IPv6 prefix to match.
- `<h:h:h:h:h:h:h>-<h:h:h:h:h:h:h>`: IPv6 range to match.
- `!<h:h:h:h:h:h:h>`: Match everything except the specified address.
- `!<h:h:h:h:h:h:h/x>`: Match everything except the specified prefix.
- `!<h:h:h:h:h:h:h>-<h:h:h:h:h:h:h>`: Match everything except the specified range.

```
set policy route <name> rule <n> source group <address-group|domain-group|mac-group|network-group|port-group> <text>
set policy route <name> rule <n> destination group <address-group|domain-group|mac-group|network-group|port-group> <text>
```

```
set policy route6 <name> rule <n> source group <address-group|domain-group|mac-group|network-group|port-
<text>
```

```
set policy route6 <name> rule <n> destination group <address-group|domain-group|mac-group|network-group
<text>
```

Set match criteria based on source or destination groups, where <text> would be the group name/identifier.

Prepend character ,i for inverted matching criteria.

```
set policy route <name> rule <n> destination port <match_criteria>
```

```
set policy route6 <name> rule <n> destination port <match_criteria>
```

Set match criteria based on destination port, where <match\_criteria> could be:

- <port name>: Named port (any name in /etc/services, e.g., http).
- <1-65535>: Numbered port.
- <start>-<end>: Numbered port range (e.g., 1001-1005).

Multiple destination ports can be specified as a comma-separated list. The whole list can also be „negated“ using ,i. For example: ,!22,telnet,http,123,1001-1005‘

```
set policy route <name> rule <n> disable
```

```
set policy route6 <name> rule <n> disable
```

Option to disable rule.

```
set policy route <name> rule <n> dscp <text>
```

```
set policy route6 <name> rule <n> dscp <text>
```

```
set policy route <name> rule <n> dscp-exclude <text>
```

```
set policy route6 <name> rule <n> dscp-exclude <text>
```

Match based on dscp value criteria. Multiple values from 0 to 63 and ranges are supported.

```
set policy route <name> rule <n> fragment <match-grag|match-non-frag>
```

```
set policy route6 <name> rule <n> fragment <match-grag|match-non-frag>
```

Set IP fragment match, where:

- match-frag: Second and further fragments of fragmented packets.
- match-non-frag: Head fragments or unfragmented packets.

```
set policy route <name> rule <n> icmp <code | type>
```

```
set policy route6 <name> rule <n> icmpv6 <code | type>
```

Match based on icmp|icmpv6 code and type.

```
set policy route <name> rule <n> icmp type-name <text>
```

```
set policy route6 <name> rule <n> icmpv6 type-name <text>
```

Match based on icmp|icmpv6 type-name criteria. Use tab for information about what type-name criteria are supported.

```
set policy route <name> rule <n> ipsec <match-ipsec|match-none>
```

```
set policy route6 <name> rule <n> ipsec <match-ipsec|match-none>
```

Set IPSec inbound match criterias, where:

- match-ipsec: match inbound IPsec packets.

- match-none: match inbound non-IPsec packets.

```
set policy route <name> rule <n> limit burst <0-4294967295>
```

```
set policy route6 <name> rule <n> limit burst <0-4294967295>
```

Set maximum number of packets to allow in excess of rate.

```
set policy route <name> rule <n> limit rate <text>
```

```
set policy route6 <name> rule <n> limit rate <text>
```

Set maximum average matching rate. Format for rate: integer/time\_unit, where time\_unit could be any one of second, minute, hour or day. For example 1/second implies rule to be matched at an average of once per second.

```
set policy route <name> rule <n> protocol <text | 0-255 | tcp_udp | all >
```

```
set policy route6 <name> rule <n> protocol <text | 0-255 | tcp_udp | all >
```

Match a protocol criteria. A protocol number or a name which is defined in: /etc/protocols. Special names are all for all protocols and tcp\_udp for tcp and udp based packets. The ! negates the selected protocol.

```
set policy route <name> rule <n> packet-length <text>
```

```
set policy route6 <name> rule <n> packet-length <text>
```

```
set policy route <name> rule <n> packet-length-exclude <text>
```

```
set policy route6 <name> rule <n> packet-length-exclude <text>
```

Match based on packet length criteria. Multiple values from 1 to 65535 and ranges are supported.

```
set policy route <name> rule <n> packet-type [broadcast | host | multicast | other]
```

```
set policy route6 <name> rule <n> packet-type [broadcast | host | multicast | other]
```

Match based on packet type criteria.

```
set policy route <name> rule <n> recent count <1-255>
```

```
set policy route6 <name> rule <n> recent count <1-255>
```

```
set policy route <name> rule <n> recent time <1-4294967295>
```

```
set policy route6 <name> rule <n> recent time <1-4294967295>
```

Set parameters for matching recently seen sources. This match could be used by setting count (source address seen more than <1-255> times) and/or time (source address seen in the last <0-4294967295> seconds).

```
set policy route <name> rule <n> state <established | invalid | new | related>
```

```
set policy route6 <name> rule <n> state <established | invalid | new | related>
```

Set match criteria based on session state.

```
set policy route <name> rule <n> tcp flags <text>
```

```
set policy route6 <name> rule <n> tcp flags <text>
```

Set match criteria based on tcp flags. Allowed values for TCP flags: SYN ACK FIN RST URG PSH ALL. When specifying more than one flag, flags should be comma-separated. For example : value of ,SYN,!ACK,!FIN,!RST' will only match packets with the SYN flag set, and the ACK, FIN and RST flags unset.

```
set policy route <name> rule <n> time monthdays <text>
```

```
set policy route6 <name> rule <n> time monthdays <text>
```

```
set policy route <name> rule <n> time startdate <text>
```

```
set policy route6 <name> rule <n> time startdate <text>
```

```

set policy route <name> rule <n> time starttime <text>
set policy route6 <name> rule <n> time starttime <text>
set policy route <name> rule <n> time stopdate <text>
set policy route6 <name> rule <n> time stopdate <text>
set policy route <name> rule <n> time stoptime <text>
set policy route6 <name> rule <n> time stoptime <text>
set policy route <name> rule <n> time weekdays <text>
set policy route6 <name> rule <n> time weekdays <text>
set policy route <name> rule <n> time utc
set policy route6 <name> rule <n> time utc

```

Time to match the defined rule.

```
set policy route rule <n> ttl <eq | gt | lt> <0-255>
```

Match time to live parameter, where ,eq' stands for ,equal'; ,gt' stands for ,greater than', and ,lt' stands for ,less than'.

```
set policy route6 rule <n> hop-limit <eq | gt | lt> <0-255>
```

Match hop-limit parameter, where ,eq' stands for ,equal'; ,gt' stands for ,greater than', and ,lt' stands for ,less than'.

## Actions

When matching all patterns defined in a rule, then different actions can be made. This includes dropping the packet, modifying certain data, or setting a different routing table.

```

set policy route <name> rule <n> action drop
set policy route6 <name> rule <n> action drop

```

Set rule action to drop.

```

set policy route <name> rule <n> set connection-mark <1-2147483647>
set policy route6 <name> rule <n> set connection-mark <1-2147483647>

```

Set a specific connection mark.

```

set policy route <name> rule <n> set dscp <0-63>
set policy route6 <name> rule <n> set dscp <0-63>

```

Set packet modifications: Packet Differentiated Services Codepoint (DSCP)

```

set policy route <name> rule <n> set mark <1-2147483647>
set policy route6 <name> rule <n> set mark <1-2147483647>

```

Set a specific packet mark.

```

set policy route <name> rule <n> set table <main | 1-200>
set policy route6 <name> rule <n> set table <main | 1-200>

```

Set the routing table to forward packet with.

```
set policy route <name> rule <n> set tcp-mss <500-1460>
```

```
set policy route6 <name> rule <n> set tcp-mss <500-1460>
```

Set packet modifications: Explicitly set TCP Maximum segment size value.

## Route Map Policy

Route map is a powerfull command, that gives network administrators a very useful and flexible tool for traffic manipulation.

## Configuration

### Route Map

```
set policy route-map <text>
```

This command creates a new route-map policy, identified by <text>.

```
set policy route-map <text> description <text>
```

Set description for the route-map policy.

```
set policy route-map <text> rule <1-65535> action <permit|deny>
```

Set action for the route-map policy.

```
set policy route-map <text> rule <1-65535> call <text>
```

Call another route-map policy on match.

```
set policy route-map <text> rule <1-65535> continue <1-65535>
```

Jump to a different rule in this route-map on a match.

```
set policy route-map <text> rule <1-65535> description <text>
```

Set description for the rule in the route-map policy.

```
set policy route-map <text> rule <1-65535> match as-path <text>
```

BGP as-path list to match.

```
set policy route-map <text> rule <1-65535> match community community-list <text>
```

BGP community-list to match.

```
set policy route-map <text> rule <1-65535> match community exact-match
```

Set BGP community-list to exactly match.

```
set policy route-map <text> rule <1-65535> match extcommunity <text>
```

BGP extended community to match.

```
set policy route-map <text> rule <1-65535> match interface <text>
```

First hop interface of a route to match.

```
set policy route-map <text> rule <1-65535> match ip address access-list <1-2699>
```

IP address of route to match, based on access-list.

```
set policy route-map <text> rule <1-65535> match ip address prefix-list <text>
```

IP address of route to match, based on prefix-list.

**set policy route-map <text> rule <1-65535> match ip address prefix-len <0-32>**

IP address of route to match, based on specified prefix-length. Note that this can be used for kernel routes only. Do not apply to the routes of dynamic routing protocols (e.g. BGP, RIP, OSPF), as this can lead to unexpected results..

**set policy route-map <text> rule <1-65535> match ip nexthop access-list <1-2699>**

IP next-hop of route to match, based on access-list.

**set policy route-map <text> rule <1-65535> match ip nexthop address <x.x.x.x>**

IP next-hop of route to match, based on ip address.

**set policy route-map <text> rule <1-65535> match ip nexthop prefix-len <0-32>**

IP next-hop of route to match, based on prefix length.

**set policy route-map <text> rule <1-65535> match ip nexthop prefix-list <text>**

IP next-hop of route to match, based on prefix-list.

**set policy route-map <text> rule <1-65535> match ip nexthop type <blackhole>**

IP next-hop of route to match, based on type.

**set policy route-map <text> rule <1-65535> match ip route-source access-list <1-2699>**

IP route source of route to match, based on access-list.

**set policy route-map <text> rule <1-65535> match ip route-source prefix-list <text>**

IP route source of route to match, based on prefix-list.

**set policy route-map <text> rule <1-65535> match ipv6 address access-list <text>**

IPv6 address of route to match, based on IPv6 access-list.

**set policy route-map <text> rule <1-65535> match ipv6 address prefix-list <text>**

IPv6 address of route to match, based on IPv6 prefix-list.

**set policy route-map <text> rule <1-65535> match ipv6 address prefix-len <0-128>**

IPv6 address of route to match, based on specified prefix-length. Note that this can be used for kernel routes only. Do not apply to the routes of dynamic routing protocols (e.g. BGP, RIP, OSPF), as this can lead to unexpected results..

**set policy route-map <text> rule <1-65535> match ipv6 nexthop <h:h:h:h:h:h:h>**

Nexthop IPv6 address to match.

**set policy route-map <text> rule <1-65535> match large-community large-community-list <text>**

Match BGP large communities.

**set policy route-map <text> rule <1-65535> match local-preference <0-4294967295>**

Match local preference.

**set policy route-map <text> rule <1-65535> match metric <1-65535>**

Match route metric.

**set policy route-map <text> rule <1-65535> match origin <egp|igp|incomplete>**

Boarder Gateway Protocol (BGP) origin code to match.

**set policy route-map <text> rule <1-65535> match peer <x.x.x.x>**

Peer IP address to match.

```
set policy route-map <text> rule <1-65535> match protocol <protocol>
```

Source protocol to match.

- **babel** - Babel routing protocol (Babel)
- **bgp** - Border Gateway Protocol (BGP)
- **connected** - Connected routes (directly attached subnet or host)
- **isis** - Intermediate System to Intermediate System (IS-IS)
- **kernel** - Kernel routes
- **ospf** - Open Shortest Path First (OSPFv2)
- **ospfv3** - Open Shortest Path First (IPv6) (OSPFv3)
- **rip** - Routing Information Protocol (RIP)
- **ripng** - Routing Information Protocol next-generation (IPv6) (RIPng)
- **static** - Statically configured routes
- **table** - Non-main Kernel Routing Table
- **vnc** - Virtual Network Control (VNC)

```
set policy route-map <text> rule <1-65535> match rpki <invalid|notfound|valid>
```

Match RPKI validation result.

```
set policy route-map <text> rule <1-65535> match tag <1-65535>
```

Route tag to match.

```
set policy route-map <text> rule <1-65535> on-match goto <1-65535>
```

Exit policy on match: go to rule <1-65535>

```
set policy route-map <text> rule <1-65535> on-match next
```

Exit policy on match: go to next sequence number.

```
set policy route-map <text> rule <1-65535> set aggregator <as|ip> <1-4294967295|x.x.x.x>
```

BGP aggregator attribute: AS number or IP address of an aggregation.

```
set policy route-map <text> rule <1-65535> set as-path exclude <1-4294967295 | all>
```

Drop AS-NUMBER from the BGP AS path.

If all is specified, remove all AS numbers from the AS\_PATH of the BGP path's NLRI.

```
set policy route-map <text> rule <1-65535> set as-path prepend <1-4294967295>
```

Prepend the given string of AS numbers to the AS\_PATH of the BGP path's NLRI.

```
set policy route-map <text> rule <1-65535> set as-path prepend-last-as <n>
```

Prepend the existing last AS number (the leftmost ASN) to the AS\_PATH.

```
set policy route-map <text> rule <1-65535> set atomic-aggregate
```

BGP atomic aggregate attribute.

```
set policy route-map <text> rule <1-65535> set community <add|replace> <community>
```

Add or replace BGP community attribute in format <0-65535:0-65535> or from well-known community list

```
set policy route-map <text> rule <1-65535> set community none
```

Delete all BGP communities

```
set policy route-map <text> rule <1-65535> set community delete <text>
```

Delete BGP communities matching the community-list.

```
set policy route-map <text> rule <1-65535> set large-community <add|replace>  
<GA:LDP1:LDP2>
```

Add or replace BGP large-community attribute in format <0-4294967295:0-4294967295:0-4294967295>

```
set policy route-map <text> rule <1-65535> set large-community none
```

Delete all BGP large-communities

```
set policy route-map <text> rule <1-65535> set large-community delete <text>
```

Delete BGP communities matching the large-community-list.

```
set policy route-map <text> rule <1-65535> set extcommunity bandwidth  
<1-25600|cumulative|num-multipaths>
```

Set extcommunity bandwidth

```
set policy route-map <text> rule <1-65535> set extcommunity bandwidth-non-transitive
```

The link bandwidth extended community is encoded as non-transitive

```
set policy route-map <text> rule <1-65535> set extcommunity rt <text>
```

Set route target value in format <0-65535:0-4294967295> or <IP:0-65535>.

```
set policy route-map <text> rule <1-65535> set extcommunity soo <text>
```

Set site of origin value in format <0-65535:0-4294967295> or <IP:0-65535>.

```
set policy route-map <text> rule <1-65535> set extcommunity none
```

Clear all BGP extcommunities.

```
set policy route-map <text> rule <1-65535> set distance <0-255>
```

Locally significant administrative distance.

```
set policy route-map <text> rule <1-65535> set ip-next-hop <x.x.x.x>
```

Nexthop IP address.

```
set policy route-map <text> rule <1-65535> set ip-next-hop unchanged
```

Set the next-hop as unchanged. Pass through the route-map without changing its value

```
set policy route-map <text> rule <1-65535> set ip-next-hop peer-address
```

Set the BGP nexthop address to the address of the peer. For an incoming route-map this means the ip address of our peer is used. For an outgoing route-map this means the ip address of our self is used to establish the peering with our neighbor.

```
set policy route-map <text> rule <1-65535> set ipv6-next-hop <global|local>  
<h:h:h:h:h:h:h>
```

Nexthop IPv6 address.

```
set policy route-map <text> rule <1-65535> set ipv6-next-hop peer-address
```

Set the BGP nexthop address to the address of the peer. For an incoming route-map this means the ip address of our peer is used. For an outgoing route-map this means the ip address of our self is used to establish the peering with our neighbor.

```
set policy route-map <text> rule <1-65535> set ipv6-next-hop prefer-global
```

For Incoming and Import Route-maps if we receive a v6 global and v6 LL address for the route, then prefer to use the global address as the nexthop.

```
set policy route-map <text> rule <1-65535> set local-preference <0-4294967295>
```

Set BGP local preference attribute.

```
set policy route-map <text> rule <1-65535> set metric <+/-metric|0-4294967295|rtt|+rtt|-rtt>
```

Set the route metric. When used with BGP, set the BGP attribute MED to a specific value. Use +/- to add or subtract the specified value to/from the existing/MED. Use rtt to set the MED to the round trip time or +rtt/-rtt to add/subtract the round trip time to/from the MED.

```
set policy route-map <text> rule <1-65535> set metric-type <type-1|type-2>
```

Set OSPF external metric-type.

```
set policy route-map <text> rule <1-65535> set origin <igp|egp|incomplete>
```

Set BGP origin code.

```
set policy route-map <text> rule <1-65535> set originator-id <x.x.x.x>
```

Set BGP originator ID attribute.

```
set policy route-map <text> rule <1-65535> set src <x.x.x.x|h:h:h:h:h:h:h:h>
```

Set source IP/IPv6 address for route.

```
set policy route-map <text> rule <1-65535> set table <1-200>
```

Set prefixes to table.

```
set policy route-map <text> rule <1-65535> set tag <1-65535>
```

Set tag value for routing protocol.

```
set policy route-map <text> rule <1-65535> set weight <0-4294967295>
```

Set BGP weight attribute

## List of well-known communities

- local-as - Well-known communities value NO\_EXPORT\_SUBCONFED 0xFFFFFFFF03
- no-advertise - Well-known communities value NO\_ADVERTISE 0xFFFFFFFF02
- no-export - Well-known communities value NO\_EXPORT 0xFFFFFFFF01
- internet - Well-known communities value 0
- graceful-shutdown - Well-known communities value GRACEFUL\_SHUTDOWN 0xFFFF0000
- accept-own - Well-known communities value ACCEPT\_OWN 0xFFFF0001
- route-filter-translated-v4 - Well-known communities value ROUTE\_FILTER\_TRANSLATED\_v4 0xFFFF0002
- route-filter-v4 - Well-known communities value ROUTE\_FILTER\_v4 0xFFFF0003

- `route-filter-translated-v6` - Well-known communities value `ROUTE_FILTER_TRANSLATED_v6 0xFFFF0004`
- `route-filter-v6` - Well-known communities value `ROUTE_FILTER_v6 0xFFFF0005`
- `llgr-stale` - Well-known communities value `LLGR_STALE 0xFFFF0006`
- `no-llgr` - Well-known communities value `NO_LLGR 0xFFFF0007`
- `accept-own-nexthop` - Well-known communities value `accept-own-nexthop 0xFFFF0008`
- `blackhole` - Well-known communities value `BLACKHOLE 0xFFFF029A`
- `no-peer` - Well-known communities value `NOPEER 0xFFFFFFFF04`

## Local Route Policy

Policies for local traffic are defined in this section.

## Configuration

### Local Route IPv4

```
set policy local-route rule <1-32765> set table <1-200|main>
```

Set routing table to forward packet to.

```
set policy local-route rule <1-32765> source <x.x.x.x|x.x.x.x/x>
```

Set source address or prefix to match.

```
set policy local-route rule <1-32765> destination <x.x.x.x|x.x.x.x/x>
```

Set destination address or prefix to match.

```
set policy local-route rule <1-32765> inbound-interface <interface>
```

Set inbound interface to match.

### Local Route IPv6

```
set policy local-route6 rule <1-32765> set table <1-200|main>
```

Set routing table to forward packet to.

```
set policy local-route6 rule <1-32765> source <h:h:h:h:h:h:h | h:h:h:h:h:h:h/x>
```

Set source address or prefix to match.

```
set policy local-route6 rule <1-32765> destination <h:h:h:h:h:h:h:h | h:h:h:h:h:h:h:h/x>
```

Set destination address or prefix to match.

```
set policy local-route6 rule <1-32765> inbound-interface <interface>
```

Set inbound interface to match.

## BGP - AS Path Policy

VyOS provides policies commands exclusively for BGP traffic filtering and manipulation: **as-path-list** is one of them.

### Configuration

#### policy as-path-list

**set policy as-path-list <text>**

Create as-path-policy identified by name <text>.

**set policy as-path-list <text> description <text>**

Set description for as-path-list policy.

**set policy as-path-list <text> rule <1-65535> action <permit|deny>**

Set action to take on entries matching this rule.

**set policy as-path-list <text> rule <1-65535> description <text>**

Set description for rule.

**set policy as-path-list <text> rule <1-65535> regex <text>**

Regular expression to match against an AS path. For example „64501 64502“.

## BGP - Community List

VyOS provides policies commands exclusively for BGP traffic filtering and manipulation: **community-list** is one of them.

### Configuration

#### policy community-list

**set policy community-list <text>**

Creat community-list policy identified by name <text>.

**set policy community-list <text> description <text>**

Set description for community-list policy.

**set policy community-list <text> rule <1-65535> action <permit|deny>**

Set action to take on entries matching this rule.

**set policy community-list <text> rule <1-65535> description <text>**

Set description for rule.

**set policy community-list <text> rule <1-65535> regex <aa:nn|local-AS|no-advertise|no-export|internet|a**

Regular expression to match against a community-list.

## BGP - Extended Community List

VyOS provides policies commands exclusively for BGP traffic filtering and manipulation: **extcommunity-list** is one of them.

### Configuration

#### policy extcommunity-list

```
set policy extcommunity-list <text>
```

Create extcommunity-list policy identified by name <text>.

```
set policy extcommunity-list <text> description <text>
```

Set description for extcommunity-list policy.

```
set policy extcommunity-list <text> rule <1-65535> action <permit|deny>
```

Set action to take on entries matching this rule.

```
set policy extcommunity-list <text> rule <1-65535> description <text>
```

Set description for rule.

```
set policy extcommunity-list <text> rule <1-65535> regex <text>
```

Regular expression to match against an extended community list, where text could be:

- <aa:nn:nn>: Extended community list regular expression.
- <rt aa:nn:nn>: Route Target regular expression.
- <soo aa:nn:nn>: Site of Origin regular expression.

## BGP - Large Community List

VyOS provides policies commands exclusively for BGP traffic filtering and manipulation: **large-community-list** is one of them.

### Configuration

#### policy large-community-list

```
set policy large-community-list <text>
```

Create large-community-list policy identified by name <text>.

```
set policy large-community-list <text> description <text>
```

Set description for large-community-list policy.

```
set policy large-community-list <text> rule <1-65535> action <permit|deny>
```

Set action to take on entries matching this rule.

```
set policy large-community-list <text> rule <1-65535> description <text>
```

Set description for rule.

```
set policy large-community-list <text> rule <1-65535> regex <aa:nn:nn>
```

Regular expression to match against a large community list.

## 8.7.2 Examples

Examples of policies usage:

### BGP Example

**Policy definition:**

```
# Create policy
set policy route-map setmet rule 2 action 'permit'
set policy route-map setmet rule 2 set as-path prepend '2 2 2'

# Apply policy to BGP
set protocols bgp system-as 1
set protocols bgp neighbor 203.0.113.2 address-family ipv4-unicast route-map import
↪ 'setmet'
set protocols bgp neighbor 203.0.113.2 address-family ipv4-unicast soft-reconfiguration
↪ 'inbound'
```

Using ,soft-reconfiguration' we get the policy update without bouncing the neighbor.

**Routes learned before routing policy applied:**

```
vyos@vos1:~$ show ip bgp
BGP table version is 0, local router ID is 192.168.56.101
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               r RIB-failure, S Stale, R Removed
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop          Metric LocPrf Weight Path
*> 198.51.100.3/32   203.0.113.2          1             0 2 i < Path

Total number of prefixes 1
```

**Routes learned after routing policy applied:**

```
vyos@vos1:~$ show ip bgp
BGP table version is 0, local router ID is 192.168.56.101
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               r RIB-failure, S Stale, R Removed
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop          Metric LocPrf Weight Path
*> 198.51.100.3/32   203.0.113.2          1             0 2 2 2 2 i

Total number of prefixes 1
vyos@vos1:~$
```

You now see the longer AS path.

## Transparent Proxy

The following example will show how VyOS can be used to redirect web traffic to an external transparent proxy:

```
set policy route FILTER-WEB rule 1000 destination port 80
set policy route FILTER-WEB rule 1000 protocol tcp
set policy route FILTER-WEB rule 1000 set table 100
```

This creates a route policy called FILTER-WEB with one rule to set the routing table for matching traffic (TCP port 80) to table ID 100 instead of the default routing table.

To create routing table 100 and add a new default gateway to be used by traffic matching our route policy:

```
set protocols static table 100 route 0.0.0.0/0 next-hop 10.255.0.2
```

This can be confirmed using the `show ip route table 100` operational command.

Finally, to apply the policy route to ingress traffic on our LAN interface, we use:

```
set policy route FILTER-WEB interface eth1
```

## Multiple Uplinks

VyOS Policy-Based Routing (PBR) works by matching source IP address ranges and forwarding the traffic using different routing tables.

Routing tables that will be used in this example are:

- table 10 Routing table used for VLAN 10 (192.168.188.0/24)
- table 11 Routing table used for VLAN 11 (192.168.189.0/24)
- main Routing table used by VyOS and other interfaces not participating in PBR

Add default routes for routing table 10 and table 11

```
set protocols static table 10 route 0.0.0.0/0 next-hop 192.0.1.1
set protocols static table 11 route 0.0.0.0/0 next-hop 192.0.2.2
```

Add policy route matching VLAN source addresses

```
set policy route PBR rule 20 set table '10'
set policy route PBR rule 20 description 'Route VLAN10 traffic to table 10'
set policy route PBR rule 20 source address '192.168.188.0/24'

set policy route PBR rule 30 set table '11'
set policy route PBR rule 30 description 'Route VLAN11 traffic to table 11'
set policy route PBR rule 30 source address '192.168.189.0/24'
```

Apply routing policy to **inbound** direction of out VLAN interfaces

```
set policy route 'PBR' interface eth0.10
set policy route 'PBR' interface eth0.11
```

**OPTIONAL:** Exclude Inter-VLAN traffic (between VLAN10 and VLAN11) from PBR

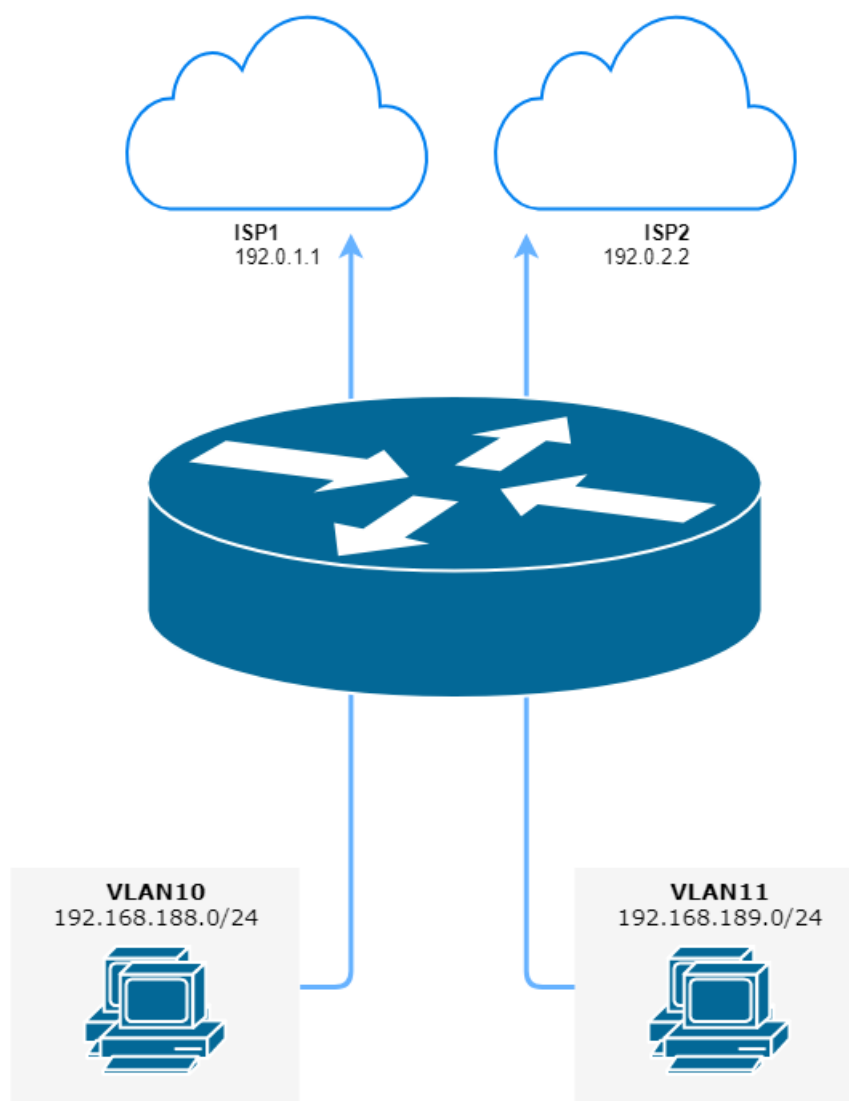

Abb. 2: Policy-Based Routing with multiple ISP uplinks (source ./draw.io/pbr\_example\_1.drawio)

```
set firewall group network-group VLANS-GR description 'VLANs networks'
set firewall group network-group VLANS-GR network '192.168.188.0/24'
set firewall group network-group VLANS-GR network '192.168.189.0/24'

set policy route PBR rule 10 description 'VLAN10 <-> VLAN11 shortcut'
set policy route PBR rule 10 destination group network-group 'VLANS-GR'
set policy route PBR rule 10 set table 'main'
```

These commands allow the VLAN10 and VLAN11 hosts to communicate with each other using the main routing table.

## Local route

The following example allows VyOS to use PBR (Policy-Based Routing) for traffic, which originated from the router itself. That solution for multiple ISP's and VyOS router will respond from the same interface that the packet was received. Also, it used, if we want that one VPN tunnel to be through one provider, and the second through another.

- 203.0.113.254 IP address on VyOS eth1 from ISP1
- 192.168.2.254 IP address on VyOS eth2 from ISP2
- table 10 Routing table used for ISP1
- table 11 Routing table used for ISP2

```
set policy local-route rule 101 set table '10'
set policy local-route rule 101 source '203.0.113.254'
set policy local-route rule 102 set table '11'
set policy local-route rule 102 source '192.0.2.254'
set protocols static table 10 route 0.0.0.0/0 next-hop '203.0.113.1'
set protocols static table 11 route 0.0.0.0/0 next-hop '192.0.2.2'
```

Add multiple source IP in one rule with same priority

```
set policy local-route rule 101 set table '10'
set policy local-route rule 101 source '203.0.113.254'
set policy local-route rule 101 source '203.0.113.253'
set policy local-route rule 101 source '198.51.100.0/24'
```

## Clamp MSS for a specific IP

This example shows how to target an MSS clamp (in our example to 1360 bytes) to a specific destination IP.

```
set policy route IP-MSS-CLAMP rule 10 description 'Clamp TCP session MSS to 1360 for 198.
↪ 51.100.30'
set policy route IP-MSS-CLAMP rule 10 destination address '198.51.100.30/32'
set policy route IP-MSS-CLAMP rule 10 protocol 'tcp'
set policy route IP-MSS-CLAMP rule 10 set tcp-mss '1360'
set policy route IP-MSS-CLAMP rule 10 tcp flags 'SYN'
```

To apply this policy to the correct interface, configure it on the interface the inbound local host will send through to reach our destined target host (in our example eth1).

```
set policy route IP-MSS-CLAMP interface eth1
```

You can view that the policy is being correctly (or incorrectly) utilised with the following command:

```
show policy route statistics
```

## 8.8 PKI

VyOS 1.4 changed the way in how encryption keys or certificates are stored on the system. In the pre VyOS 1.4 era, certificates got stored under /config and every service referenced a file. That made copying a running configuration from system A to system B a bit harder, as you had to copy the files and their permissions by hand.

T3642 describes a new CLI subsystem that serves as a „certstore“ to all services requiring any kind of encryption key(s). In short, public and private certificates are now stored in PKCS#8 format in the regular VyOS CLI. Keys can now be added, edited, and deleted using the regular set/edit/delete CLI commands.

VyOS not only can now manage certificates issued by 3rd party Certificate Authorities, it can also act as a CA on its own. You can create your own root CA and sign keys with it by making use of some simple op-mode commands.

Don't be afraid that you need to re-do your configuration. Key transformation is handled, as always, by our migration scripts, so this will be a smooth transition for you!

### 8.8.1 Key Generation

#### Certificate Authority (CA)

VyOS now also has the ability to create CAs, keys, Diffie-Hellman and other keypairs from an easy to access operational level command.

##### **generate pki ca**

Create a new CA and output the CAs public and private key on the console.

##### **generate pki ca install <name>**

Create a new CA and output the CAs public and private key on the console.

---

**Bemerkung:** In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

---

##### **generate pki ca sign <ca-name>**

Create a new subordinate CA and sign it using the private key referenced by *ca-name*.

##### **generate pki ca sign <ca-name> install <name>**

Create a new subordinate CA and sign it using the private key referenced by *name*.

---

**Bemerkung:** In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

---

## Certificates

### **generate pki certificate**

Create a new public/private keypair and output the certificate on the console.

### **generate pki certificate install <name>**

Create a new public/private keypair and output the certificate on the console.

---

**Bemerkung:** In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

---

### **generate pki certificate self-signed**

Create a new self-signed certificate. The public/private is then shown on the console.

### **generate pki certificate self-signed install <name>**

Create a new self-signed certificate. The public/private is then shown on the console.

---

**Bemerkung:** In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

---

### **generate pki certificate sign <ca-name>**

Create a new public/private keypair which is signed by the CA referenced by *ca-name*. The signed certificate is then output to the console.

### **generate pki certificate sign <ca-name> install <name>**

Create a new public/private keypair which is signed by the CA referenced by *ca-name*. The signed certificate is then output to the console.

---

**Bemerkung:** In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

---

## Diffie-Hellman parameters

### **generate pki dh**

Generate a new set of DH (Diffie-Hellman) parameters. The key size is requested by the CLI and defaults to 2048 bit.

The generated parameters are then output to the console.

### **generate pki dh install <name>**

Generate a new set of DH parameters. The key size is requested by the CLI and defaults to 2048 bit.

---

**Bemerkung:** In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

---

## OpenVPN

### **generate pki openvpn shared-secret**

Generate a new OpenVPN shared secret. The generated secret is the output to the console.

### **generate pki openvpn shared-secret install <name>**

Generate a new OpenVPN shared secret. The generated secret is the output to the console.

---

**Bemerkung:** In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

---

## WireGuard

### **generate pki wireguard key-pair**

Generate a new WireGuard public/private key portion and output the result to the console.

### **generate pki wireguard key-pair install <interface>**

Generate a new WireGuard public/private key portion and output the result to the console.

---

**Bemerkung:** In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

interface is used for the VyOS CLI command to identify the WireGuard interface where this private key is to be used.

---

### **generate pki wireguard preshared-key**

Generate a WireGuard pre-shared secret used for peers to communicate.

### **generate pki wireguard preshared-key install <peer>**

Generate a WireGuard pre-shared secret used for peers to communicate.

---

**Bemerkung:** In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

`peer` is used for the VyOS CLI command to identify the WireGuard peer where this secret is to be used.

---

## 8.8.2 Key usage (CLI)

### CA (Certificate Authority)

#### **set pki ca <name> certificate**

Add the public CA certificate for the CA named *name* to the VyOS CLI.

---

**Bemerkung:** When loading the certificate you need to manually strip the -----BEGIN CERTIFICATE----- and -----END CERTIFICATE----- tags. Also, the certificate/key needs to be presented in a single line without line breaks (\n), this can be done using the following shell command:

```
$ tail -n +2 ca.pem | head -n -1 | tr -d '\n'
```

---

#### **set pki ca <name> crl**

Certificate revocation list in PEM format.

#### **set pki ca <name> description**

A human readable description what this CA is about.

#### **set pki ca <name> private key**

Add the CAs private key to the VyOS CLI. This should never leave the system, and is only required if you use VyOS as your certificate generator as mentioned above.

---

**Bemerkung:** When loading the certificate you need to manually strip the -----BEGIN KEY----- and -----END KEY----- tags. Also, the certificate/key needs to be presented in a single line without line breaks (\n), this can be done using the following shell command:

```
$ tail -n +2 ca.key | head -n -1 | tr -d '\n'
```

---

#### **set pki ca <name> private password-protected**

Mark the CAs private key as password protected. User is asked for the password when the key is referenced.

## Server Certificate

After we have imported the CA certificate(s) we can now import and add certificates used by services on this router.

**set pki certificate <name> certificate**

Add public key portion for the certificate named *name* to the VyOS CLI.

---

**Bemerkung:** When loading the certificate you need to manually strip the -----BEGIN CERTIFICATE----- and -----END CERTIFICATE----- tags. Also, the certificate/key needs to be presented in a single line without line breaks (\n), this can be done using the following shell command:

```
$ tail -n +2 cert.pem | head -n -1 | tr -d '\n'
```

---

**set pki certificate <name> description**

A human readable description what this certificate is about.

**set pki certificate <name> private key**

Add the private key portion of this certificate to the CLI. This should never leave the system as it is used to decrypt the data.

---

**Bemerkung:** When loading the certificate you need to manually strip the -----BEGIN KEY----- and -----END KEY----- tags. Also, the certificate/key needs to be presented in a single line without line breaks (\n), this can be done using the following shell command:

```
$ tail -n +2 cert.key | head -n -1 | tr -d '\n'
```

---

**set pki certificate <name> private password-protected**

Mark the private key as password protected. User is asked for the password when the key is referenced.

**set pki certificate <name> revoke**

If CA is present, this certificate will be included in generated CRLs

## Import files to PKI format

VyOS provides this utility to import existing certificates/key files directly into PKI from op-mode. Previous to VyOS 1.4, certificates were stored under the /config folder permanently and will be retained post upgrade.

**import pki ca <name> file <Path to CA certificate file>**

Import the public CA certificate from the defined file to VyOS CLI.

**import pki ca <name> key-file <Path to private key file>**

Import the CAs private key portion to the CLI. This should never leave the system as it is used to decrypt the data. The key is required if you use VyOS as your certificate generator.

**import pki certificate <name> file <path to certificate>**

Import the certificate from the file to VyOS CLI.

**import pki certificate <name> key-file <path to private key>**

Import the private key of the certificate to the VyOS CLI. This should never leave the system as it is used to decrypt the data.

**import pki openvpn shared-secret <name> file <path to OpenVPN secret key>**

Import the OpenVPN shared secret stored in file to the VyOS CLI.

## ACME

The VyOS PKI subsystem can also be used to automatically retrieve Certificates using the ACME (Automatic Certificate Management Environment) protocol.

**set pki certificate <name> acme domain-name <name>**

Domain names to apply, multiple domain-names can be specified.

This is a mandatory option

**set pki certificate <name> acme email <address>**

Email used for registration and recovery contact.

This is a mandatory option

**set pki certificate <name> acme listen-address <address>**

The address the server listens to during http-01 challenge

**set pki certificate <name> acme rsa-key-size <2048 | 3072 | 4096>**

Size of the RSA key.

This options defaults to 2048

**set pki certificate <name> acme url <url>**

ACME Directory Resource URI.

This defaults to <https://acme-v02.api.letsencrypt.org/directory>

---

**Bemerkung:** During initial deployment we recommend using the staging API of LetsEncrypt to prevent and blacklisting of your system. The API endpoint is <https://acme-staging-v02.api.letsencrypt.org/directory>

---

### 8.8.3 Operation

VyOS operational mode commands are not only available for generating keys but also to display them.

**show pki ca**

Show a list of installed CA certificates.

```
vyos@vyos:~$ show pki ca
Certificate Authorities:
Name          Subject          Issuer CN
-----
→          Issued          Expiry          Private Key    Parent
-----
→-----
DST_Root_CA_X3 CN=ISRG Root X1,0=Internet Security Research Group,C=US CN=DST
→Root CA X3    2021-01-20 19:14:03 2024-09-30 18:14:03 No N/A
R3             CN=R3,0=Let's Encrypt,C=US CN=ISRG
→Root X1      2020-09-04 00:00:00 2025-09-15 16:00:00 No DST_Root_CA_X3
vyos_rw       CN=VyOS RW CA,0=VyOS,L=Some-City,ST=Some-State,C=GB CN=VyOS RW
→CA          2021-07-05 13:46:03 2026-07-04 13:46:03 Yes N/A
```

### show pki ca <name>

Show only information for specified Certificate Authority.

### show pki certificate

Show a list of installed certificates

```
vyos@vyos:~$ show pki certificate
Certificates:
Name          Type      Subject CN          Issuer CN          Issued
→Expiry      Revoked   Private Key        CA Present
-----
→-----
ac2           Server   CN=ac2.vyos.net    CN=R3              2021-07-05 07:29:59  2021-
→10-03 07:29:58 No        Yes                Yes (R3)
rw_server     Server   CN=VyOS RW         CN=VyOS RW CA      2021-07-05 13:48:02  2022-
→07-05 13:48:02 No        Yes                Yes (vyos_rw)
```

### show pki certificate <name>

Show only information for specified certificate.

### show pki crl

Show a list of installed CRLs (Certificate Revocation List).

### renew certbot

Manually trigger certificate renewal. This will be done twice a day.

## 8.8.4 Examples

### Create a CA chain and leaf certificates

This configuration generates & installs into the VyOS PKI system a root certificate authority, alongside two intermediary certificate authorities for client & server certificates. These CAs are then used to generate a server certificate for the router, and a client certificate for a user.

- vyos\_root\_ca is the root certificate authority.
- vyos\_client\_ca and vyos\_server\_ca are intermediary certificate authorities, which are signed by the root CA.
- vyos\_cert is a leaf server certificate used to identify the VyOS router, signed by the server intermediary CA.
- vyos\_example\_user is a leaf client certificate used to identify a user, signed by client intermediary CA.

First, we create the root certificate authority.

```
[edit]
vyos@vyos# run generate pki ca install vyos_root_ca
Enter private key type: [rsa, dsa, ec] (Default: rsa) rsa
Enter private key bits: (Default: 2048) 2048
Enter country code: (Default: GB) GB
Enter state: (Default: Some-State) Some-State
Enter locality: (Default: Some-City) Some-City
Enter organization name: (Default: VyOS) VyOS
Enter common name: (Default: vyos.io) VyOS Root CA
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

Enter how many days certificate will be valid: (Default: 1825) 1825
Note: If you plan to use the generated key on this router, do not encrypt the private_
key.
Do you want to encrypt the private key with a passphrase? [y/N] n
2 value(s) installed. Use "compare" to see the pending changes, and "commit" to apply.

```

Secondly, we create the intermediary certificate authorities, which are used to sign the leaf certificates.

```

[edit]
vyos@vyos# run generate pki ca sign vyos_root_ca install vyos_server_ca
Do you already have a certificate request? [y/N] n
Enter private key type: [rsa, dsa, ec] (Default: rsa) rsa
Enter private key bits: (Default: 2048) 2048
Enter country code: (Default: GB) GB
Enter state: (Default: Some-State) Some-State
Enter locality: (Default: Some-City) Some-City
Enter organization name: (Default: VyOS) VyOS
Enter common name: (Default: vyos.io) VyOS Intermediary Server CA
Enter how many days certificate will be valid: (Default: 1825) 1095
Note: If you plan to use the generated key on this router, do not encrypt the private_
key.
Do you want to encrypt the private key with a passphrase? [y/N] n
2 value(s) installed. Use "compare" to see the pending changes, and "commit" to apply.

```

```

[edit]
vyos@vyos# run generate pki ca sign vyos_root_ca install vyos_client_ca
Do you already have a certificate request? [y/N] n
Enter private key type: [rsa, dsa, ec] (Default: rsa) rsa
Enter private key bits: (Default: 2048) 2048
Enter country code: (Default: GB) GB
Enter state: (Default: Some-State) Some-State
Enter locality: (Default: Some-City) Some-City
Enter organization name: (Default: VyOS) VyOS
Enter common name: (Default: vyos.io) VyOS Intermediary Client CA
Enter how many days certificate will be valid: (Default: 1825) 1095
Note: If you plan to use the generated key on this router, do not encrypt the private_
key.
Do you want to encrypt the private key with a passphrase? [y/N] n
2 value(s) installed. Use "compare" to see the pending changes, and "commit" to apply.

```

Lastly, we can create the leaf certificates that devices and users will utilise.

```

[edit]
vyos@vyos# run generate pki certificate sign vyos_server_ca install vyos_cert

## 8.9 Protocols

### 8.9.1 Babel

Babel is a modern routing protocol designed to be robust and efficient both in ordinary wired networks and in wireless mesh networks. By default, it uses hop-count on wired networks and a variant of ETX on wireless links. It can be configured to take radio diversity into account and to automatically compute a link's latency and include it in the metric. It is defined in [RFC 8966](#).

Babel a dual stack protocol. A single Babel instance is able to perform routing for both IPv4 and IPv6.

## General Configuration

VyOS does not have a special command to start the Babel process. The Babel process starts when the first Babel enabled interface is configured.

**set protocols babel interface <interface>**

This command specifies a Babel enabled interface by interface name. Both the sending and receiving of Babel packets will be enabled on the interface specified in this command.

## Optional Configuration

**set protocols babel parameters diversity**

This command enables routing using radio frequency diversity. This is highly recommended in networks with many wireless nodes.

---

**Bemerkung:** If you enable this, you will probably want to set diversity-factor and channel below.

---

**set protocols babel parameters diversity-factor <1-256>**

This command sets the multiplicative factor used for diversity routing, in units of 1/256; lower values cause diversity to play a more important role in route selection. The default is 256, which means that diversity plays no role in route selection; you will probably want to set that to 128 or less on nodes with multiple independent radios.

**set protocols babel parameters resend-delay <milliseconds>**

This command specifies the time in milliseconds after which an 'important' request or update will be resent. The default is 2000 ms.

**set protocols babel parameters smoothing-half-life <seconds>**

This command specifies the time constant, in seconds, of the smoothing algorithm used for implementing hysteresis. Larger values reduce route oscillation at the cost of very slightly increasing convergence time. The value 0 disables hysteresis, and is suitable for wired networks. The default is 4 s.

## Interfaces Configuration

**set protocols babel interface <interface> type <auto|wired|wireless>**

This command sets the interface type:

**auto** – automatically determines the interface type. **wired** – enables optimisations for wired interfaces. **wireless** – disables a number of optimisations that are only correct on wired interfaces. Specifying wireless is always correct, but may cause slower convergence and extra routing traffic.

**set protocols babel interface <interface> split-horizon <default|disable|enable>**

This command specifies whether to perform split-horizon on the interface. Specifying no babel split-horizon is always correct, while babel split-horizon is an optimisation that should only be used on symmetric and transitive (wired) networks.

**default** – enable split-horizon on wired interfaces, and disable split-horizon on wireless interfaces. **enable** – enable split-horizon on this interfaces. **disable** – disable split-horizon on this interfaces.

**set protocols babel interface <interface> hello-interval <milliseconds>**

This command specifies the time in milliseconds between two scheduled hellos. On wired links, Babel notices a link failure within two hello intervals; on wireless links, the link quality value is reestimated at every hello interval. The default is 4000 ms.

**set protocols babel interface <interface> update-interval <milliseconds>**

This command specifies the time in milliseconds between two scheduled updates. Since Babel makes extensive use of triggered updates, this can be set to fairly high values on links with little packet loss. The default is 20000 ms.

**set protocols babel interface <interface> rxcost <1-65534>**

This command specifies the base receive cost for this interface. For wireless interfaces, it specifies the multiplier used for computing the ETX reception cost (default 256); for wired interfaces, it specifies the cost that will be advertised to neighbours.

**set protocols babel interface <interface> rtt-decay <1-256>**

This command specifies the decay factor for the exponential moving average of RTT samples, in units of 1/256. Higher values discard old samples faster. The default is 42.

**set protocols babel interface <interface> rtt-min <milliseconds>**

This command specifies the minimum RTT, in milliseconds, starting from which we increase the cost to a neighbour. The additional cost is linear in (rtt - rtt-min). The default is 10 ms.

**set protocols babel interface <interface> rtt-max <milliseconds>**

This command specifies the maximum RTT, in milliseconds, above which we don't increase the cost to a neighbour. The default is 120 ms.

**set protocols babel interface <interface> max-rtt-penalty <milliseconds>**

This command specifies the maximum cost added to a neighbour because of RTT, i.e. when the RTT is higher or equal than rtt-max. The default is 150. Setting it to 0 effectively disables the use of a RTT-based cost.

**set protocols babel interface <interface> enable-timestamps**

This command enables sending timestamps with each Hello and IHU message in order to compute RTT values. It is recommended to enable timestamps on tunnel interfaces.

**set protocols babel interface <interface> channel <1-254|interfering|noninterfering>**

This command set the channel number that diversity routing uses for this interface (see diversity option above).

**1-254** – interfaces with a channel number interfere with interfering interfaces and interfaces with the same channel number. **interfering** – interfering interfaces are assumed to interfere with all other channels except noninterfering channels. **noninterfering** – noninterfering interfaces are assumed to only interfere with themselves.

## Redistribution Configuration

**set protocols babel redistribute <ipv4|ipv6> <route source>**

This command redistributes routing information from the given route source to the Babel process.

IPv4 route source: bgp, connected, eigrp, isis, kernel, nhrp, ospf, rip, static.

IPv6 route source: bgp, connected, eigrp, isis, kernel, nhrp, ospfv3, ripng, static.

**set protocols babel distribute-list <ipv4|ipv6> access-list <in|out> <number>**

This command can be used to filter the Babel routes using access lists. in and out this is the direction in which the access lists are applied.

```
set protocols babel distribute-list <ipv4|ipv6> interface <interface> access-list
<in|out> <number>
```

This command allows you apply access lists to a chosen interface to filter the Babel routes.

```
set protocols babel distribute-list <ipv4|ipv6> prefix-list <in|out> <name>
```

This command can be used to filter the Babel routes using prefix lists. in and out this is the direction in which the prefix lists are applied.

```
set protocols babel distribute-list <ipv4|ipv6> interface <interface> prefix-list
<in|out> <name>
```

This command allows you apply prefix lists to a chosen interface to filter the Babel routes.

## Configuration Example

Simple Babel configuration using 2 nodes and redistributing connected interfaces.

### Node 1:

```
set interfaces loopback lo address 10.1.1.1/32
set interfaces loopback lo address fd12:3456:dead:beef::1/128
set protocols babel interface eth0 type wired
set protocols babel redistribute ipv4 connected
set protocols babel redistribute ipv6 connected
```

### Node 2:

```
set interfaces loopback lo address 10.2.2.2/32
set interfaces loopback lo address fd12:3456:beef:dead::2/128
set protocols babel interface eth0 type wired
set protocols babel redistribute ipv4 connected
set protocols babel redistribute ipv6 connected
```

## 8.9.2 BFD

BFD (Bidirectional Forwarding Detection) is described and extended by the following RFCs: [RFC 5880](#), [RFC 5881](#) and [RFC 5883](#).

In the age of very fast networks, a second of unreachability may equal millions of lost packets. The idea behind BFD is to detect very quickly when a peer is down and take action extremely fast.

BFD sends lots of small UDP packets very quickly to ensures that the peer is still alive.

This allows avoiding the timers defined in BGP and OSPF protocol to expires.

## Configure BFD

**set protocols bfd peer <address>**

Set BFD peer IPv4 address or IPv6 address

**set protocols bfd peer <address> echo-mode**

Enables the echo transmission mode

**set protocols bfd peer <address> multihop**

Allow this BFD peer to not be directly connected

**set protocols bfd peer <address> source [address <address> | interface <interface>]**

Bind listener to specific interface/address, mandatory for IPv6

**set protocols bfd peer <address> interval echo-interval <10-60000>**

The minimal echo receive transmission interval that this system is capable of handling

**set protocols bfd peer <address> interval multiplier <2-255>**

Remote transmission interval will be multiplied by this value

**set protocols bfd peer <address> interval [receive | transmit] <10-60000>**

Interval in milliseconds

**set protocols bfd peer <address> shutdown**

Disable a BFD peer

**set protocols bfd peer <address> minimum-ttl <1-254>**

For multi hop sessions only. Configure the minimum expected TTL for an incoming BFD control packet.

This feature serves the purpose of tightening the packet validation requirements to avoid receiving BFD control packets from other sessions.

## Enable BFD in BGP

**set protocols bgp neighbor <neighbor> bfd**

Enable BFD on a single BGP neighbor

**set protocols bgp peer-group <neighbor> bfd**

Enable BFD on a BGP peer group

## Enable BFD in OSPF

**set protocols ospf interface <interface> bfd**

Enable BFD for OSPF on an interface

**set protocols ospfv3 interface <interface> bfd**

Enable BFD for OSPFv3 on an interface

## Enable BFD in ISIS

```
set protocols isis <name> interface <interface> bfd
```

Enable BFD for ISIS on an interface

## Operational Commands

```
show bfd peers
```

Show all BFD peers

```
BFD Peers:
  peer 198.51.100.33 vrf default interface eth4.100
    ID: 4182341893
    Remote ID: 12678929647
    Status: up
    Uptime: 1 month(s), 16 hour(s), 29 minute(s), 38 second(s)
    Diagnostics: ok
    Remote diagnostics: ok
    Local timers:
      Receive interval: 300ms
      Transmission interval: 300ms
      Echo transmission interval: 50ms
    Remote timers:
      Receive interval: 300ms
      Transmission interval: 300ms
      Echo transmission interval: 0ms

  peer 198.51.100.55 vrf default interface eth4.101
    ID: 4618932327
    Remote ID: 3312345688
    Status: up
    Uptime: 20 hour(s), 16 minute(s), 19 second(s)
    Diagnostics: ok
    Remote diagnostics: ok
    Local timers:
      Receive interval: 300ms
      Transmission interval: 300ms
      Echo transmission interval: 50ms
    Remote timers:
      Receive interval: 300ms
      Transmission interval: 300ms
      Echo transmission interval: 0ms
```

## BFD Static Route Monitoring

A monitored static route conditions the installation to the RIB on the BFD session running state: when BFD session is up the route is installed to RIB, but when the BFD session is down it is removed from the RIB.

### Configuration

**set protocols static route <subnet> next-hop <address> bfd profile <profile>**

Configure a static route for <subnet> using gateway <address> and use the gateway address as BFD peer destination address.

**set protocols static route <subnet> next-hop <address> bfd multi-hop source <address> profile <profile>**

Configure a static route for <subnet> using gateway <address> , use source address to identify the peer when is multi-hop session and the gateway address as BFD peer destination address.

**set protocols static route6 <subnet> next-hop <address> bfd profile <profile>**

Configure a static route for <subnet> using gateway <address> and use the gateway address as BFD peer destination address.

**set protocols static route6 <subnet> next-hop <address> bfd multi-hop source <address> profile <profile>**

Configure a static route for <subnet> using gateway <address> , use source address to identify the peer when is multi-hop session and the gateway address as BFD peer destination address.

### Operational Commands

**show bfd static routes**

Showing BFD monitored static routes

Showing BFD monitored static routes:

Next hops:

VRF default IPv4 Unicast:

10.10.13.3/32 peer 192.168.2.3 (status: installed)

172.16.10.3/32 peer 192.168.10.1 (status: uninstalled)

VRF default IPv4 Multicast:

VRF default IPv6 Unicast:

### 8.9.3 BGP

BGP (Border Gateway Protocol) is one of the Exterior Gateway Protocols and the de facto standard interdomain routing protocol. The latest BGP version is 4. BGP-4 is described in [RFC 1771](#) and updated by [RFC 4271](#). [RFC 2858](#) adds multiprotocol support to BGP.

VyOS makes use of FRR (Free Range Routing) and we would like to thank them for their effort!

#### Basic Concepts

##### Autonomous Systems

From [RFC 1930](#):

An AS is a connected group of one or more IP prefixes run by one or more network operators which has a SINGLE and CLEARLY DEFINED routing policy.

Each AS (Autonomous System) has an identifying number associated with it called an ASN (Autonomous System Number). This is a two octet value ranging in value from 1 to 65535. The AS numbers 64512 through 65535 are defined as private AS numbers. Private AS numbers must not be advertised on the global Internet. The 2-byte AS number range has been exhausted. 4-byte AS numbers are specified in [RFC 6793](#), and provide a pool of 4294967296 AS numbers.

The ASN is one of the essential elements of BGP. BGP is a distance vector routing protocol, and the AS-Path framework provides distance vector metric and loop detection to BGP.

**set protocols bgp system-as <asn>**

Set local ASN that this router represents. This is a mandatory option!

##### Address Families

Multiprotocol extensions enable BGP to carry routing information for multiple network layer protocols. BGP supports an Address Family Identifier (AFI) for IPv4 and IPv6.

##### Route Selection

The route selection process used by FRR's BGP implementation uses the following decision criterion, starting at the top of the list and going towards the bottom until one of the factors can be used.

1. **Weight check**

Prefer higher local weight routes to lower routes.

2. **Local preference check**

Prefer higher local preference routes to lower.

3. **Local route check**

Prefer local routes (statics, aggregates, redistributed) to received routes.

4. **AS path length check**

Prefer shortest hop-count AS\_PATHs.

5. **Origin check**

Prefer the lowest origin type route. That is, prefer IGP origin routes to EGP, to Incomplete routes.

#### 6. MED check

Where routes with a MED were received from the same AS, prefer the route with the lowest MED.

#### 7. External check

Prefer the route received from an external, eBGP peer over routes received from other types of peers.

#### 8. IGP cost check

Prefer the route with the lower IGP cost.

#### 9. Multi-path check

If multi-pathing is enabled, then check whether the routes not yet distinguished in preference may be considered equal. If `bgp bestpath as-path multipath-relax` is set, all such routes are considered equal, otherwise routes received via iBGP with identical `AS_PATHs` or routes received from eBGP neighbours in the same AS are considered equal.

#### 10. Already-selected external check

Where both routes were received from eBGP peers, then prefer the route which is already selected. Note that this check is not applied if `bgp bestpath compare-routerid` is configured. This check can prevent some cases of oscillation.

#### 11. Router-ID check

Prefer the route with the lowest *router-ID*. If the route has an *ORIGINATOR\_ID* attribute, through iBGP reflection, then that router ID is used, otherwise the *router-ID* of the peer the route was received from is used.

#### 12. Cluster-List length check

The route with the shortest cluster-list length is used. The cluster-list reflects the iBGP reflection path the route has taken.

#### 13. Peer address

Prefer the route received from the peer with the higher transport layer address, as a last-resort tie-breaker.

## Capability Negotiation

When adding IPv6 routing information exchange feature to BGP. There were some proposals. IETF (Internet Engineering Task Force) IDR (Inter Domain Routing) adopted a proposal called Multiprotocol Extension for BGP. The specification is described in [RFC 2283](#). The protocol does not define new protocols. It defines new attributes to existing BGP. When it is used exchanging IPv6 routing information it is called BGP-4+. When it is used for exchanging multicast routing information it is called MBGP.

*bgpd* supports Multiprotocol Extension for BGP. So if a remote peer supports the protocol, *bgpd* can exchange IPv6 and/or multicast routing information.

Traditional BGP did not have the feature to detect a remote peer's capabilities, e.g. whether it can handle prefix types other than IPv4 unicast routes. This was a big problem using Multiprotocol Extension for BGP in an operational network. [RFC 2842](#) adopted a feature called Capability Negotiation. *bgpd* use this Capability Negotiation to detect the remote peer's capabilities. If a peer is only configured as an IPv4 unicast neighbor, *bgpd* does not send these Capability Negotiation packets (at least not unless other optional BGP features require capability negotiation).

By default, FRR will bring up peering with minimal common capability for the both sides. For example, if the local router has unicast and multicast capabilities and the remote router only has unicast capability the local router will establish the connection with unicast only capability. When there are no common capabilities, FRR sends Unsupported Capability error and then resets the connection.

## Configuration

### BGP Router Configuration

First of all you must configure BGP router with the ASN. The AS number is an identifier for the autonomous system. The BGP protocol uses the AS number for detecting whether the BGP connection is internal or external. VyOS does not have a special command to start the BGP process. The BGP process starts when the first neighbor is configured.

**set protocols bgp system-as <asn>**

Set local autonomous system number that this router represents. This is a mandatory option!

### Peers Configuration

#### Defining Peers

**set protocols bgp neighbor <address|interface> remote-as <asn>**

This command creates a new neighbor whose remote-as is <asn>. The neighbor address can be an IPv4 address or an IPv6 address or an interface to use for the connection. The command is applicable for peer and peer group.

**set protocols bgp neighbor <address|interface> remote-as internal**

Create a peer as you would when you specify an ASN, except that if the peers ASN is different than mine as specified under the protocols bgp <asn> command the connection will be denied.

**set protocols bgp neighbor <address|interface> remote-as external**

Create a peer as you would when you specify an ASN, except that if the peers ASN is the same as mine as specified under the protocols bgp <asn> command the connection will be denied.

**set protocols bgp neighbor <address|interface> local-role <role> [strict]**

BGP roles are defined in RFC [RFC 9234](#) and provide an easy way to add route leak prevention, detection and mitigation. The local Role value is negotiated with the new BGP Role capability which has a built-in check of the corresponding value. In case of a mismatch the new OPEN Roles Mismatch Notification <2, 11> would be sent. The correct Role pairs are:

Provider - Customer

Peer - Peer

RS-Server - RS-Client

If **strict** is set the BGP session won't become established until the BGP neighbor sets local Role on its side. This configuration parameter is defined in RFC [RFC 9234](#) and is used to enforce the corresponding configuration at your counter-parts side.

Routes that are sent from provider, rs-server, or the peer local-role (or if received by customer, rs-client, or the peer local-role) will be marked with a new Only to Customer (OTC) attribute.

Routes with this attribute can only be sent to your neighbor if your local-role is provider or rs-server. Routes with this attribute can be received only if your local-role is customer or rs-client.

In case of peer-peer relationship routes can be received only if OTC value is equal to your neighbor AS number.

All these rules with OTC will help to detect and mitigate route leaks and happen automatically if local-role is set.

**set protocols bgp neighbor <address|interface> shutdown**

This command disable the peer or peer group. To reenale the peer use the delete form of this command.

```
set protocols bgp neighbor <address|interface> description <text>
```

Set description of the peer or peer group.

```
set protocols bgp neighbor <address|interface> update-source <address|interface>
```

Specify the IPv4 source address to use for the BGP session to this neighbor, may be specified as either an IPv4 address directly or as an interface name.

## Capability Negotiation

```
set protocols bgp neighbor <address|interface> capability dynamic
```

This command would allow the dynamic update of capabilities over an established BGP session.

```
set protocols bgp neighbor <address|interface> capability extended-nexthop
```

Allow bgp to negotiate the extended-nexthop capability with it's peer. If you are peering over a IPv6 Link-Local address then this capability is turned on automatically. If you are peering over a IPv6 Global Address then turning on this command will allow BGP to install IPv4 routes with IPv6 nexthops if you do not have IPv4 configured on interfaces.

```
set protocols bgp neighbor <address|interface> disable-capability-negotiation
```

Suppress sending Capability Negotiation as OPEN message optional parameter to the peer. This command only affects the peer is configured other than IPv4 unicast configuration.

When remote peer does not have capability negotiation feature, remote peer will not send any capabilities at all. In that case, bgp configures the peer with configured capabilities.

You may prefer locally configured capabilities more than the negotiated capabilities even though remote peer sends capabilities. If the peer is configured by `override-capability`, VyOS ignores received capabilities then override negotiated capabilities with configured values.

Additionally you should keep in mind that this feature fundamentally disables the ability to use widely deployed BGP features. BGP unnumbered, hostname support, AS4, Addpath, Route Refresh, ORF, Dynamic Capabilities, and graceful restart.

```
set protocols bgp neighbor <address|interface> override-capability
```

This command allow override the result of Capability Negotiation with local configuration. Ignore remote peer's capability value.

```
set protocols bgp neighbor <address|interface> strict-capability-match
```

This command forces strictly compare remote capabilities and local capabilities. If capabilities are different, send Unsupported Capability error then reset connection.

You may want to disable sending Capability Negotiation OPEN message optional parameter to the peer when remote peer does not implement Capability Negotiation. Please use `disable-capability-negotiation` command to disable the feature.

## Peer Parameters

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> allowas-in number <number>**

This command accept incoming routes with AS path containing AS number with the same value as the current system AS. This is used when you want to use the same AS number in your sites, but you can't connect them directly.

The number parameter (1-10) configures the amount of accepted occurrences of the system AS number in AS path.

This command is only allowed for eBGP peers. It is not applicable for peer groups.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> as-override**

This command override AS number of the originating router with the local AS number.

Usually this configuration is used in PEs (Provider Edge) to replace the incoming customer AS number so the connected CE ( Customer Edge) can use the same AS number as the other customer sites. This allows customers of the provider network to use the same AS number across their sites.

This command is only allowed for eBGP peers.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> attribute-unchanged <as-path|med|next-hop>**

This command specifies attributes to be left unchanged for advertisements sent to a peer or peer group.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> maximum-prefix <number>**

This command specifies a maximum number of prefixes we can receive from a given peer. If this number is exceeded, the BGP session will be destroyed. The number range is 1 to 4294967295.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> nexthop-self**

This command forces the BGP speaker to report itself as the next hop for an advertised route it advertised to a neighbor.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> remove-private-as**

This command removes the private ASN of routes that are advertised to the configured peer. It removes only private ASNs on routes advertised to EBGp peers.

If the AS-Path for the route has only private ASNs, the private ASNs are removed.

If the AS-Path for the route has a private ASN between public ASNs, it is assumed that this is a design choice, and the private ASN is not removed.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> soft-reconfiguration inbound**

Changes in BGP policies require the BGP session to be cleared. Clearing has a large negative impact on network operations. Soft reconfiguration enables you to generate inbound updates from a neighbor, change and activate BGP policies without clearing the BGP session.

This command specifies that route updates received from this neighbor will be stored unmodified, regardless of the inbound policy. When inbound soft reconfiguration is enabled, the stored updates are processed by the new policy configuration to create new inbound updates.

---

**Bemerkung:** Storage of route updates uses memory. If you enable soft reconfiguration inbound for multiple neighbors, the amount of memory used can become significant.

---

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> weight <number>**

This command specifies a default weight value for the neighbor's routes. The number range is 1 to 65535.

**set protocols bgp neighbor <address|interface> advertisement-interval <seconds>**

This command specifies the minimum route advertisement interval for the peer. The interval value is 0 to 600 seconds, with the default advertisement interval being 0.

**set protocols bgp neighbor <address|interface> disable-connected-check**

This command allows peerings between directly connected eBGP peers using loopback addresses without adjusting the default TTL of 1.

**set protocols bgp neighbor <address|interface> disable-send-community <extended|standard>**

This command specifies that the community attribute should not be sent in route updates to a peer. By default community attribute is sent.

**set protocols bgp neighbor <address|interface> ebgp-multihop <number>**

This command allows sessions to be established with eBGP neighbors when they are multiple hops away. When the neighbor is not directly connected and this knob is not enabled, the session will not establish. The number of hops range is 1 to 255. This command is mutually exclusive with `ttl-security hops`.

**set protocols bgp neighbor <address|interface> local-as <asn> [no-prepend] [replace-as]**

Specify an alternate AS for this BGP process when interacting with the specified peer or peer group. With no modifiers, the specified local-as is prepended to the received AS\_PATH when receiving routing updates from the peer, and prepended to the outgoing AS\_PATH (after the process local AS) when transmitting local routes to the peer.

If the `no-prepend` attribute is specified, then the supplied local-as is not prepended to the received AS\_PATH.

If the `replace-as` attribute is specified, then only the supplied local-as is prepended to the AS\_PATH when transmitting local-route updates to this peer.

---

**Bemerkung:** This command is only allowed for eBGP peers.

---

**set protocols bgp neighbor <address|interface> passive**

Configures the BGP speaker so that it only accepts inbound connections from, but does not initiate outbound connections to the peer or peer group.

**set protocols bgp neighbor <address|interface> password <text>**

This command specifies a MD5 password to be used with the tcp socket that is being used to connect to the remote peer.

**set protocols bgp neighbor <address|interface> ttl-security hops <number>**

This command enforces Generalized TTL Security Mechanism (GTSM), as specified in [RFC 5082](#). With this command, only neighbors that are specified number of hops away will be allowed to become neighbors. The number of hops range is 1 to 254. This command is mutually exclusive with `ebgp-multihop`.

## Peer Groups

Peer groups are used to help improve scaling by generating the same update information to all members of a peer group. Note that this means that the routes generated by a member of a peer group will be sent back to that originating peer with the originator identifier attribute set to indicated the originating peer. All peers not associated with a specific peer group are treated as belonging to a default peer group, and will share updates.

**set protocols bgp peer-group <name>**

This command defines a new peer group. You can specify to the group the same parameters that you can specify for specific neighbors.

---

**Bemerkung:** If you apply a parameter to an individual neighbor IP address, you override the action defined for a peer group that includes that IP address.

---

**set protocols bgp neighbor <address|interface> peer-group <name>**

This command bind specific peer to peer group with a given name.

## Network Advertisement Configuration

**set protocols bgp address-family <ipv4-unicast|ipv6-unicast> network <prefix>**

This command is used for advertising IPv4 or IPv6 networks.

---

**Bemerkung:** By default, the BGP prefix is advertised even if it's not present in the routing table. This behaviour differs from the implementation of some vendors.

---

**set protocols bgp parameters network-import-check**

This configuration modifies the behavior of the network statement. If you have this configured the underlying network must exist in the routing table.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> default-originate [route-map <name>]**

By default, VyOS does not advertise a default route (0.0.0.0/0) even if it is in routing table. When you want to announce default routes to the peer, use this command. Using optional argument route-map you can inject the default route to given neighbor only if the conditions in the route map are met.

## Route Aggregation Configuration

**set protocols bgp address-family <ipv4-unicast|ipv6-unicast> aggregate-address <prefix>**

This command specifies an aggregate address. The router will also announce longer-prefixes inside of the aggregate address.

**set protocols bgp address-family <ipv4-unicast|ipv6-unicast> aggregate-address <prefix> as-set**

This command specifies an aggregate address with a mathematical set of autonomous systems. This command summarizes the AS\_PATH attributes of all the individual routes.

**set protocols bgp address-family <ipv4-unicast|ipv6-unicast> aggregate-address <prefix> summary-only**

This command specifies an aggregate address and provides that longer-prefixes inside of the aggregate address are suppressed before sending BGP updates out to peers.

```
set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast>
unsuppress-map <name>
```

This command applies route-map to selectively unsuppress prefixes suppressed by summarisation.

## Redistribution Configuration

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> redistribute <route source>
```

This command redistributes routing information from the given route source to the BGP process. There are six modes available for route source: connected, kernel, ospf, rip, static, table.

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> redistribute <route source>
metric <number>
```

This command specifies metric (MED) for redistributed routes. The metric range is 0 to 4294967295. There are six modes available for route source: connected, kernel, ospf, rip, static, table.

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> redistribute <route source>
route-map <name>
```

This command allows to use route map to filter redistributed routes. There are six modes available for route source: connected, kernel, ospf, rip, static, table.

## General Configuration

### Common parameters

```
set protocols bgp parameters allow-martian-nexthop
```

When a peer receives a martian nexthop as part of the NLRI for a route permit the nexthop to be used as such, instead of rejecting and resetting the connection.

```
set protocols bgp parameters router-id <id>
```

This command specifies the router-ID. If router ID is not specified it will use the highest interface IP address.

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> maximum-paths <ebgp|ibgp>
<number>
```

This command defines the maximum number of parallel routes that the BGP can support. In order for BGP to use the second path, the following attributes have to match: Weight, Local Preference, AS Path (both AS number and AS path length), Origin code, MED, IGP metric. Also, the next hop address for each path must be different.

```
set protocols bgp parameters no-hard-administrative-reset
```

Do not send Hard Reset CEASE Notification for „Administrative Reset“ events. When set and Graceful Restart Notification capability is exchanged between the peers, Graceful Restart procedures apply, and routes will be retained.

```
set protocols bgp parameters log-neighbor-changes
```

This command enable logging neighbor up/down changes and reset reason.

```
set protocols bgp parameters no-client-to-client-reflection
```

This command disables route reflection between route reflector clients. By default, the clients of a route reflector are not required to be fully meshed and the routes from a client are reflected to other clients. However, if the clients are fully meshed, route reflection is not required. In this case, use the `no-client-to-client-reflection` command to disable client-to-client reflection.

#### **set protocols bgp parameters no-fast-external-failover**

Disable immediate session reset if peer's connected link goes down.

#### **set protocols bgp listen range <prefix> peer-group <name>**

This command is useful if one desires to loosen the requirement for BGP to have strictly defined neighbors. Specifically what is allowed is for the local router to listen to a range of IPv4 or IPv6 addresses defined by a prefix and to accept BGP open messages. When a TCP connection (and subsequently a BGP open message) from within this range tries to connect the local router then the local router will respond and connect with the parameters that are defined within the peer group. One must define a peer-group for each range that is listed. If no peer-group is defined then an error will keep you from committing the configuration.

#### **set protocols bgp listen limit <number>**

This command goes hand in hand with the listen range command to limit the amount of BGP neighbors that are allowed to connect to the local router. The limit range is 1 to 5000.

#### **set protocols bgp parameters ebgp-requires-policy**

This command changes the eBGP behavior of FRR. By default FRR enables [RFC 8212](#) functionality which affects how eBGP routes are advertised, namely no routes are advertised across eBGP sessions without some sort of egress route-map/policy in place. In VyOS however we have this RFC functionality disabled by default so that we can preserve backwards compatibility with older versions of VyOS. With this option one can enable [RFC 8212](#) functionality to operate.

#### **set protocols bgp parameters labeled-unicast <explicit-null | ipv4-explicit-null | ipv6-explicit-null>**

By default, locally advertised prefixes use the implicit-null label to encode in the outgoing NLRI.

The following command uses the explicit-null label value for all the BGP instances.

### **Administrative Distance**

#### **set protocols bgp parameters distance global <external|internal|local> <distance>**

This command change distance value of BGP. The arguments are the distance values for external routes, internal routes and local routes respectively. The distance range is 1 to 255.

#### **set protocols bgp parameters distance prefix <subnet> distance <distance>**

This command sets the administrative distance for a particular route. The distance range is 1 to 255.

---

**Bemerkung:** Routes with a distance of 255 are effectively disabled and not installed into the kernel.

---

## Timers

### **set protocols bgp timers holdtime <seconds>**

This command specifies hold-time in seconds. The timer range is 4 to 65535. The default value is 180 second. If you set value to 0 VyOS will not hold routes.

### **set protocols bgp timers keepalive <seconds>**

This command specifies keep-alive time in seconds. The timer can range from 4 to 65535. The default value is 60 second.

## Route Dampening

When a route fails, a routing update is sent to withdraw the route from the network's routing tables. When the route is re-enabled, the change in availability is also advertised. A route that continually fails and returns requires a great deal of network traffic to update the network about the route's status.

Route dampening which is described in [RFC 2439](#) enables you to identify routes that repeatedly fail and return. If route dampening is enabled, an unstable route accumulates penalties each time the route fails and returns. If the accumulated penalties exceed a threshold, the route is no longer advertised. This is route suppression. Routes that have been suppressed are re-entered into the routing table only when the amount of their penalty falls below a threshold.

A penalty of 1000 is assessed each time the route fails. When the penalties reach a predefined threshold (suppress-value), the router stops advertising the route.

Once a route is assessed a penalty, the penalty is decreased by half each time a predefined amount of time elapses (half-life-time). When the accumulated penalties fall below a predefined threshold (reuse-value), the route is unsuppressed and added back into the BGP routing table.

No route is suppressed indefinitely. Maximum-suppress-time defines the maximum time a route can be suppressed before it is re-advertised.

### **set protocols bgp parameters dampening half-life <minutes>**

This command defines the amount of time in minutes after which a penalty is reduced by half. The timer range is 10 to 45 minutes.

### **set protocols bgp parameters dampening re-use <seconds>**

This command defines the accumulated penalty amount at which the route is re-advertised. The penalty range is 1 to 20000.

### **set protocols bgp parameters dampening start-suppress-time <seconds>**

This command defines the accumulated penalty amount at which the route is suppressed. The penalty range is 1 to 20000.

### **set protocols bgp parameters dampening max-suppress-time <seconds>**

This command defines the maximum time in minutes that a route is suppressed. The timer range is 1 to 255 minutes.

## Route Selection Configuration

### **set protocols bgp parameters always-compare-med**

This command provides to compare the MED on routes, even when they were received from different neighbouring ASes. Setting this option makes the order of preference of routes more defined, and should eliminate MED induced oscillations.

### **set protocols bgp parameters bestpath as-path confed**

This command specifies that the length of confederation path sets and sequences should be taken into account during the BGP best path decision process.

### **set protocols bgp parameters bestpath as-path multipath-relax**

This command specifies that BGP decision process should consider paths of equal AS\_PATH length candidates for multipath computation. Without the knob, the entire AS\_PATH must match for multipath computation.

### **set protocols bgp parameters bestpath as-path ignore**

Ignore AS\_PATH length when selecting a route

### **set protocols bgp parameters bestpath compare-routerid**

Ensure that when comparing routes where both are equal on most metrics, including local-pref, AS\_PATH length, IGP cost, MED, that the tie is broken based on router-ID.

If this option is enabled, then the already-selected check, where already selected eBGP routes are preferred, is skipped.

If a route has an ORIGINATOR\_ID attribute because it has been reflected, that ORIGINATOR\_ID will be used. Otherwise, the router-ID of the peer the route was received from will be used.

The advantage of this is that the route-selection (at this point) will be more deterministic. The disadvantage is that a few or even one lowest-ID router may attract all traffic to otherwise-equal paths because of this check. It may increase the possibility of MED or IGP oscillation, unless other measures were taken to avoid these. The exact behaviour will be sensitive to the iBGP and reflection topology.

### **set protocols bgp parameters bestpath med confed**

This command specifies that BGP considers the MED when comparing routes originated from different sub-ASs within the confederation to which this BGP speaker belongs. The default state, where the MED attribute is not considered.

### **set protocols bgp parameters bestpath med missing-as-worst**

This command specifies that a route with a MED is always considered to be better than a route without a MED by causing the missing MED attribute to have a value of infinity. The default state, where the missing MED attribute is considered to have a value of zero.

### **set protocols bgp parameters default local-pref <local-pref value>**

This command specifies the default local preference value. The local preference range is 0 to 4294967295.

### **set protocols bgp parameters deterministic-med**

This command provides to compare different MED values that advertised by neighbours in the same AS for routes selection. When this command is enabled, routes from the same autonomous system are grouped together, and the best entries of each group are compared.

### **set protocols bgp address-family ipv4-unicast network <prefix> backdoor**

This command allows the router to prefer route to specified prefix learned via IGP through backdoor link instead of a route to the same prefix learned via EBGp.

## Route Filtering Configuration

In order to control and modify routing information that is exchanged between peers you can use route-map, filter-list, prefix-list, distribute-list.

For inbound updates the order of preference is:

- route-map
- filter-list
- prefix-list, distribute-list

For outbound updates the order of preference is:

- prefix-list, distribute-list
- filter-list
- route-map

---

**Bemerkung:** The attributes `prefix-list` and `distribute-list` are mutually exclusive, and only one command (`distribute-list` or `prefix-list`) can be applied to each inbound or outbound direction for a particular neighbor.

---

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> distribute-list <export|import> <number>**

This command applies the access list filters named in <number> to the specified BGP neighbor to restrict the routing information that BGP learns and/or advertises. The arguments `export` and `import` specify the direction in which the access list are applied.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> prefix-list <export|import> <name>**

This command applies the prefix list filters named in <name> to the specified BGP neighbor to restrict the routing information that BGP learns and/or advertises. The arguments `export` and `import` specify the direction in which the prefix list are applied.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> route-map <export|import> <name>**

This command applies the route map named in <name> to the specified BGP neighbor to control and modify routing information that is exchanged between peers. The arguments `export` and `import` specify the direction in which the route map are applied.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> filter-list <export|import> <name>**

This command applies the AS path access list filters named in <name> to the specified BGP neighbor to restrict the routing information that BGP learns and/or advertises. The arguments `export` and `import` specify the direction in which the AS path access list are applied.

**set protocols bgp neighbor <address|interface> address-family <ipv4-unicast|ipv6-unicast> capability orf <receive|send>**

This command enables the ORF capability (described in [RFC 5291](#)) on the local router, and enables ORF capability advertisement to the specified BGP peer. The `receive` keyword configures a router to advertise ORF receive capabilities. The `send` keyword configures a router to advertise ORF send capabilities. To advertise a filter from a sender, you must create an IP prefix list for the specified BGP peer applied in inbound direction.

**set protocols bgp neighbor <address|interface> solo**

This command prevents from sending back prefixes learned from the neighbor.

## BGP Scaling Configuration

BGP routers connected inside the same AS through BGP belong to an internal BGP session, or IBGP. In order to prevent routing table loops, IBGP speaker does not advertise IBGP-learned routes to other IBGP speaker (Split Horizon mechanism). As such, IBGP requires a full mesh of all peers. For large networks, this quickly becomes unscalable.

There are two ways that help us to mitigate the BGP's full-mesh requirement in a network:

- Using BGP route-reflectors
- Using BGP confederation

## Route Reflector Configuration

Introducing route reflectors removes the need for the full-mesh. When you configure a route reflector you have to tell the router whether the other IBGP router is a client or non-client. A client is an IBGP router that the route reflector will “reflect” routes to, the non-client is just a regular IBGP neighbor. Route reflectors mechanism is described in [RFC 4456](#) and updated by [RFC 7606](#).

```
set protocols bgp neighbor <address> address-family <ipv4-unicast|ipv6-unicast>  
route-reflector-client
```

This command specifies the given neighbor as route reflector client.

```
set protocols bgp parameters cluster-id <id>
```

This command specifies cluster ID which identifies a collection of route reflectors and their clients, and is used by route reflectors to avoid looping. By default cluster ID is set to the BGP router id value, but can be set to an arbitrary 32-bit value.

## Confederation Configuration

A BGP confederation divides our AS into sub-ASes to reduce the number of required IBGP peerings. Within a sub-AS we still require full-mesh IBGP but between these sub-ASes we use something that looks like EBGP but behaves like IBGP (called confederation BGP). Confederation mechanism is described in [RFC 5065](#)

```
set protocols bgp parameters confederation identifier <asn>
```

This command specifies a BGP confederation identifier. <asn> is the number of the autonomous system that internally includes multiple sub-autonomous systems (a confederation).

```
set protocols bgp parameters confederation peers <nsubasn>
```

This command sets other confederations <nsubasn> as members of autonomous system specified by confederation identifier <asn>.

## Operational Mode Commands

### Show

#### **show bgp <ipv4|ipv6>**

This command displays all entries in BGP routing table.

```
BGP table version is 10, local router ID is 10.0.35.3, vrf id 0
Default local pref 100, local AS 65000
Status codes: s suppressed, d damped, h history, * valid, > best, = multipath,
               i internal, r RIB-failure, S Stale, R Removed
Nexthop codes: @NNN nexthop's vrf id, < announce-nh-self
Origin codes: i - IGP, e - EGP, ? - incomplete
RPKI validation codes: V valid, I invalid, N Not found
```

Network	Next Hop	Metric	LocPrf	Weight	Path
*> 198.51.100.0/24	10.0.34.4	0		0	65004 i
*> 203.0.113.0/24	10.0.35.5	0		0	65005 i

Displayed 2 routes and 2 total paths

#### **show bgp <ipv4|ipv6> <address|prefix>**

This command displays information about the particular entry in the BGP routing table.

```
BGP routing table entry for 198.51.100.0/24
Paths: (1 available, best #1, table default)
  Advertised to non peer-group peers:
    10.0.13.1 10.0.23.2 10.0.34.4 10.0.35.5
  65004
    10.0.34.4 from 10.0.34.4 (10.0.34.4)
      Origin IGP, metric 0, valid, external, best (First path received)
      Last update: Wed Jan  6 12:18:53 2021
```

#### **show ip bgp cidr-only**

This command displays routes with classless interdomain routing (CIDR).

#### **show bgp <ipv4|ipv6> community <value>**

This command displays routes that belong to specified BGP communities. Valid value is a community number in the range from 1 to 4294967200, or AA:NN (autonomous system-community number/2-byte number), no-export, local-as, or no-advertise.

#### **show bgp <ipv4|ipv6> community-list <name>**

This command displays routes that are permitted by the BGP community list.

#### **show bgp <ipv4|ipv6> dampening dampened-paths**

This command displays BGP dampened routes.

#### **show bgp <ipv4|ipv6> dampening flap-statistics**

This command displays information about flapping BGP routes.

#### **show bgp <ipv4|ipv6> filter-list <name>**

This command displays BGP routes allowed by the specified AS Path access list.

**show bgp <ipv4|ipv6> neighbors <address> advertised-routes**

This command displays BGP routes advertised to a neighbor.

**show bgp <ipv4|ipv6> neighbors <address> received-routes**

This command displays BGP routes originating from the specified BGP neighbor before inbound policy is applied. To use this command inbound soft reconfiguration must be enabled.

**show bgp <ipv4|ipv6> neighbors <address> routes**

This command displays BGP received-routes that are accepted after filtering.

**show bgp <ipv4|ipv6> neighbors <address> dampened-routes**

This command displays dampened routes received from BGP neighbor.

**show bgp <ipv4|ipv6> regexp <text>**

This command displays information about BGP routes whose AS path matches the specified regular expression.

**show bgp <ipv4|ipv6> summary**

This command displays the status of all BGP connections.

```
IPv4 Unicast Summary:
BGP router identifier 10.0.35.3, local AS number 65000 vrf-id 0
BGP table version 11
RIB entries 5, using 920 bytes of memory
Peers 4, using 82 KiB of memory
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
10.0.13.1	4	65000	148	159	0	0	0	02:16:01	0
10.0.23.2	4	65000	136	143	0	0	0	02:13:21	0
10.0.34.4	4	65004	161	163	0	0	0	02:16:01	1
10.0.35.5	4	65005	162	166	0	0	0	02:16:01	1

```
Total number of neighbors 4
```

## Reset

**reset <ip|ipv6> bgp <address> [soft [in|out]]**

This command resets BGP connections to the specified neighbor IP address. With argument **soft** this command initiates a soft reset. If you do not specify the **in** or **out** options, both inbound and outbound soft reconfiguration are triggered.

**reset ip bgp all**

This command resets all BGP connections of given router.

**reset ip bgp dampening**

This command uses to clear BGP route dampening information and to unsuppress suppressed routes.

**reset ip bgp external**

This command resets all external BGP peers of given router.

**reset ip bgp peer-group <name> [soft [in|out]]**

This command resets BGP connections to the specified peer group. With argument `soft` this command initiates a soft reset. If you do not specify the `in` or `out` options, both inbound and outbound soft reconfiguration are triggered.

## Examples

### IPv4 peering

A simple eBGP configuration:

#### Node 1:

```
set protocols bgp system-as 65534
set protocols bgp neighbor 192.168.0.2 ebgp-multihop '2'
set protocols bgp neighbor 192.168.0.2 remote-as '65535'
set protocols bgp neighbor 192.168.0.2 update-source '192.168.0.1'
set protocols bgp address-family ipv4-unicast network '172.16.0.0/16'
set protocols bgp parameters router-id '192.168.0.1'
```

#### Node 2:

```
set protocols bgp system-as 65535
set protocols bgp neighbor 192.168.0.1 ebgp-multihop '2'
set protocols bgp neighbor 192.168.0.1 remote-as '65534'
set protocols bgp neighbor 192.168.0.1 update-source '192.168.0.2'
set protocols bgp address-family ipv4-unicast network '172.17.0.0/16'
set protocols bgp parameters router-id '192.168.0.2'
```

Don't forget, the CIDR declared in the network statement **MUST exist in your routing table (dynamic or static)**, the **best way to make sure that is true is creating a static route**:

#### Node 1:

```
set protocols static route 172.16.0.0/16 blackhole distance '254'
```

#### Node 2:

```
set protocols static route 172.17.0.0/16 blackhole distance '254'
```

### IPv6 peering

A simple BGP configuration via IPv6.

#### Node 1:

```
set protocols bgp system-as 65534
set protocols bgp neighbor 2001:db8::2 ebgp-multihop '2'
set protocols bgp neighbor 2001:db8::2 remote-as '65535'
set protocols bgp neighbor 2001:db8::2 update-source '2001:db8::1'
set protocols bgp neighbor 2001:db8::2 address-family ipv6-unicast
set protocols bgp address-family ipv6-unicast network '2001:db8:1::/48'
set protocols bgp parameters router-id '10.1.1.1'
```

#### Node 2:

```
set protocols bgp system-as 65535
set protocols bgp neighbor 2001:db8::1 ebgp-multihop '2'
set protocols bgp neighbor 2001:db8::1 remote-as '65534'
set protocols bgp neighbor 2001:db8::1 update-source '2001:db8::2'
set protocols bgp neighbor 2001:db8::1 address-family ipv6-unicast
set protocols bgp address-family ipv6-unicast network '2001:db8:2::/48'
set protocols bgp parameters router-id '10.1.1.2'
```

Don't forget, the CIDR declared in the network statement **MUST** exist in your routing table (dynamic or static), the best way to make sure that is true is creating a static route:

**Node 1:**

```
set protocols static route6 2001:db8:1::/48 blackhole distance '254'
```

**Node 2:**

```
set protocols static route6 2001:db8:2::/48 blackhole distance '254'
```

## Route Filtering

Route filter can be applied using a route-map:

**Node1:**

```
set policy prefix-list AS65535-IN rule 10 action 'permit'
set policy prefix-list AS65535-IN rule 10 prefix '172.16.0.0/16'
set policy prefix-list AS65535-OUT rule 10 action 'deny'
set policy prefix-list AS65535-OUT rule 10 prefix '172.16.0.0/16'
set policy prefix-list6 AS65535-IN rule 10 action 'permit'
set policy prefix-list6 AS65535-IN rule 10 prefix '2001:db8:2::/48'
set policy prefix-list6 AS65535-OUT rule 10 action 'deny'
set policy prefix-list6 AS65535-OUT rule 10 prefix '2001:db8:2::/48'

set policy route-map AS65535-IN rule 10 action 'permit'
set policy route-map AS65535-IN rule 10 match ip address prefix-list 'AS65535-IN'
set policy route-map AS65535-IN rule 10 match ipv6 address prefix-list 'AS65535-IN'
set policy route-map AS65535-IN rule 20 action 'deny'
set policy route-map AS65535-OUT rule 10 action 'deny'
set policy route-map AS65535-OUT rule 10 match ip address prefix-list 'AS65535-OUT'
set policy route-map AS65535-OUT rule 10 match ipv6 address prefix-list 'AS65535-OUT'
set policy route-map AS65535-OUT rule 20 action 'permit'

set protocols bgp system-as 65534
set protocols bgp neighbor 2001:db8::2 address-family ipv4-unicast route-map export
↪ 'AS65535-OUT'
set protocols bgp neighbor 2001:db8::2 address-family ipv4-unicast route-map import
↪ 'AS65535-IN'
set protocols bgp neighbor 2001:db8::2 address-family ipv6-unicast route-map export
↪ 'AS65535-OUT'
set protocols bgp neighbor 2001:db8::2 address-family ipv6-unicast route-map import
↪ 'AS65535-IN'
```

**Node2:**

```

set policy prefix-list AS65534-IN rule 10 action 'permit'
set policy prefix-list AS65534-IN rule 10 prefix '172.17.0.0/16'
set policy prefix-list AS65534-OUT rule 10 action 'deny'
set policy prefix-list AS65534-OUT rule 10 prefix '172.17.0.0/16'
set policy prefix-list6 AS65534-IN rule 10 action 'permit'
set policy prefix-list6 AS65534-IN rule 10 prefix '2001:db8:1::/48'
set policy prefix-list6 AS65534-OUT rule 10 action 'deny'
set policy prefix-list6 AS65534-OUT rule 10 prefix '2001:db8:1::/48'

set policy route-map AS65534-IN rule 10 action 'permit'
set policy route-map AS65534-IN rule 10 match ip address prefix-list 'AS65534-IN'
set policy route-map AS65534-IN rule 10 match ipv6 address prefix-list 'AS65534-IN'
set policy route-map AS65534-IN rule 20 action 'deny'
set policy route-map AS65534-OUT rule 10 action 'deny'
set policy route-map AS65534-OUT rule 10 match ip address prefix-list 'AS65534-OUT'
set policy route-map AS65534-OUT rule 10 match ipv6 address prefix-list 'AS65534-OUT'
set policy route-map AS65534-OUT rule 20 action 'permit'

set protocols bgp system-as 65535
set protocols bgp neighbor 2001:db8::1 address-family ipv4-unicast route-map export
↪ 'AS65534-OUT'
set protocols bgp neighbor 2001:db8::1 address-family ipv4-unicast route-map import
↪ 'AS65534-IN'
set protocols bgp neighbor 2001:db8::1 address-family ipv6-unicast route-map export
↪ 'AS65534-OUT'
set protocols bgp neighbor 2001:db8::1 address-family ipv6-unicast route-map import
↪ 'AS65534-IN'

```

We could expand on this and also deny link local and multicast in the rule 20 action deny.

## 8.9.4 Failover

Failover routes are manually configured routes, but they only install to the routing table if the health-check target is alive. If the target is not alive the route is removed from the routing table until the target becomes available.

### Failover Routes

**set protocols failover route <subnet> next-hop <address> check target <target-address>**

Configure next-hop <address> and <target-address> for an IPv4 static route. Specify the target IPv4 address for health checking.

**set protocols failover route <subnet> next-hop <address> check timeout <timeout>**

Timeout in seconds between health target checks.

Range is 1 to 300, default is 10.

**set protocols failover route <subnet> next-hop <address> check type <protocol>**

Defines protocols for checking ARP, ICMP, TCP

Default is icmp.

**set protocols failover route <subnet> next-hop <address> check policy <policy>**

Policy for checking targets

- **all-available** all checking target addresses must be available to pass this check
- **any-available** any of the checking target addresses must be available to pass this check

Default is any-available.

**set protocols failover route <subnet> next-hop <address> interface <interface>**

Next-hop interface for the route

**set protocols failover route <subnet> next-hop <address> metric <metric>**

Route metric

Default 1.

## Example

### One gateway:

```
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 check target '192.0.2.1'
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 check timeout '5'
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 check type 'icmp'
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 interface 'eth0'
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 metric '10'
```

Show the route

```
vyos@vyos:~$ show ip route 203.0.113.1
Routing entry for 203.0.113.1/32
Known via "kernel", distance 0, metric 10, best
Last update 00:00:39 ago
* 192.0.2.1, via eth0
```

### Two gateways and different metrics:

```
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 check target '192.0.2.1'
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 check timeout '5'
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 check type 'icmp'
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 interface 'eth0'
set protocols failover route 203.0.113.1/32 next-hop 192.0.2.1 metric '10'

set protocols failover route 203.0.113.1/32 next-hop 198.51.100.1 check target '198.51.
→100.99'
set protocols failover route 203.0.113.1/32 next-hop 198.51.100.1 check timeout '5'
set protocols failover route 203.0.113.1/32 next-hop 198.51.100.1 check type 'icmp'
set protocols failover route 203.0.113.1/32 next-hop 198.51.100.1 interface 'eth2'
set protocols failover route 203.0.113.1/32 next-hop 198.51.100.1 metric '20'
```

Show the route

```
vyos@vyos:~$ show ip route 203.0.113.1
Routing entry for 203.0.113.1/32
Known via "kernel", distance 0, metric 10, best
Last update 00:08:06 ago
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
* 192.0.2.1, via eth0

Routing entry for 203.0.113.1/32
  Known via "kernel", distance 0, metric 20
  Last update 00:08:14 ago
* 198.51.100.1, via eth2
```

## 8.9.5 IGMP Proxy

IGMP (Internet Group Management Protocol) proxy sends IGMP host messages on behalf of a connected client. The configuration must define one, and only one upstream interface, and one or more downstream interfaces.

### Configuration

**set protocols igmp-proxy interface <interface> role <upstream | downstream>**

- **upstream:** The upstream network interface is the outgoing interface which is responsible for communicating to available multicast data sources. There can only be one upstream interface.
- **downstream:** Downstream network interfaces are the distribution interfaces to the destination networks, where multicast clients can join groups and receive multicast data. One or more downstream interfaces must be configured.

**set protocols igmp-proxy interface <interface> alt-subnet <network>**

Defines alternate sources for multicasting and IGMP data. The network address must be on the following format 'a.b.c.d/n'. By default, the router will accept data from sources on the same network as configured on an interface. If the multicast source lies on a remote network, one must define from where traffic should be accepted.

This is especially useful for the upstream interface, since the source for multicast traffic is often from a remote location.

This option can be supplied multiple times.

**set protocols igmp-proxy disable-quickleave**

Disables quickleave mode. In this mode the daemon will not send a Leave IGMP message upstream as soon as it receives a Leave message for any downstream interface. The daemon will not ask for Membership reports on the downstream interfaces, and if a report is received the group is not joined again the upstream.

If it's vital that the daemon should act exactly like a real multicast client on the upstream interface, this function should be enabled.

Enabling this function increases the risk of bandwidth saturation.

**set protocols igmp-proxy disable**

Disable this service.

## Example

Interface *eth1* LAN is behind NAT. In order to subscribe *10.0.0.0/23* subnet multicast which is in *eth0* WAN we need to configure igmp-proxy.

```
set protocols igmp-proxy interface eth0 role upstream
set protocols igmp-proxy interface eth0 alt-subnet 10.0.0.0/23
set protocols igmp-proxy interface eth1 role downstream
```

## Operation

### restart igmp-proxy

Restart the IGMP proxy process.

## 8.9.6 IS-IS

IS-IS (Intermediate System to Intermediate System) is a link-state interior gateway protocol (IGP) which is described in ISO10589, [RFC 1195](#), [RFC 5308](#). IS-IS runs the Dijkstra shortest-path first (SPF) algorithm to create a database of the network's topology, and from that database to determine the best (that is, lowest cost) path to a destination. The intermediate systems (the name for routers) exchange topology information with their directly connected neighbors. IS-IS runs directly on the data link layer (Layer 2). IS-IS addresses are called NETs (Network Entity Titles) and can be 8 to 20 bytes long, but are generally 10 bytes long. The tree database that is created with IS-IS is similar to the one that is created with OSPF in that the paths chosen should be similar. Comparisons to OSPF are inevitable and often are reasonable ones to make in regards to the way a network will respond with either IGP.

## General

## Configuration

### Mandatory Settings

For IS-IS top operate correctly, one must do the equivalent of a Router ID in CLNS. This Router ID is called the NET (Network Entity Title). This must be unique for each and every router that is operating in IS-IS. It also must not be duplicated otherwise the same issues that occur within OSPF will occur within IS-IS when it comes to said duplication.

**set protocols isis net <network-entity-title>**

This command sets network entity title (NET) provided in ISO format.

Here is an example NET value:

```
49.0001.1921.6800.1002.00
```

The CLNS address consists of the following parts:

- AFI (Address family authority identifier) - 49 The AFI value 49 is what IS-IS uses for private addressing.
- Area identifier: 0001 IS-IS area number (numerical area 1)
- System identifier: 1921.6800.1002 - for system identifiers we recommend to use IP address or MAC address of the router itself. The way to construct this is to keep all of the zeroes of the router IP address, and then change the periods from being every three numbers to every four numbers. The address that is

listed here is 192.168.1.2, which if expanded will turn into 192.168.001.002. Then all one has to do is move the dots to have four numbers instead of three. This gives us 1921.6800.1002.

- **NET selector:** 00 Must always be 00. This setting indicates „this system“ or „local system.“

#### **set protocols isis interface <interface>**

This command enables IS-IS on this interface, and allows for adjacency to occur. Note that the name of IS-IS instance must be the same as the one used to configure the IS-IS process.

### **IS-IS Global Configuration**

#### **set protocols isis dynamic-hostname**

This command enables support for dynamic hostname TLV. Dynamic hostname mapping determined as described in [RFC 2763](#), Dynamic Hostname Exchange Mechanism for IS-IS.

#### **set protocols isis level <level-1|level-1-2|level-2>**

This command defines the IS-IS router behavior:

- **level-1** - Act as a station (Level 1) router only.
- **level-1-2** - Act as a station (Level 1) router and area (Level 2) router.
- **level-2-only** - Act as an area (Level 2) router only.

#### **set protocols isis lsp-mtu <size>**

This command configures the maximum size of generated LSPs (Link State PDUs), in bytes. The size range is 128 to 4352.

#### **set protocols isis metric-style <narrow|transition|wide>**

This command sets old-style (ISO 10589) or new style packet formats:

- **narrow** - Use old style of TLVs with narrow metric.
- **transition** - Send and accept both styles of TLVs during transition.
- **wide** - Use new style of TLVs to carry wider metric.

#### **set protocols isis purge-originator**

This command enables [RFC 6232](#) purge originator identification. Enable purge originator identification (POI) by adding the type, length and value (TLV) with the Intermediate System (IS) identification to the LSPs that do not contain POI information. If an IS generates a purge, VyOS adds this TLV with the system ID of the IS to the purge.

#### **set protocols isis set-attached-bit**

This command sets ATT bit to 1 in Level1 LSPs. It is described in [RFC 3787](#).

#### **set protocols isis set-overload-bit**

This command sets overload bit to avoid any transit traffic through this router. It is described in [RFC 3787](#).

#### **set protocols isis name default-information originate <ipv4|ipv6> level-1**

This command will generate a default-route in L1 database.

#### **set protocols isis name default-information originate <ipv4|ipv6> level-2**

This command will generate a default-route in L2 database.

#### **set protocols isis ldp-sync**

This command will enable IGP-LDP synchronization globally for ISIS. This requires for LDP to be functional. This is described in [RFC 5443](#). By default all interfaces operational in IS-IS are enabled for synchronization. Loopbacks are exempt.

**set protocols isis ldp-sync holddown <seconds>**

This command will change the hold down value globally for IGP-LDP synchronization during convergence/interface flap events.

## Interface Configuration

**set protocols isis interface <interface> circuit-type <level-1|level-1-2|level-2-only>**

This command specifies circuit type for interface:

- **level-1** - Level-1 only adjacencies are formed.
- **level-1-2** - Level-1-2 adjacencies are formed
- **level-2-only** - Level-2 only adjacencies are formed

**set protocols isis interface <interface> hello-interval <seconds>**

This command sets hello interval in seconds on a given interface. The range is 1 to 600.

**set protocols isis interface <interface> hello-multiplier <seconds>**

This command sets multiplier for hello holding time on a given interface. The range is 2 to 100.

**set protocols isis interface <interface> hello-padding**

This command configures padding on hello packets to accommodate asymmetrical maximum transfer units (MTUs) from different hosts as described in [RFC 3719](#). This helps to prevent a premature adjacency Up state when one routing devices MTU does not meet the requirements to establish the adjacency.

**set protocols isis interface <interface> metric <metric>**

This command set default metric for circuit.

The metric range is 1 to 16777215 (Max value depend if metric support narrow or wide value).

**set protocols isis interface <interface> network point-to-point**

This command specifies network type to Point-to-Point. The default network type is broadcast.

**set protocols isis interface <interface> passive**

This command configures the passive mode for this interface.

**set protocols isis interface <interface> password plaintext-password <text>**

This command configures the authentication password for the interface.

**set protocols isis interface <interface> priority <number>**

This command sets priority for the interface for DIS (Designated Intermediate System) election. The priority range is 0 to 127.

**set protocols isis interface <interface> psnp-interval <number>**

This command sets PSNP interval in seconds. The interval range is 0 to 127.

**set protocols isis interface <interface> no-three-way-handshake**

This command disables Three-Way Handshake for P2P adjacencies which described in [RFC 5303](#). Three-Way Handshake is enabled by default.

**set protocols isis interface <interface> ldp-sync disable**

This command disables IGP-LDP sync for this specific interface.

**set protocols isis interface <interface> ldp-sync holddown <seconds>**

This command will change the hold down value for IGP-LDP synchronization during convergence/interface flap events, but for this interface only.

## Route Redistribution

**set protocols isis redistribute ipv4 <route source> level-1**

This command redistributes routing information from the given route source into the ISIS database as Level-1. There are six modes available for route source: bgp, connected, kernel, ospf, rip, static.

**set protocols isis redistribute ipv4 <route source> level-2**

This command redistributes routing information from the given route source into the ISIS database as Level-2. There are six modes available for route source: bgp, connected, kernel, ospf, rip, static.

**set protocols isis redistribute ipv4 <route source> <level-1|level-2> metric <number>**

This command specifies metric for redistributed routes from the given route source. There are six modes available for route source: bgp, connected, kernel, ospf, rip, static. The metric range is 1 to 16777215.

**set protocols isis redistribute ipv4 <route source> <level-1|level-2> route-map <name>**

This command allows to use route map to filter redistributed routes from the given route source. There are six modes available for route source: bgp, connected, kernel, ospf, rip, static.

## Timers

**set protocols isis lsp-gen-interval <seconds>**

This command sets minimum interval in seconds between regenerating same LSP. The interval range is 1 to 120.

**set protocols isis lsp-refresh-interval <seconds>**

This command sets LSP refresh interval in seconds. IS-IS generates LSPs when the state of a link changes. However, to ensure that routing databases on all routers remain converged, LSPs in stable networks are generated on a regular basis even though there has been no change to the state of the links. The interval range is 1 to 65235. The default value is 900 seconds.

**set protocols isis max-lsp-lifetime <seconds>**

This command sets LSP maximum LSP lifetime in seconds. The interval range is 350 to 65535. LSPs remain in a database for 1200 seconds by default. If they are not refreshed by that time, they are deleted. You can change the LSP refresh interval or the LSP lifetime. The LSP refresh interval should be less than the LSP lifetime or else LSPs will time out before they are refreshed.

**set protocols isis spf-interval <seconds>**

This command sets minimum interval between consecutive SPF calculations in seconds. The interval range is 1 to 120.

**set protocols isis spf-delay-ietf holddown <milliseconds>**

**set protocols isis spf-delay-ietf init-delay <milliseconds>**

**set protocols isis spf-delay-ietf long-delay <milliseconds>**

```
set protocols isis spf-delay-ietf short-delay <milliseconds>
```

```
set protocols isis spf-delay-ietf time-to-learn <milliseconds>
```

This commands specifies the Finite State Machine (FSM) intended to control the timing of the execution of SPF calculations in response to IGP events. The process described in [RFC 8405](#).

### Loop Free Alternate (LFA)

```
set protocols isis fast-reroute lfa remote prefix-list <name> <level-1|level-2>
```

This command enables IP fast re-routing that is part of [RFC 5286](#). Specifically this is a prefix list which references a prefix in which will select eligible PQ nodes for remote LFA backups.

```
set protocols isis fast-reroute lfa local load-sharing disable <level-1|level-2>
```

This command disables the load sharing across multiple LFA backups.

```
set protocols isis fast-reroute lfa local tiebreaker <downstream|lowest-backup-metric|node-protecting>  
index <number> <level-1|level-2>
```

This command will configure a tie-breaker for multiple local LFA backups. The lower index numbers will be processed first.

```
set protocols isis fast-reroute lfa local priority-limit <medium|high|critical>  
<level-1|level-2>
```

This command will limit LFA backup computation up to the specified prefix priority.

### Examples

#### Enable IS-IS

##### Node 1:

```
set interfaces loopback lo address '192.168.255.255/32'  
set interfaces ethernet eth1 address '192.0.2.1/24'  
  
set protocols isis interface eth1  
set protocols isis interface lo  
set protocols isis net '49.0001.1921.6825.5255.00'
```

##### Node 2:

```
set interfaces ethernet eth1 address '192.0.2.2/24'  
  
set interfaces loopback lo address '192.168.255.254/32'  
set interfaces ethernet eth1 address '192.0.2.2/24'  
  
set protocols isis interface eth1  
set protocols isis interface lo  
set protocols isis net '49.0001.1921.6825.5254.00'
```

This gives us the following neighborships, Level 1 and Level 2:

```
Node-1@vyos:~$ show isis neighbor
Area VyOS:
  System Id      Interface  L  State      Holdtime SNPA
vyos             eth1       1  Up         28        0c87.6c09.0001
vyos             eth1       2  Up         28        0c87.6c09.0001

Node-2@vyos:~$ show isis neighbor
Area VyOS:
  System Id      Interface  L  State      Holdtime SNPA
vyos             eth1       1  Up         29        0c33.0280.0001
vyos             eth1       2  Up         28        0c33.0280.0001
```

Here's the IP routes that are populated. Just the loopback:

```
Node-1@vyos:~$ show ip route isis
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, F - PBR,
       f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup
       t - trapped, o - offload failure

I   192.0.2.0/24 [115/20] via 192.0.2.2, eth1 inactive, weight 1, 00:02:22
I>* 192.168.255.254/32 [115/20] via 192.0.2.2, eth1, weight 1, 00:02:22

Node-2@vyos:~$ show ip route isis
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, F - PBR,
       f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup
       t - trapped, o - offload failure

I   192.0.2.0/24 [115/20] via 192.0.2.1, eth1 inactive, weight 1, 00:02:21
I>* 192.168.255.255/32 [115/20] via 192.0.2.1, eth1, weight 1, 00:02:21
```

## Enable IS-IS and redistribute routes not natively in IS-IS

### Node 1:

```
set interfaces dummy dum0 address '203.0.113.1/24'
set interfaces ethernet eth1 address '192.0.2.1/24'

set policy prefix-list EXPORT-ISIS rule 10 action 'permit'
set policy prefix-list EXPORT-ISIS rule 10 prefix '203.0.113.0/24'
set policy route-map EXPORT-ISIS rule 10 action 'permit'
set policy route-map EXPORT-ISIS rule 10 match ip address prefix-list 'EXPORT-ISIS'

set protocols isis interface eth1
set protocols isis net '49.0001.1921.6800.1002.00'
set protocols isis redistribute ipv4 connected level-2 route-map 'EXPORT-ISIS'
```

**Node 2:**

```
set interfaces ethernet eth1 address '192.0.2.2/24'

set protocols isis interface eth1
set protocols isis net '49.0001.1921.6800.2002.00'
```

Routes on Node 2:

```
Node-2@r2:~$ show ip route isis
Codes: K - kernel route, C - connected, S - static, R - RIP,
        O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
        T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
        F - PBR, f - OpenFabric,
        > - selected route, * - FIB route, q - queued route, r - rejected route

I   203.0.113.0/24 [115/10] via 192.0.2.1, eth1, 00:03:42
```

**Enable IS-IS and IGP-LDP synchronization****Node 1:**

```
set interfaces loopback lo address 192.168.255.255/32
set interfaces ethernet eth0 address 192.0.2.1/24

set protocols isis interface eth0
set protocols isis interface lo passive
set protocols isis ldp-sync
set protocols isis net 49.0001.1921.6825.5255.00

set protocols mpls interface eth0
set protocols mpls ldp discovery transport-ipv4-address 192.168.255.255
set protocols mpls ldp interface lo
set protocols mpls ldp interface eth0
set protocols mpls ldp parameters transport-prefer-ipv4
set protocols mpls ldp router-id 192.168.255.255
```

This gives us IGP-LDP synchronization for all non-loopback interfaces with a holddown timer of zero seconds:

```
Node-1@vyos:~$ show isis mpls ldp-sync
eth0
  LDP-IGP Synchronization enabled: yes
  holddown timer in seconds: 0
  State: Sync achieved
```

## Enable IS-IS with Segment Routing (Experimental)

### Node 1:

```

set interfaces loopback lo address '192.168.255.255/32'
set interfaces ethernet eth1 address '192.0.2.1/24'

set protocols isis interface eth1
set protocols isis interface lo
set protocols isis net '49.0001.1921.6825.5255.00'
set protocols isis segment-routing global-block high-label-value '599'
set protocols isis segment-routing global-block low-label-value '550'
set protocols isis segment-routing prefix 192.168.255.255/32 index value '1'
set protocols isis segment-routing prefix 192.168.255.255/32 index explicit-null
set protocols mpls interface 'eth1'

```

### Node 2:

```

set interfaces loopback lo address '192.168.255.254/32'
set interfaces ethernet eth1 address '192.0.2.2/24'

set protocols isis interface eth1
set protocols isis interface lo
set protocols isis net '49.0001.1921.6825.5254.00'
set protocols isis segment-routing global-block high-label-value '599'
set protocols isis segment-routing global-block low-label-value '550'
set protocols isis segment-routing prefix 192.168.255.254/32 index value '2'
set protocols isis segment-routing prefix 192.168.255.254/32 index explicit-null
set protocols mpls interface 'eth1'

```

This gives us MPLS segment routing enabled and labels for far end loopbacks:

```

Node-1@vyos:~$ show mpls table
Inbound Label  Type      Nexthop      Outbound Label
-----
552            SR (IS-IS)  192.0.2.2    IPv4 Explicit Null <-- Node-2

I>* 192.168.255.254/32 [115/20] via 192.0.2.1, eth1, label IPv4 Explicit Null, weight 1, 00:03:43

```

## 8.9.7 MPLS

MPLS (Multi-Protocol Label Switching) is a packet forwarding paradigm which differs from regular IP forwarding. Instead of IP addresses being used to make the decision on finding the exit interface, a router will instead use an exact match on a 32 bit/4 byte header called the MPLS label. This label is inserted between the ethernet (layer 2) header and the IP (layer 3) header. One can statically or dynamically assign label allocations, but we will focus on dynamic allocation of labels using some sort of label distribution protocol (such as the aptly named Label Distribution Protocol / LDP, Resource Reservation Protocol / RSVP, or Segment Routing through OSPF/ISIS). These protocols allow for the creation of a unidirectional/unicast path called a labeled switched path (initialized as LSP) throughout the network that operates very much like a tunnel through the network. An easy way of thinking about how an MPLS LSP actually forwards traffic throughout a network is to think of a GRE tunnel. They are not the same in how they operate, but they are the same in how they handle the tunneled packet. It would be good to think of MPLS as a tunneling technology that can be used to transport many different types of packets, to aid in traffic engineering by allowing one to specify paths throughout the network (using RSVP or SR), and to generally allow for easier intra/inter network transport of data packets.

For more information on how MPLS label switching works, please go visit [Wikipedia \(MPLS\)](#).

---

**Bemerkung:** MPLS support in VyOS is not finished yet, and therefore its functionality is limited. Currently there is no support for MPLS enabled VPN services such as L2VPNs and mVPNs. RSVP support is also not present as the underlying routing stack (FRR) does not implement it. Currently VyOS implements LDP as described in RFC 5036; other LDP standard are the following ones: RFC 6720, RFC 6667, RFC 5919, RFC 5561, RFC 7552, RFC 4447. Because MPLS is already available (FRR also supports RFC 3031).

---

## Label Distribution Protocol

The MPLS architecture does not assume a single protocol to create MPLS paths. VyOS supports the Label Distribution Protocol (LDP) as implemented by FRR, based on [RFC 5036](#).

LDP (Label Distribution Protocol) is a TCP based MPLS signaling protocol that distributes labels creating MPLS label switched paths in a dynamic manner. LDP is not a routing protocol, as it relies on other routing protocols for forwarding decisions. LDP cannot bootstrap itself, and therefore relies on said routing protocols for communication with other routers that use LDP.

In order to allow for LDP on the local router to exchange label advertisements with other routers, a TCP session will be established between automatically discovered and statically assigned routers. LDP will try to establish a TCP session to the **transport address** of other routers. Therefore for LDP to function properly please make sure the transport address is shown in the routing table and reachable to traffic at all times.

It is highly recommended to use the same address for both the LDP router-id and the discovery transport address, but for VyOS MPLS LDP to work both parameters must be explicitly set in the configuration.

Another thing to keep in mind with LDP is that much like BGP, it is a protocol that runs on top of TCP. It however does not have an ability to do something like a refresh capability like BGP's route refresh capability. Therefore one might have to reset the neighbor for a capability change or a configuration change to work.

## Configuration Options

**set protocols mpls interface <interface>**

Use this command to enable MPLS processing on the interface you define.

**set protocols mpls ldp interface <interface>**

Use this command to enable LDP on the interface you define.

**set protocols mpls ldp router-id <address>**

Use this command to configure the IP address used as the LDP router-id of the local device.

**set protocols mpls ldp discovery transport-ipv4-address <address>**

**set protocols mpls ldp discovery transport-ipv6-address <address>**

Use this command to set the IPv4 or IPv6 transport-address used by LDP.

**set protocols mpls ldp neighbor <address> password <password>**

Use this command to configure authentication for LDP peers. Set the IP address of the LDP peer and a password that should be shared in order to become neighbors.

**set protocols mpls ldp neighbor <address> session-holdtime <seconds>**

Use this command to configure a specific session hold time for LDP peers. Set the IP address of the LDP peer and a session hold time that should be configured for it. You may have to reset the neighbor for this to work.

**set protocols mpls ldp neighbor <address> ttl-security <disable | hop count>**

Use this command to enable, disable, or specify hop count for TTL security for LDP peers. By default the value is set to 255 (or max TTL).

**set protocols mpls ldp discovery hello-ipv4-interval <seconds>**

**set protocols mpls ldp discovery hello-ipv4-holdtime <seconds>**

**set protocols mpls ldp discovery hello-ipv6-interval <seconds>**

**set protocols mpls ldp discovery hello-ipv6-holdtime <seconds>**

Use these commands if you would like to set the discovery hello and hold time parameters.

```
set protocols mpls ldp discovery session-ipv4-holdtime <seconds>
set protocols mpls ldp discovery session-ipv6-holdtime <seconds>
```

Use this command if you would like to set the TCP session hold time intervals.

```
set protocols mpls ldp import ipv4 import-filter filter-access-list <access list number>
set protocols mpls ldp import ipv6 import-filter filter-access-list6 <access list number>
```

Use these commands to control the importing of forwarding equivalence classes (FECs) for LDP from neighbors. This would be useful for example on only accepting the labeled routes that are needed and not ones that are not needed, such as accepting loopback interfaces and rejecting all others.

```
set protocols mpls ldp export ipv4 export-filter filter-access-list <access list number>
set protocols mpls ldp export ipv6 export-filter filter-access-list6 <access list number>
```

Use these commands to control the exporting of forwarding equivalence classes (FECs) for LDP to neighbors. This would be useful for example on only announcing the labeled routes that are needed and not ones that are not needed, such as announcing loopback interfaces and no others.

```
set protocols mpls ldp export ipv4 explicit-null
set protocols mpls ldp export ipv6 explicit-null
```

Use this command if you would like for the router to advertise FECs with a label of 0 for explicit null operations.

```
set protocols mpls ldp allocation ipv4 access-list <access list number>
set protocols mpls ldp allocation ipv6 access-list6 <access list number>
```

Use this command if you would like to control the local FEC allocations for LDP. A good example would be for your local router to not allocate a label for everything. Just a label for what it's useful. A good example would be just a loopback label.

```
set protocols mpls ldp parameters cisco-interop-tlv
```

Use this command to use a Cisco non-compliant format to send and interpret the Dual-Stack capability TLV for IPv6 LDP communications. This is related to [RFC 7552](#).

```
set protocols mpls ldp parameters ordered-control
```

Use this command to use ordered label distribution control mode. FRR by default uses independent label distribution control mode for label distribution. This is related to [RFC 5036](#).

```
set protocols mpls ldp parameters transport-prefer-ipv4
```

Use this command to prefer IPv4 for TCP peer transport connection for LDP when both an IPv4 and IPv6 LDP address are configured on the same interface.

```
set protocols mpls ldp targeted-neighbor ipv4 enable
set protocols mpls ldp targeted-neighbor ipv6 enable
```

Use this command to enable targeted LDP sessions to the local router. The router will then respond to any sessions that are trying to connect to it that are not a link local type of TCP connection.

```
set protocols mpls ldp targeted-neighbor ipv4 address <address>
set protocols mpls ldp targeted-neighbor ipv6 address <address>
```

Use this command to enable the local router to try and connect with a targeted LDP session to another router.

```
set protocols mpls ldp targeted-neighbor ipv4 hello-holdtime <seconds>
```

```
set protocols mpls ldp targeted-neighbor ipv4 hello-interval <seconds>
set protocols mpls ldp targeted-neighbor ipv6 hello-holdtime <seconds>
set protocols mpls ldp targeted-neighbor ipv6 hello-interval <seconds>
```

Use these commands if you would like to set the discovery hello and hold time parameters for the targeted LDP neighbors.

### Sample configuration to setup LDP on VyOS

```
set protocols ospf area 0 network '192.168.255.252/32' <--- Routing_
↳for loopback
set protocols ospf area 0 network '192.168.0.5/32' <--- Routing_
↳for an interface connecting to the network
set protocols ospf parameters router-id '192.168.255.252' <--- Router_
↳ID setting for OSPF
set protocols mpls interface 'eth1' <--- Enable_
↳MPLS for an interface connecting to network
set protocols mpls ldp discovery transport-ipv4-address '192.168.255.252' <---_
↳Transport address for LDP for TCP sessions to connect to
set protocols mpls ldp interface 'eth1' <--- Enable_
↳LDP for an interface connecting to network
set protocols mpls ldp interface 'lo' <--- Enable_
↳LDP on loopback for future services connectivity
set protocols mpls ldp router-id '192.168.255.252' <--- Router_
↳ID setting for LDP
set interfaces ethernet eth1 address '192.168.0.5/31' <---_
↳Interface IP for connecting to network
set interfaces loopback lo address '192.168.255.252/32' <---_
↳Interface loopback IP for router ID and other uses
```

### Operational Mode Commands

When LDP is working, you will be able to see label information in the outcome of `show ip route`. Besides that information, there are also specific `show` commands for LDP:

#### Show

##### `show mpls ldp binding`

Use this command to see the Label Information Base.

##### `show mpls ldp discovery`

Use this command to see discovery hello information

##### `show mpls ldp interface`

Use this command to see LDP interface information

##### `show mpls ldp neighbor`

Use this command to see LDP neighbor information

##### `show mpls ldp neighbor detail`

Use this command to see detailed LDP neighbor information

## Reset

**reset mpls ldp neighbor <IPv4 or IPv6 address>**

Use this command to reset an LDP neighbor/TCP session that is established

## 8.9.8 Segment Routing

Segment Routing (SR) is a network architecture that is similar to source-routing . In this architecture, the ingress router adds a list of segments, known as SIDs, to the packet as it enters the network. These segments represent different portions of the network path that the packet will take.

The SR segments are portions of the network path taken by the packet, and are called SIDs. At each node, the first SID of the list is read, executed as a forwarding function, and may be popped to let the next node read the next SID of the list. The SID list completely determines the path where the packet is forwarded.

Segment Routing can be applied to an existing MPLS-based data plane and defines a control plane network architecture. In MPLS networks, segments are encoded as MPLS labels and are added at the ingress router. These MPLS labels are then exchanged and populated by Interior Gateway Protocols (IGPs) like IS-IS or OSPF which are running on most ISPs.

---

**Bemerkung:** Segment routing defines a control plane network architecture and can be applied to an existing MPLS based dataplane. In the MPLS networks, segments are encoded as MPLS labels and are imposed at the ingress router. MPLS labels are exchanged and populated by IGPs like IS-IS. Segment Routing as per RFC8667 for MPLS dataplane. It supports IPv4, IPv6 and ECMP and has been tested against Cisco & Juniper routers. however, this deployment is still EXPERIMENTAL for FRR.

---

## IS-IS SR Configuration

Segment routing (SR) is used by the IGP protocols to interconnect network devices, below configuration shows how to enable SR on IS-IS:

---

**Bemerkung:** Known limitations:

No support for level redistribution (L1 to L2 or L2 to L1)

No support for binding SID

No support for SRLB

Only one SRGB and default SPF Algorithm is supported

---

**set protocols isis segment-routing global-block high-label-value <label-value>**

Set the Segment Routing Global Block i.e. the label range used by MPLS to store label in the MPLS FIB for Prefix SID. Note that the block size may not exceed 65535.

**set protocols isis segment-routing global-block low-label-value <label-value>**

Set the Segment Routing Global Block i.e. the low label range used by MPLS to store label in the MPLS FIB for Prefix SID. Note that the block size may not exceed 65535.

**set protocols isis segment-routing local-block high-label-value <label-value>**

Set the Segment Routing Local Block i.e. the label range used by MPLS to store label in the MPLS FIB for Prefix SID. Note that the block size may not exceed 65535. Segment Routing Local Block, The negative command always unsets both.

**set protocols isis segment-routing local-block <low-label-value <label-value>**

Set the Segment Routing Local Block i.e. the low label range used by MPLS to store label in the MPLS FIB for Prefix SID. Note that the block size may not exceed 65535. Segment Routing Local Block, The negative command always unsets both.

**set protocols isis segment-routing maximum-label-depth <1-16>**

Set the Maximum Stack Depth supported by the router. The value depend of the MPLS dataplane.

**set protocols isis segment-routing prefix <address> index value <0-65535>**

A segment ID that contains an IP address prefix calculated by an IGP in the service provider core network. Prefix SIDs are globally unique, this value identify it

**set protocols isis segment-routing prefix <address> index <no-php-flag | explicit-null | n-flag-clear>**

this option allows to configure prefix-sid on SR. The 'no-php-flag' means NO Penultimate Hop Popping that allows SR node to request to its neighbor to not pop the label. The 'explicit-null' flag allows SR node to request to its neighbor to send IP packet with the EXPLICIT-NULL label. The 'n-flag-clear' option can be used to explicitly clear the Node flag that is set by default for Prefix-SIDs associated to loopback addresses. This option is necessary to configure Anycast-SIDs.

**show isis segment-routing node**

Show detailed information about all learned Segment Routing Nodes

**show isis route prefix-sid**

Show detailed information about prefix-sid and label learned

---

**Bemerkung:** more information related IGP - [IS-IS](#)

---

## OSPF SR Configuration

Segment routing (SR) is used by the IGP protocols to interconnect network devices, below configuration shows how to enable SR on OSPF:

**set protocols ospf parameters opaque-lsa**

Enable the Opaque-LSA capability (rfc2370), necessary to transport label on IGP

**set protocols ospf segment-routing global-block high-label-value <label-value>**

Set the Segment Routing Global Block i.e. the label range used by MPLS to store label in the MPLS FIB for Prefix SID. Note that the block size may not exceed 65535.

**set protocols ospf segment-routing global-block low-label-value <label-value>**

Set the Segment Routing Global Block i.e. the low label range used by MPLS to store label in the MPLS FIB for Prefix SID. Note that the block size may not exceed 65535.

**set protocols ospf segment-routing local-block high-label-value <label-value>**

Set the Segment Routing Local Block i.e. the label range used by MPLS to store label in the MPLS FIB for Prefix SID. Note that the block size may not exceed 65535. Segment Routing Local Block, The negative command always unsets both.

**set protocols ospf segment-routing local-block <low-label-value <label-value>**

Set the Segment Routing Local Block i.e. the low label range used by MPLS to store label in the MPLS FIB for Prefix SID. Note that the block size may not exceed 65535. Segment Routing Local Block, The negative command always unsets both.

**set protocols ospf segment-routing maximum-label-depth <1-16>**

Set the Maximum Stack Depth supported by the router. The value depend of the MPLS dataplane.

**set protocols ospf segment-routing prefix <address> index value <0-65535>**

A segment ID that contains an IP address prefix calculated by an IGP in the service provider core network. Prefix SIDs are globally unique, this value identify it

**set protocols ospf segment-routing prefix <address> index <no-php-flag | explicit-null | n-flag-clear>**

this option allows to configure prefix-sid on SR. The 'no-php-flag' means NO Penultimate Hop Popping that allows SR node to request to its neighbor to not pop the label. The 'explicit-null' flag allows SR node to request to its neighbor to send IP packet with the EXPLICIT-NULL label. The 'n-flag-clear' option can be used to explicitly clear the Node flag that is set by default for Prefix-SIDs associated to loopback addresses. This option is necessary to configure Anycast-SIDs.

---

**Bemerkung:** more information related IGP - *OSPF*

---

## Configuration Example

we described the configuration SR ISIS / SR OSPF using 2 connected with them to share label information.

### Enable IS-IS with Segment Routing (Experimental)

#### Node 1:

```
set interfaces loopback lo address '192.168.255.255/32'
set interfaces ethernet eth1 address '192.0.2.1/24'

set protocols isis interface eth1
set protocols isis interface lo
set protocols isis net '49.0001.1921.6825.5255.00'
set protocols isis segment-routing global-block high-label-value '599'
set protocols isis segment-routing global-block low-label-value '550'
set protocols isis segment-routing prefix 192.168.255.255/32 index value '1'
set protocols isis segment-routing prefix 192.168.255.255/32 index explicit-null
set protocols mpls interface 'eth1'
```

#### Node 2:

```
set interfaces loopback lo address '192.168.255.254/32'
set interfaces ethernet eth1 address '192.0.2.2/24'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set protocols isis interface eth1
set protocols isis interface lo
set protocols isis net '49.0001.1921.6825.5254.00'
set protocols isis segment-routing global-block high-label-value '599'
set protocols isis segment-routing global-block low-label-value '550'
set protocols isis segment-routing prefix 192.168.255.254/32 index value '2'
set protocols isis segment-routing prefix 192.168.255.254/32 index explicit-null
set protocols mpls interface 'eth1'

```

This gives us MPLS segment routing enabled and labels for far end loopbacks:

```

Node-1@vyos:~$ show mpls table
Inbound Label  Type      Nexthop      Outbound Label
-----
552            SR (IS-IS)  192.0.2.2    IPv4 Explicit Null <-- Node-2
↳ loopback learned on Node-1
15000          SR (IS-IS)  192.0.2.2    implicit-null
15001          SR (IS-IS)  fe80::e87:6cff:fe09:1  implicit-null
15002          SR (IS-IS)  192.0.2.2    implicit-null
15003          SR (IS-IS)  fe80::e87:6cff:fe09:1  implicit-null

Node-2@vyos:~$ show mpls table
Inbound Label  Type      Nexthop      Outbound Label
-----
551            SR (IS-IS)  192.0.2.1    IPv4 Explicit Null <-- Node-1 loopback
↳ learned on Node-2
15000          SR (IS-IS)  192.0.2.1    implicit-null
15001          SR (IS-IS)  fe80::e33:2ff:fe80:1  implicit-null
15002          SR (IS-IS)  192.0.2.1    implicit-null
15003          SR (IS-IS)  fe80::e33:2ff:fe80:1  implicit-null

```

Here is the routing tables showing the MPLS segment routing label operations:

```

Node-1@vyos:~$ show ip route isis
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, F - PBR,
       f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup
       t - trapped, o - offload failure

I  192.0.2.0/24 [115/20] via 192.0.2.2, eth1 inactive, weight 1, 00:07:48
I>* 192.168.255.254/32 [115/20] via 192.0.2.2, eth1, label IPv4 Explicit Null, weight 1,
↳ 00:03:39

Node-2@vyos:~$ show ip route isis
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, F - PBR,
       f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

t - trapped, o - offload failure

```
I 192.0.2.0/24 [115/20] via 192.0.2.1, eth1 inactive, weight 1, 00:07:46
I>* 192.168.255.255/32 [115/20] via 192.0.2.1, eth1, label IPv4 Explicit Null, weight 1, 00:03:43
```

**Enable OSPF with Segment Routing (Experimental):****Node 1**

```
set interfaces loopback lo address 10.1.1.1/32
set interfaces ethernet eth0 address 192.168.0.1/24
set protocols ospf area 0 network '192.168.0.0/24'
set protocols ospf area 0 network '10.1.1.1/32'
set protocols ospf parameters opaque-lsa
set protocols ospf parameters router-id '10.1.1.1'
set protocols ospf segment-routing global-block high-label-value '1100'
set protocols ospf segment-routing global-block low-label-value '1000'
set protocols ospf segment-routing prefix 10.1.1.1/32 index explicit-null
set protocols ospf segment-routing prefix 10.1.1.1/32 index value '1'
```

**Node 2**

```
set interfaces loopback lo address 10.1.1.2/32
set interfaces ethernet eth0 address 192.168.0.2/24
set protocols ospf area 0 network '192.168.0.0/24'
set protocols ospf area 0 network '10.1.1.2/32'
set protocols ospf parameters opaque-lsa
set protocols ospf parameters router-id '10.1.1.2'
set protocols ospf segment-routing global-block high-label-value '1100'
set protocols ospf segment-routing global-block low-label-value '1000'
set protocols ospf segment-routing prefix 10.1.1.2/32 index explicit-null
set protocols ospf segment-routing prefix 10.1.1.2/32 index value '2'
```

This gives us MPLS segment routing enabled and labels for far end loopbacks:

```
Node-1@vyos:~$ show mpls table
Inbound Label  Type      Nexthop      Outbound Label
-----
1002          SR (OSPF)  192.168.0.2  IPv4 Explicit Null  <-- Node-2 loopback learned
on Node-1
15000         SR (OSPF)  192.168.0.2  implicit-null
15001         SR (OSPF)  192.168.0.2  implicit-null

Node-2@vyos:~$ show mpls table
Inbound Label  Type      Nexthop      Outbound Label
-----
1001          SR (OSPF)  192.168.0.1  IPv4 Explicit Null  <-- Node-1 loopback learned
on Node-2
15000         SR (OSPF)  192.168.0.1  implicit-null
15001         SR (OSPF)  192.168.0.1  implicit-null
```

Here is the routing tables showing the MPLS segment routing label operations:

```
Node-1@vyos:~$ show ip route ospf

### 8.9.9 OSPF

OSPF (Open Shortest Path First) is a routing protocol for Internet Protocol (IP) networks. It uses a link state routing (LSR) algorithm and falls into the group of interior gateway protocols (IGPs), operating within a single autonomous system (AS). It is defined as OSPF Version 2 in [RFC 2328](#) (1998) for IPv4. Updates for IPv6 are specified as OSPF Version 3 in [RFC 5340](#) (2008). OSPF supports the CIDR (Classless Inter-Domain Routing) addressing model.

OSPF is a widely used IGP in large enterprise networks.

#### OSPFv2 (IPv4)

##### Configuration

##### General

VyOS does not have a special command to start the OSPF process. The OSPF process starts when the first ospf enabled interface is configured.

**set protocols ospf area <number> network <A.B.C.D/M>**

This command specifies the OSPF enabled interface(s). If the interface has an address from defined range then the command enables OSPF on this interface so router can provide network information to the other ospf routers via this interface.

This command is also used to enable the OSPF process. The area number can be specified in decimal notation in the range from 0 to 4294967295. Or it can be specified in dotted decimal notation similar to ip address.

Prefix length in interface must be equal or bigger (i.e. smaller network) than prefix length in network statement. For example statement above doesn't enable ospf on interface with address 192.168.1.1/23, but it does on interface with address 192.168.1.129/25.

In some cases it may be more convenient to enable OSPF on a per interface/subnet basis `set protocols ospf interface <interface> area <x.x.x.x | x>`

#### **set protocols ospf auto-cost reference-bandwidth <number>**

This command sets the reference bandwidth for cost calculations, where bandwidth can be in range from 1 to 4294967, specified in Mbits/s. The default is 100Mbit/s (i.e. a link of bandwidth 100Mbit/s or higher will have a cost of 1. Cost of lower bandwidth links will be scaled with reference to this cost).

#### **set protocols ospf parameters router-id <rid>**

This command sets the router-ID of the OSPF process. The router-ID may be an IP address of the router, but need not be – it can be any arbitrary 32bit number. However it **MUST** be unique within the entire OSPF domain to the OSPF speaker – bad things will happen if multiple OSPF speakers are configured with the same router-ID!

### Optional

#### **set protocols ospf default-information originate [always] [metric <number>] [metric-type <1|2>] [route-map <name>]**

Originate an AS-External (type-5) LSA describing a default route into all external-routing capable areas, of the specified metric and metric type. If the `always` keyword is given then the default is always advertised, even when there is no default present in the routing table. The argument `route-map` specifies to advertise the default route if the route map is satisfied.

#### **set protocols ospf distance global <distance>**

This command change distance value of OSPF globally. The distance range is 1 to 255.

#### **set protocols ospf distance ospf <external|inter-area|intra-area> <distance>**

This command change distance value of OSPF. The arguments are the distance values for external routes, inter-area routes and intra-area routes respectively. The distance range is 1 to 255.

---

**Bemerkung:** Routes with a distance of 255 are effectively disabled and not installed into the kernel.

---

#### **set protocols ospf log-adjacency-changes [detail]**

This command allows to log changes in adjacency. With the optional `detail` argument, all changes in adjacency status are shown. Without `detail`, only changes to full or regressions are shown.

#### **set protocols ospf max-metric router-lsa <administrative|on-shutdown <seconds>|on-startup <seconds>>**

This enables [RFC 3137](#) support, where the OSPF process describes its transit links in its router-LSA as having infinite distance so that other routers will avoid calculating transit paths through the router while still being able to reach networks through the router.

This support may be enabled administratively (and indefinitely) with the `administrative` command. It may also be enabled conditionally. Conditional enabling of max-metric router-lsas can be for a period of seconds after startup with the `on-startup <seconds>` command and/or for a period of seconds prior to shutdown with the `on-shutdown <seconds>` command. The time range is 5 to 86400.

#### **set protocols ospf parameters abr-type <cisco|ibm|shortcut|standard>**

This command selects ABR model. OSPF router supports four ABR models:

**cisco** – a router will be considered as ABR if it has several configured links to the networks in different areas one of which is a backbone area. Moreover, the link to the backbone area should be active (working). **ibm** – identical to „cisco“ model but in this case a backbone area link may not be active. **standard** – router has several active links to different areas. **shortcut** – identical to „standard“ but in this model a router is allowed to use a connected areas topology without involving a backbone area for inter-area connections.

Detailed information about „cisco“ and „ibm“ models differences can be found in [RFC 3509](#). A „shortcut“ model allows ABR to create routes between areas based on the topology of the areas connected to this router but not using a backbone area in case if non-backbone route will be cheaper. For more information about „shortcut“ model, see *ospf-shortcut-abr-02.txt*

#### **set protocols ospf parameters rfc1583-compatibility**

[RFC 2328](#), the successor to [RFC 1583](#), suggests according to section G.2 (changes) in section 16.4.1 a change to the path preference algorithm that prevents possible routing loops that were possible in the old version of OSPFv2. More specifically it demands that inter-area paths and intra-area backbone path are now of equal preference but still both preferred to external paths.

This command should NOT be set normally.

#### **set protocols ospf interface <interface> passive [disable]**

This command specifies interface as passive. Passive interface advertises its address, but does not run the OSPF protocol (adjacencies are not formed and hello packets are not generated).

The optional *disable* option allows to exclude interface from passive state. This command is used if the command `passive-interface default` was configured.

#### **set protocols ospf passive-interface default**

This command specifies all interfaces as passive by default. Because this command changes the configuration logic to a default passive; therefore, interfaces where router adjacencies are expected need to be configured with the `passive-interface-exclude` command.

#### **set protocols ospf maximum-paths <1-64>**

Use this command to control the maximum number of equal cost paths to reach a specific destination. The upper limit may differ if you change the value of MULTIPATH\_NUM during compilation. The default is MULTIPATH\_NUM (64).

#### **set protocols ospf refresh timers <seconds>**

The router automatically updates link-state information with its neighbors. Only an obsolete information is updated which age has exceeded a specific threshold. This parameter changes a threshold value, which by default is 1800 seconds (half an hour). The value is applied to the whole OSPF router. The timer range is 10 to 1800.

#### **set protocols ospf timers throttle spf <delay|initial-holdtime|max-holdtime> <seconds>**

This command sets the initial delay, the initial-holdtime and the maximum-holdtime between when SPF is calculated and the event which triggered the calculation. The times are specified in milliseconds and must be in the range of 0 to 600000 milliseconds. *delay* sets the initial SPF schedule delay in milliseconds. The default value is 200 ms. *initial-holdtime* sets the minimum hold time between two consecutive SPF calculations. The default value is 1000 ms. *max-holdtime* sets the maximum wait time between two consecutive SPF calculations. The default value is 10000 ms.

#### **set protocols ospf ldp-sync**

This command will enable IGP-LDP synchronization globally for OSPF. This requires for LDP to be functional. This is described in [RFC 5443](#). By default all interfaces operational in OSPF are enabled for synchronization. Loopbacks are exempt.

**set protocols ospf ldp-sync holddown <seconds>**

This command will change the hold down value globally for IGP-LDP synchronization during convergence/interface flap events.

**set protocols ospf capability opaque**

ospfd supports Opaque LSA [RFC 2370](#) as partial support for MPLS Traffic Engineering LSAs. The opaque-lsa capability must be enabled in the configuration.

An alternate command could be „mpls-te on“ (Traffic Engineering)

---

**Bemerkung:** FRR offers only partial support for some of the routing protocol extensions that are used with MPLS-TE; it does not support a complete RSVP-TE solution.

---

## Area Configuration

**set protocols ospf area <number> area-type stub**

This command specifies the area to be a Stub Area. That is, an area where no router originates routes external to OSPF and hence an area where all external routes are via the ABR(s). Hence, ABRs for such an area do not need to pass AS-External LSAs (type-5) or ASBR-Summary LSAs (type-4) into the area. They need only pass Network-Summary (type-3) LSAs into such an area, along with a default-route summary.

**set protocols ospf area <number> area-type stub no-summary**

This command specifies the area to be a Totally Stub Area. In addition to stub area limitations this area type prevents an ABR from injecting Network-Summary (type-3) LSAs into the specified stub area. Only default summary route is allowed.

**set protocols ospf area <number> area-type stub default-cost <number>**

This command sets the cost of default-summary LSAs announced to stubby areas. The cost range is 0 to 16777215.

**set protocols ospf area <number> area-type nssa**

This command specifies the area to be a Not So Stubby Area. External routing information is imported into an NSSA in Type-7 LSAs. Type-7 LSAs are similar to Type-5 AS-external LSAs, except that they can only be flooded into the NSSA. In order to further propagate the NSSA external information, the Type-7 LSA must be translated to a Type-5 AS-external-LSA by the NSSA ABR.

**set protocols ospf area <number> area-type nssa no-summary**

This command specifies the area to be a NSSA Totally Stub Area. ABRs for such an area do not need to pass Network-Summary (type-3) LSAs (except the default summary route), ASBR-Summary LSAs (type-4) and AS-External LSAs (type-5) into the area. But Type-7 LSAs that convert to Type-5 at the NSSA ABR are allowed.

**set protocols ospf area <number> area-type nssa default-cost <number>**

This command sets the default cost of LSAs announced to NSSA areas. The cost range is 0 to 16777215.

**set protocols ospf area <number> area-type nssa translate <always|candidate|never>**

Specifies whether this NSSA border router will unconditionally translate Type-7 LSAs into Type-5 LSAs. When role is Always, Type-7 LSAs are translated into Type-5 LSAs regardless of the translator state of other NSSA border routers. When role is Candidate, this router participates in the translator election to determine if it will perform the translations duties. When role is Never, this router will never translate Type-7 LSAs into Type-5 LSAs.

**set protocols ospf area <number> authentication plaintext-password**

This command specifies that simple password authentication should be used for the given area. The password must also be configured on a per-interface basis.

**set protocols ospf area <number> authentication md5**

This command specifies that OSPF packets must be authenticated with MD5 HMACs within the given area. Keying material must also be configured on a per-interface basis.

**set protocols ospf area <number> range <A.B.C.D/M> [cost <number>]**

This command summarizes intra area paths from specified area into one summary-LSA (Type-3) announced to other areas. This command can be used only in ABR and ONLY router-LSAs (Type-1) and network-LSAs (Type-2) (i.e. LSAs with scope area) can be summarized. AS-external-LSAs (Type-5) can't be summarized - their scope is AS. The optional argument cost specifies the aggregated link metric. The metric range is 0 to 16777215.

**set protocols ospf area <number> range <A.B.C.D/M> not-advertise**

This command instead of summarizing intra area paths filter them - i.e. intra area paths from this range are not advertised into other areas. This command makes sense in ABR only.

**set protocols ospf area <number> export-list <acl\_number>**

Filter Type-3 summary-LSAs announced to other areas originated from intra- area paths from specified area. This command makes sense in ABR only.

**set protocols ospf area <number> import-list <acl\_number>**

Same as export-list, but it applies to paths announced into specified area as Type-3 summary-LSAs. This command makes sense in ABR only.

**set protocols ospf area <number> range <A.B.C.D/M> substitute <E.F.G.H/M>**

One Type-3 summary-LSA with routing info <E.F.G.H/M> is announced into backbone area if defined area contains at least one intra-area network (i.e. described with router-LSA or network-LSA) from range <A.B.C.D/M>. This command makes sense in ABR only.

**set protocols ospf area <number> shortcut <default|disable|enable>**

This parameter allows to „shortcut“ routes (non-backbone) for inter-area routes. There are three modes available for routes shortcutting:

**default** – this area will be used for shortcutting only if ABR does not have a link to the backbone area or this link was lost. **enable** – the area will be used for shortcutting every time the route that goes through it is cheaper.

**disable** – this area is never used by ABR for routes shortcutting.

**set protocols ospf area <number> virtual-link <A.B.C.D>**

Provides a backbone area coherence by virtual link establishment.

In general, OSPF protocol requires a backbone area (area 0) to be coherent and fully connected. I.e. any backbone area router must have a route to any other backbone area router. Moreover, every ABR must have a link to backbone area. However, it is not always possible to have a physical link to a backbone area. In this case between two ABR (one of them has a link to the backbone area) in the area (not stub area) a virtual link is organized.

<number> – area identifier through which a virtual link goes. <A.B.C.D> – ABR router-id with which a virtual link is established. Virtual link must be configured on both routers.

Formally, a virtual link looks like a point-to-point network connecting two ABR from one area one of which physically connected to a backbone area. This pseudo-network is considered to belong to a backbone area.

## Interface Configuration

**set protocols ospf interface <interface> area <x.x.x.x | x>**

Enable ospf on an interface and set associated area.

If you have a lot of interfaces, and/or a lot of subnets, then enabling OSPF via this command may result in a slight performance improvement.

**set protocols ospf interface <interface> authentication plaintext-password <text>**

This command sets OSPF authentication key to a simple password. After setting, all OSPF packets are authenticated. Key has length up to 8 chars.

Simple text password authentication is insecure and deprecated in favour of MD5 HMAC authentication.

**set protocols ospf interface <interface> authentication md5 key-id <id> md5-key <text>**

This command specifies that MD5 HMAC authentication must be used on this interface. It sets OSPF authentication key to a cryptographic password. Key-id identifies secret key used to create the message digest. This ID is part of the protocol and must be consistent across routers on a link. The key can be long up to 16 chars (larger strings will be truncated), and is associated with the given key-id.

**set protocols ospf interface <interface> bandwidth <number>**

This command sets the interface bandwidth for cost calculations, where bandwidth can be in range from 1 to 100000, specified in Mbits/s.

**set protocols ospf interface <interface> cost <number>**

This command sets link cost for the specified interface. The cost value is set to router-LSA's metric field and used for SPF calculation. The cost range is 1 to 65535.

**set protocols ospf interface <interface> dead-interval <number>**

Set number of seconds for router Dead Interval timer value used for Wait Timer and Inactivity Timer. This value must be the same for all routers attached to a common network. The default value is 40 seconds. The interval range is 1 to 65535.

**set protocols ospf interface <interface> hello-multiplier <number>**

The hello-multiplier specifies how many Hellos to send per second, from 1 (every second) to 10 (every 100ms). Thus one can have 1s convergence time for OSPF. If this form is specified, then the hello-interval advertised in Hello packets is set to 0 and the hello-interval on received Hello packets is not checked, thus the hello-multiplier need NOT be the same across multiple routers on a common link.

**set protocols ospf interface <interface> hello-interval <number>**

Set number of seconds for Hello Interval timer value. Setting this value, Hello packet will be sent every timer value seconds on the specified interface. This value must be the same for all routers attached to a common network. The default value is 10 seconds. The interval range is 1 to 65535.

**set protocols ospf interface <interface> bfd**

This command enables BFD on this OSPF link interface.

**set protocols ospf interface <interface> mtu-ignore**

This command disables check of the MTU value in the OSPF DBD packets. Thus, use of this command allows the OSPF adjacency to reach the FULL state even though there is an interface MTU mismatch between two OSPF routers.

**set protocols ospf interface <interface> network <type>**

This command allows to specify the distribution type for the network connected to this interface:

**broadcast** – broadcast IP addresses distribution. **non-broadcast** – address distribution in NBMA networks topology. **point-to-multipoint** – address distribution in point-to-multipoint networks. **point-to-point** – address distribution in point-to-point networks.

**set protocols ospf interface <interface> priority <number>**

This command sets Router Priority integer value. The router with the highest priority will be more eligible to become Designated Router. Setting the value to 0, makes the router ineligible to become Designated Router. The default value is 1. The interval range is 0 to 255.

**set protocols ospf interface <interface> retransmit-interval <number>**

This command sets number of seconds for RxmtInterval timer value. This value is used when retransmitting Database Description and Link State Request packets if acknowledge was not received. The default value is 5 seconds. The interval range is 3 to 65535.

**set protocols ospf interface <interface> transmit-delay <number>**

This command sets number of seconds for InfTransDelay value. It allows to set and adjust for each interface the delay interval before starting the synchronizing process of the router's database with all neighbors. The default value is 1 seconds. The interval range is 3 to 65535.

**set protocols ospf interface <interface> ldp-sync disable**

This command disables IGP-LDP sync for this specific interface.

**set protocols ospf interface <interface> ldp-sync holddown <seconds>**

This command will change the hold down value for IGP-LDP synchronization during convergence/interface flap events, but for this interface only.

## External Route Summarisation

This feature summarises originated external LSAs (Type-5 and Type-7). Summary Route will be originated on-behalf of all matched external LSAs.

**set protocols ospf aggregation timer <seconds>**

Configure aggregation delay timer interval.

Summarisation starts only after this delay timer expiry.

**set protocols ospf summary-address x.x.x.x/y [tag (1-4294967295)]**

This command enable/disables summarisation for the configured address range.

Tag is the optional parameter. If tag configured Summary route will be originated with the configured tag.

**set protocols ospf summary-address x.x.x.x/y no-advertise**

This command to ensure not advertise the summary lsa for the matched external LSAs.

## Graceful Restart

**set protocols ospf graceful-restart [grace-period (1-1800)]**

Configure Graceful Restart [RFC 3623](#) restarting support. When enabled, the default grace period is 120 seconds.

To perform a graceful shutdown, the FRR graceful-restart prepare ip ospf EXEC-level command needs to be issued before restarting the ospfd daemon.

**set protocols ospf graceful-restart helper enable [router-id A.B.C.D]**

Configure Graceful Restart [RFC 3623](#) helper support. By default, helper support is disabled for all neighbours. This config enables/disables helper support on this router for all neighbours.

To enable/disable helper support for a specific neighbour, the router-id (A.B.C.D) has to be specified.

**set protocols ospf graceful-restart helper no-strict-lsa-checking**

By default *strict-lsa-checking* is configured then the helper will abort the Graceful Restart when a LSA change occurs which affects the restarting router.

This command disables it.

**set protocols ospf graceful-restart helper supported-grace-time**

Supports as HELPER for configured grace period.

**set protocols ospf graceful-restart helper planned-only**

It helps to support as HELPER only for planned restarts.

By default, it supports both planned and unplanned outages.

## Manual Neighbor Configuration

OSPF routing devices normally discover their neighbors dynamically by listening to the broadcast or multicast hello packets on the network. Because an NBMA network does not support broadcast (or multicast), the device cannot discover its neighbors dynamically, so you must configure all the neighbors statically.

**set protocols ospf neighbor <A.B.C.D>**

This command specifies the IP address of the neighboring device.

**set protocols ospf neighbor <A.B.C.D> poll-interval <seconds>**

This command specifies the length of time, in seconds, before the routing device sends hello packets out of the interface before it establishes adjacency with a neighbor. The range is 1 to 65535 seconds. The default value is 60 seconds.

**set protocols ospf neighbor <A.B.C.D> priority <number>**

This command specifies the router priority value of the nonbroadcast neighbor associated with the IP address specified. The default is 0. This keyword does not apply to point-to-multipoint interfaces.

## Redistribution Configuration

### **set protocols ospf redistribute <route source>**

This command redistributes routing information from the given route source to the OSPF process. There are five modes available for route source: bgp, connected, kernel, rip, static.

### **set protocols ospf default-metric <number>**

This command specifies the default metric value of redistributed routes. The metric range is 0 to 16777214.

### **set protocols ospf redistribute <route source> metric <number>**

This command specifies metric for redistributed routes from the given route source. There are five modes available for route source: bgp, connected, kernel, rip, static. The metric range is 1 to 16777214.

### **set protocols ospf redistribute <route source> metric-type <1|2>**

This command specifies metric type for redistributed routes. Difference between two metric types that metric type 1 is a metric which is „commensurable“ with inner OSPF links. When calculating a metric to the external destination, the full path metric is calculated as a metric sum path of a router which had advertised this link plus the link metric. Thus, a route with the least summary metric will be selected. If external link is advertised with metric type 2 the path is selected which lies through the router which advertised this link with the least metric despite of the fact that internal path to this router is longer (with more cost). However, if two routers advertised an external link and with metric type 2 the preference is given to the path which lies through the router with a shorter internal path. If two different routers advertised two links to the same external destination but with different metric type, metric type 1 is preferred. If type of a metric left undefined the router will consider these external links to have a default metric type 2.

### **set protocols ospf redistribute <route source> route-map <name>**

This command allows to use route map to filter redistributed routes from the given route source. There are five modes available for route source: bgp, connected, kernel, rip, static.

## Operational Mode Commands

### **show ip ospf neighbor**

This command displays the neighbors status.

Neighbor ID	Pri	State	Dead Time	Address	Interface
↪ RXmtL RqstL DBsmL					
10.0.13.1	1	Full/DR	38.365s	10.0.13.1	eth0:10.0.13.3
↪ 0	0	0			
10.0.23.2	1	Full/Backup	39.175s	10.0.23.2	eth1:10.0.23.3
↪ 0	0	0			

### **show ip ospf neighbor detail**

This command displays the neighbors information in a detailed form, not just a summary table.

```
Neighbor 10.0.13.1, interface address 10.0.13.1
In the area 0.0.0.0 via interface eth0
Neighbor priority is 1, State is Full, 5 state changes
Most recent state change statistics:
  Progressive change 11m55s ago
DR is 10.0.13.1, BDR is 10.0.13.3

```

#### **show ip ospf neighbor <A.B.C.D>**

This command displays the neighbors information in a detailed form for a neighbor whose IP address is specified.

#### **show ip ospf neighbor <interface>**

This command displays the neighbors status for a neighbor on the specified interface.

#### **show ip ospf interface [<interface>]**

This command displays state and configuration of OSPF the specified interface, or all interfaces if no interface is given.

```
eth0 is up

```

**show ip ospf route [detail]**

This command displays the OSPF routing table, as determined by the most recent SPF calculation. With the optional detail argument, each route item's advertiser router and network attribute will be shown.

```
===== OSPF network routing table =====
N IA 10.0.12.0/24      [3] area: 0.0.0.0
                        via 10.0.13.3, eth0
N   10.0.13.0/24      [1] area: 0.0.0.0
                        directly attached to eth0
N IA 10.0.23.0/24      [2] area: 0.0.0.0
                        via 10.0.13.3, eth0
N   10.0.34.0/24      [2] area: 0.0.0.0
                        via 10.0.13.3, eth0

===== OSPF router routing table =====
R   10.0.23.3          [1] area: 0.0.0.0, ABR
                        via 10.0.13.3, eth0
R   10.0.34.4          [2] area: 0.0.0.0, ASBR
                        via 10.0.13.3, eth0

===== OSPF external routing table =====
N E2 172.16.0.0/24     [2/20] tag: 0
                        via 10.0.13.3, eth0
```

The table consists of following data:

**OSPF network routing table** – includes a list of acquired routes for all accessible networks (or aggregated area ranges) of OSPF system. „IA“ flag means that route destination is in the area to which the router is not connected, i.e. it's an inter-area path. In square brackets a summary metric for all links through which a path lies to this network is specified. „via“ prefix defines a router-gateway, i.e. the first router on the way to the destination (next hop). **OSPF router routing table** – includes a list of acquired routes to all accessible ABRs and ASBRs. **OSPF external routing table** – includes a list of acquired routes that are external to the OSPF process. „E“ flag points to the external link metric type (E1 – metric type 1, E2 – metric type 2). External link metric is printed in the „<metric of the router which advertised the link>/<link metric>“ format.

**show ip ospf border-routers**

This command displays a table of paths to area boundary and autonomous system boundary routers.

**show ip ospf database**

This command displays a summary table with a database contents (LSA).

```

**show ip ospf database <type> [A.B.C.D] [adv-router <A.B.C.D>|self-originate]**

This command displays a database contents for a specific link advertisement type.

The type can be the following: asbr-summary, external, network, nssa-external, opaque-area, opaque-as, opaque-link, router, summary.

[A.B.C.D] – link-state-id. With this specified the command displays portion of the network environment that is being described by the advertisement. The value entered depends on the advertisement's LS type. It must be entered in the form of an IP address.

adv-router <A.B.C.D> – router id, which link advertisements need to be reviewed.

self-originate displays only self-originated LSAs from the local router.

## OSPF Router with ID (10.0.13.1)

## Router Link States (Area 0.0.0.0)

```

TOS 0 Metric: 1
```

### show ip ospf database max-age

This command displays LSAs in MaxAge list.

## Examples

### Enable OSPF

#### Node 1

```
set interfaces loopback lo address 10.1.1.1/32
set interfaces ethernet eth0 address 192.168.0.1/24
set protocols ospf area 0 network 192.168.0.0/24
set protocols ospf area 0 network 10.1.1.1/32
set protocols ospf parameters router-id 10.1.1.1
```

#### Node 2

```
set interfaces loopback lo address 10.1.1.2/32
set interfaces ethernet eth0 address 192.168.0.2/24
set protocols ospf area 0 network 192.168.0.0/24
set protocols ospf area 0 network 10.1.1.2/32
set protocols ospf parameters router-id 10.1.1.2
```

Here's the neighbors up:

```
Node-1@vyos:~$ show ip ospf neighbor
```

Neighbor ID	Pri	State	Up Time	Dead Time	Address	Interface
10.1.1.2	1	Full/DR	3m43s	36.094s	192.168.0.2	eth0:192.
168.0.1			0	0		

```
Node-2@vyos:~$ show ip ospf neighbor
```

Neighbor ID	Pri	State	Up Time	Dead Time	Address	Interface
10.1.1.1	1	Full/Backup	3m47s	31.736s	192.168.0.1	eth0:192.
168.0.2			0	0		

Here's the routes:

```
Node-1@vyos:~$ show ip route ospf
Codes: K - kernel route, C - connected, S - static, R - RIP,
O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

T - Table, v - VNC, V - VNC-Direct, A - Babel, F - PBR,
f - OpenFabric,
> - selected route, * - FIB route, q - queued, r - rejected, b - backup
t - trapped, o - offload failure

O 10.1.1.1/32 [110/0] is directly connected, lo, weight 1, 00:00:14
O>* 10.1.1.2/32 [110/1] via 192.168.0.2, eth0, weight 1, 00:00:07
O 192.168.0.0/24 [110/1] is directly connected, eth0, weight 1, 00:03:32

Node-2@vyos:~$ show ip route ospf
Codes: K - kernel route, C - connected, S - static, R - RIP,
O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
T - Table, v - VNC, V - VNC-Direct, A - Babel, F - PBR,
f - OpenFabric,
> - selected route, * - FIB route, q - queued, r - rejected, b - backup
t - trapped, o - offload failure

O>* 10.1.1.1/32 [110/1] via 192.168.0.1, eth0, weight 1, 00:00:11
O 10.1.1.2/32 [110/0] is directly connected, lo, weight 1, 00:00:04
O 192.168.0.0/24 [110/1] is directly connected, eth0, weight 1, 00:03:18

```

### Enable OSPF with route redistribution of the loopback and default originate:

#### Node 1

```

set interfaces loopback lo address 10.1.1.1/32
set protocols ospf area 0 network 192.168.0.0/24
set protocols ospf default-information originate always
set protocols ospf default-information originate metric 10
set protocols ospf default-information originate metric-type 2
set protocols ospf log-adjacency-changes
set protocols ospf parameters router-id 10.1.1.1
set protocols ospf redistribute connected metric-type 2
set protocols ospf redistribute connected route-map CONNECT

set policy route-map CONNECT rule 10 action permit
set policy route-map CONNECT rule 10 match interface lo

```

#### Node 2

```

set interfaces loopback lo address 10.2.2.2/32
set protocols ospf area 0 network 192.168.0.0/24
set protocols ospf log-adjacency-changes
set protocols ospf parameters router-id 10.2.2.2
set protocols ospf redistribute connected metric-type 2
set protocols ospf redistribute connected route-map CONNECT

set policy route-map CONNECT rule 10 action permit
set policy route-map CONNECT rule 10 match interface lo

```

**Enable OSPF and IGP-LDP synchronization:****Node 1:**

```

set interfaces loopback lo address 10.1.1.1/32
set interfaces ethernet eth0 address 192.168.0.1/24

set protocols ospf area 0 network '192.168.0.0/24'
set protocols ospf area 0 network '10.1.1.1/32'
set protocols ospf parameters router-id '10.1.1.1'
set protocols ospf ldp-sync

set protocols mpls interface eth0
set protocols mpls ldp discovery transport-ipv4-address 10.1.1.1
set protocols mpls ldp interface lo
set protocols mpls ldp interface eth0
set protocols mpls ldp parameters transport-prefer-ipv4
set protocols mpls ldp router-id 10.1.1.1

```

This gives us IGP-LDP synchronization for all non-loopback interfaces with a holddown timer of zero seconds:

```

Node-1@vyos:~$ show ip ospf mpls ldp-sync
eth0
LDP-IGP Synchronization enabled: yes
Holddown timer in seconds: 0
State: Sync achieved

```

**Enable OSPF with Segment Routing (Experimental):****Node 1**

```

set interfaces loopback lo address 10.1.1.1/32
set interfaces ethernet eth0 address 192.168.0.1/24

set protocols ospf area 0 network '192.168.0.0/24'
set protocols ospf area 0 network '10.1.1.1/32'
set protocols ospf parameters opaque-lsa
set protocols ospf parameters router-id '10.1.1.1'
set protocols ospf segment-routing global-block high-label-value '1100'
set protocols ospf segment-routing global-block low-label-value '1000'
set protocols ospf segment-routing prefix 10.1.1.1/32 index explicit-null
set protocols ospf segment-routing prefix 10.1.1.1/32 index value '1'

```

**Node 2**

```

set interfaces loopback lo address 10.1.1.2/32
set interfaces ethernet eth0 address 192.168.0.2/24

set protocols ospf area 0 network '192.168.0.0/24'
set protocols ospf area 0 network '10.1.1.2/32'
set protocols ospf parameters opaque-lsa
set protocols ospf parameters router-id '10.1.1.2'

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set protocols ospf segment-routing global-block high-label-value '1100'
set protocols ospf segment-routing global-block low-label-value '1000'
set protocols ospf segment-routing prefix 10.1.1.2/32 index explicit-null
set protocols ospf segment-routing prefix 10.1.1.2/32 index value '2'
```

This gives us MPLS segment routing enabled and labels for far end loopbacks:

```
Node-1@vyos:~$ show mpls table
Inbound Label  Type      Nexthop      Outbound Label
-----
1002           SR (OSPF)    192.168.0.2  IPv4 Explicit Null  <-- Node-2 loopback learned
on Node-1
15000          SR (OSPF)    192.168.0.2  implicit-null
15001          SR (OSPF)    192.168.0.2  implicit-null

Node-2@vyos:~$ show mpls table
Inbound Label  Type      Nexthop      Outbound Label
-----
1001           SR (OSPF)    192.168.0.1  IPv4 Explicit Null  <-- Node-1 loopback learned
on Node-2
15000          SR (OSPF)    192.168.0.1  implicit-null
15001          SR (OSPF)    192.168.0.1  implicit-null
```

Here is the routing tables showing the MPLS segment routing label operations:

```
Node-1@vyos:~$ show ip route ospf
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, F - PBR,
       f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup
       t - trapped, o - offload failure

O   10.1.1.1/32 [110/0] is directly connected, lo, weight 1, 00:03:43
O>* 10.1.1.2/32 [110/1] via 192.168.0.2, eth0, label IPv4 Explicit Null, weight 1,
on 00:03:32
O   192.168.0.0/24 [110/1] is directly connected, eth0, weight 1, 00:03:43

Node-2@vyos:~$ show ip route ospf
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, F - PBR,
       f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup
       t - trapped, o - offload failure

O>* 10.1.1.1/32 [110/1] via 192.168.0.1, eth0, label IPv4 Explicit Null, weight 1,
on 00:03:36
O   10.1.1.2/32 [110/0] is directly connected, lo, weight 1, 00:03:51
O   192.168.0.0/24 [110/1] is directly connected, eth0, weight 1, 00:03:51
```

## OSPFv3 (IPv6)

### Configuration

#### General

VyOS does not have a special command to start the OSPFv3 process. The OSPFv3 process starts when the first ospf enabled interface is configured.

**set protocols ospfv3 interface <interface> area <number>**

This command specifies the OSPFv3 enabled interface. This command is also used to enable the OSPF process. The area number can be specified in decimal notation in the range from 0 to 4294967295. Or it can be specified in dotted decimal notation similar to ip address.

**set protocols ospfv3 parameters router-id <rid>**

This command sets the router-ID of the OSPFv3 process. The router-ID may be an IP address of the router, but need not be – it can be any arbitrary 32bit number. However it MUST be unique within the entire OSPFv3 domain to the OSPFv3 speaker – bad things will happen if multiple OSPFv3 speakers are configured with the same router-ID!

#### Optional

**set protocols ospfv3 distance global <distance>**

This command change distance value of OSPFv3 globally. The distance range is 1 to 255.

**set protocols ospfv3 distance ospfv3 <external|inter-area|intra-area> <distance>**

This command change distance value of OSPFv3. The arguments are the distance values for external routes, inter-area routes and intra-area routes respectively. The distance range is 1 to 255.

### Area Configuration

**set protocols ospfv3 area <number> range <prefix>**

This command summarizes intra area paths from specified area into one Type-3 Inter-Area Prefix LSA announced to other areas. This command can be used only in ABR.

**set protocols ospfv3 area <number> range <prefix> not-advertise**

This command instead of summarizing intra area paths filter them - i.e. intra area paths from this range are not advertised into other areas. This command makes sense in ABR only.

### Interface Configuration

**set protocols ospfv3 interface <interface> ipv6 cost <number>**

This command sets link cost for the specified interface. The cost value is set to router-LSA's metric field and used for SPF calculation. The cost range is 1 to 65535.

**set protocols ospfv3 interface <interface> dead-interval <number>**

Set number of seconds for router Dead Interval timer value used for Wait Timer and Inactivity Timer. This value must be the same for all routers attached to a common network. The default value is 40 seconds. The interval range is 1 to 65535.

**set protocols ospfv3 interface <interface> hello-interval <number>**

Set number of seconds for Hello Interval timer value. Setting this value, Hello packet will be sent every timer value seconds on the specified interface. This value must be the same for all routers attached to a common network. The default value is 10 seconds. The interval range is 1 to 65535.

**set protocols ospfv3 interface <interface> mtu-ignore**

This command disables check of the MTU value in the OSPF DBD packets. Thus, use of this command allows the OSPF adjacency to reach the FULL state even though there is an interface MTU mismatch between two OSPF routers.

**set protocols ospfv3 interface <interface> network <type>**

This command allows to specify the distribution type for the network connected to this interface:

**broadcast** – broadcast IP addresses distribution. **point-to-point** – address distribution in point-to-point networks.

**set protocols ospfv3 interface <interface> priority <number>**

This command sets Router Priority integer value. The router with the highest priority will be more eligible to become Designated Router. Setting the value to 0, makes the router ineligible to become Designated Router. The default value is 1. The interval range is 0 to 255.

**set protocols ospfv3 interface <interface> passive**

This command specifies interface as passive. Passive interface advertises its address, but does not run the OSPF protocol (adjacencies are not formed and hello packets are not generated).

**set protocols ospfv3 interface <interface> retransmit-interval <number>**

This command sets number of seconds for RxmtInterval timer value. This value is used when retransmitting Database Description and Link State Request packets if acknowledge was not received. The default value is 5 seconds. The interval range is 3 to 65535.

**set protocols ospfv3 interface <interface> transmit-delay <number>**

This command sets number of seconds for InfTransDelay value. It allows to set and adjust for each interface the delay interval before starting the synchronizing process of the router's database with all neighbors. The default value is 1 seconds. The interval range is 3 to 65535.

## Graceful Restart

**set protocols ospfv3 graceful-restart [grace-period (1-1800)]**

Configure Graceful Restart [RFC 3623](#) restarting support. When enabled, the default grace period is 120 seconds.

To perform a graceful shutdown, the FRR graceful-restart prepare ip ospf EXEC-level command needs to be issued before restarting the ospfd daemon.

**set protocols ospfv3 graceful-restart helper enable [router-id A.B.C.D]**

Configure Graceful Restart [RFC 3623](#) helper support. By default, helper support is disabled for all neighbours. This config enables/disables helper support on this router for all neighbours.

To enable/disable helper support for a specific neighbour, the router-id (A.B.C.D) has to be specified.

**set protocols ospfv3 graceful-restart helper lsa-check-disable**

By default *strict-lsa-checking* is configured then the helper will abort the Graceful Restart when a LSA change occurs which affects the restarting router.

This command disables it.

**set protocols ospfv3 graceful-restart helper supported-grace-time**

Supports as HELPER for configured grace period.

**set protocols ospfv3 graceful-restart helper planned-only**

It helps to support as HELPER only for planned restarts.

By default, it supports both planned and unplanned outages.

## Redistribution Configuration

**set protocols ospfv3 redistribute <route source>**

This command redistributes routing information from the given route source to the OSPFv3 process. There are five modes available for route source: bgp, connected, kernel, ripng, static.

**set protocols ospf redistribute <route source> route-map <name>**

This command allows to use route map to filter redistributed routes from given route source. There are five modes available for route source: bgp, connected, kernel, ripng, static.

## Operational Mode Commands

**show ipv6 ospfv3 neighbor**

This command displays the neighbors status.

**show ipv6 ospfv3 neighbor detail**

This command displays the neighbors information in a detailed form, not just a summary table.

**show ipv6 ospfv3 neighbor drchoice**

This command displays the neighbor DR choice information.

**show ipv6 ospfv3 interface [prefix] | [<interface> [prefix]]**

This command displays state and configuration of OSPF the specified interface, or all interfaces if no interface is given. With the argument `prefix` this command shows connected prefixes to advertise.

**show ipv6 ospfv3 route**

This command displays the OSPF routing table, as determined by the most recent SPF calculation.

**show ipv6 ospfv3 border-routers**

This command displays a table of paths to area boundary and autonomous system boundary routers.

**show ipv6 ospfv3 database**

This command displays a summary table with a database contents (LSA).

**show ipv6 ospfv3 database <type> [A.B.C.D] [adv-router <A.B.C.D>|self-originate]**

This command displays a database contents for a specific link advertisement type.

**show ipv6 ospfv3 redistribute**

This command displays external information redistributed into OSPFv3

## Configuration Example

A typical configuration using 2 nodes.

### Node 1:

```
set protocols ospfv3 interface eth1 area 0.0.0.0
set protocols ospfv3 area 0.0.0.0 range 2001:db8:1::/64
set protocols ospfv3 parameters router-id 192.168.1.1
set protocols ospfv3 redistribute connected
```

### Node 2:

```
set protocols ospfv3 interface eth1 area 0.0.0.0
set protocols ospfv3 area 0.0.0.0 range 2001:db8:2::/64
set protocols ospfv3 parameters router-id 192.168.2.1
set protocols ospfv3 redistribute connected
```

### To see the redistributed routes:

```
show ipv6 ospfv3 redistribute
```

**Bemerkung:** You cannot easily redistribute IPv6 routes via OSPFv3 on a WireGuard interface link. This requires you to configure link-local addresses manually on the WireGuard interfaces, see [T1483](#).

Example configuration for WireGuard interfaces:

### Node 1

```
set interfaces wireguard wg01 address 'fe80::216:3eff:fe51:fd8c/64'
set interfaces wireguard wg01 address '192.168.0.1/24'
set interfaces wireguard wg01 peer ospf02 allowed-ips '::/0'
set interfaces wireguard wg01 peer ospf02 allowed-ips '0.0.0.0/0'
set interfaces wireguard wg01 peer ospf02 endpoint '10.1.1.101:12345'
set interfaces wireguard wg01 peer ospf02 pubkey 'ie3...='
set interfaces wireguard wg01 port '12345'
set protocols ospfv3 parameters router-id 192.168.1.1
set protocols ospfv3 interface 'wg01' area 0.0.0.0
set protocols ospfv3 interface 'lo' area 0.0.0.0
```

### Node 2

```
set interfaces wireguard wg01 address 'fe80::216:3eff:fe0a:7ada/64'
set interfaces wireguard wg01 address '192.168.0.2/24'
set interfaces wireguard wg01 peer ospf01 allowed-ips '::/0'
set interfaces wireguard wg01 peer ospf01 allowed-ips '0.0.0.0/0'
set interfaces wireguard wg01 peer ospf01 endpoint '10.1.1.100:12345'
set interfaces wireguard wg01 peer ospf01 pubkey 'NHI...='
set interfaces wireguard wg01 port '12345'
set protocols ospfv3 parameters router-id 192.168.1.2
set protocols ospfv3 interface 'wg01' area 0.0.0.0
set protocols ospfv3 interface 'lo' area 0.0.0.0
```

### Status

```
vyos@ospf01:~$ sh ipv6 ospfv3 neighbor
Neighbor ID      Pri    DeadTime    State/IfState    Duration I/F[State]
192.168.0.2      1      00:00:37    Full/PointToPoint 00:18:03 wg01[PointToPoint]

vyos@ospf02# run sh ipv6 ospfv3 neighbor
Neighbor ID      Pri    DeadTime    State/IfState    Duration I/F[State]
192.168.0.1      1      00:00:39    Full/PointToPoint 00:19:44 wg01[PointToPoint]
```

### 8.9.10 PIM – Protocol Independent Multicast

VyOS supports PIM-SM (PIM Sparse Mode) as well as IGMP v2 and v3

PIM (Protocol Independent Multicast) must be configured in every interface of every participating router. Every router must also have the location of the Rendezvous Point manually configured. Then, unidirectional shared trees rooted at the Rendezvous Point will automatically be built for multicast distribution.

Traffic from multicast sources will go to the Rendezvous Point, and receivers will pull it from a shared tree using IGMP.

Multicast receivers will talk IGMP to their local router, so, besides having PIM configured in every router, IGMP must also be configured in any router where there could be a multicast receiver locally connected.

VyOS supports both IGMP version 2 and version 3 (which allows source-specific multicast).

#### PIM-SM - PIM Sparse Mode

##### **set protocols pim ecmp**

If PIM has the a choice of ECMP nexthops for a particular RPF (Reverse Path Forwarding), PIM will cause S,G flows to be spread out amongst the nexthops. If this command is not specified then the first nexthop found will be used.

##### **set protocols pim ecmp rebalance**

If PIM is using ECMP and an interface goes down, cause PIM to rebalance all S,G flows across the remaining nexthops. If this command is not configured PIM only modifies those S,G flows that were using the interface that went down.

##### **set protocols pim join-prune-interval <n>**

Modify the join/prune interval that PIM uses to the new value. Time is specified in seconds.

The default time is 60 seconds.

If you enter a value smaller than 60 seconds be aware that this can and will affect convergence at scale.

##### **set protocols pim keep-alive-timer <n>**

Modify the time out value for a S,G flow from 1-65535 seconds. If choosing a value below 31 seconds be aware that some hardware platforms cannot see data flowing in better than 30 second chunks.

##### **set protocols pim packets <n>**

When processing packets from a neighbor process the number of packets incoming at one time before moving on to the next task.

The default value is 3 packets.

This command is only useful at scale when you can possibly have a large number of PIM control packets flowing.

##### **set protocols pim register-accept-list <prefix-list>**

When PIM receives a register packet the source of the packet will be compared to the prefix-list specified, and if a permit is received normal processing continues. If a deny is returned for the source address of the register packet a register stop message is sent to the source.

**set protocols pim register-suppress-time <n>**

Modify the time that pim will register suppress a FHR will send register notifications to the kernel.

**set protocols pim rp <address> group <group>**

In order to use PIM, it is necessary to configure a RP (Rendezvous Point) for join messages to be sent to. Currently the only methodology to do this is via static rendezvous point commands.

All routers in the PIM network must agree on these values.

The first ip address is the RP's address and the second value is the matching prefix of group ranges covered.

**set protocols pim rp keep-alive-timer <n>**

Modify the time out value for a S,G flow from 1-65535 seconds at RP. The normal keepalive period for the KAT(S,G) defaults to 210 seconds. However, at the RP, the keepalive period must be at least the Register\_Suppression\_Time, or the RP may time out the (S,G) state before the next Null-Register arrives. Thus, the KAT(S,G) is set to max(Keepalive\_Period, RP\_Keepalive\_Period) when a Register-Stop is sent.

If choosing a value below 31 seconds be aware that some hardware platforms cannot see data flowing in better than 30 second chunks.

See [RFC 7761#section-4.1](#) for details.

**set protocols pim no-v6-secondary**

When sending PIM hello packets tell PIM to not send any v6 secondary addresses on the interface. This information is used to allow PIM to use v6 nexthops in it's decision for RPF lookup if this option is not set (default).

**set protocols pim spt-switchover infinity-and-beyond [prefix-list <list>]**

On the last hop router if it is desired to not switch over to the SPT tree configure this command.

Optional parameter prefix-list can be use to control which groups to switch or not switch. If a group is PERMIT as per the prefix-list, then the SPT switchover does not happen for it and if it is DENY, then the SPT switchover happens.

**set protocols pim ssm prefix-list <list>**

Specify a range of group addresses via a prefix-list that forces PIM to never do SSM over.

## Interface specific commands

**set protocols pim interface <interface> bfd [profile <name>]**

Automatically create BFD session for each RIP peer discovered in this interface. When the BFD session monitor signalize that the link is down the RIP peer is removed and all the learned routes associated with that peer are removed.

If optional profile parameter is used, select a BFD profile for the BFD sessions created via this interface.

**set protocols pim interface <interface> dr-priority <n>**

Set the DR (Designated Router) Priority for the interface. This command is useful to allow the user to influence what node becomes the DR for a LAN segment.

**set protocols pim interface <interface> hello <n>**

Set the PIM hello and hold interval for a interface.

```
set protocols pim interface <interface> no-bsm
```

Tell PIM that we would not like to use this interface to process bootstrap messages.

```
set protocols pim interface <interface> no-unicast-bsm
```

Tell PIM that we would not like to use this interface to process unicast bootstrap messages.

```
set protocols pim interface <interface> passive
```

Disable sending and receiving PIM control packets on the interface.

```
set protocols pim interface <interface> source-address <ip-address>
```

If you have multiple addresses configured on a particular interface and would like PIM to use a specific source address associated with that interface.

## IGMP - Internet Group Management Protocol)

```
set protocols pim igmp watermark-warning <n>
```

Configure watermark warning generation for an IGMP group limit. Generates warning once the configured group limit is reached while adding new groups.

## Interface specific commands

```
set protocols pim interface <interface> igmp join <multicast-address> source-address <IP-address>
```

Use this command to allow the selected interface to join a multicast group defining the multicast address you want to join and the source IP address too.

```
set protocols pim interface <interface> igmp query-interval <seconds>
```

Use this command to configure in the selected interface the IGMP host query interval (1-1800) in seconds that PIM will use.

```
set protocols pim interface <interface> igmp query-max-response-time <n>
```

Use this command to configure in the selected interface the IGMP query response timeout value (10-250) in deciseconds. If a report is not returned in the specified time, it will be assumed the (S,G) or (\*,G) state [RFC 7761#section-4.1](#) has timed out.

```
set protocols pim interface <interface> igmp version <version-number>
```

Use this command to define in the selected interface whether you choose IGMP version 2 or 3.

The default value is 3.

## Example

In the following example we can see a basic multicast setup:

### Router 1

```
set interfaces ethernet eth2 address '172.16.0.2/24'
set interfaces ethernet eth1 address '100.64.0.1/24'
set protocols ospf area 0 network '172.16.0.0/24'
set protocols ospf area 0 network '100.64.0.0/24'
set protocols igmp interface eth1
set protocols pim interface eth1
set protocols pim interface eth2
set protocols pim rp address 172.16.255.1 group '224.0.0.0/4'
```

### Router 3

```
set interfaces dummy dum0 address '172.16.255.1/24'
set interfaces ethernet eth0 address '172.16.0.1/24'
set interfaces ethernet eth1 address '172.16.1.1/24'
set protocols ospf area 0 network '172.16.0.0/24'
set protocols ospf area 0 network '172.16.255.0/24'
set protocols ospf area 0 network '172.16.1.0/24'
set protocols pim interface dum0
set protocols pim interface eth0
set protocols pim interface eth1
set protocols pim rp address 172.16.255.1 group '224.0.0.0/4'
```

### Router 2

```
set interfaces ethernet eth1 address '10.0.0.1/24'
set interfaces ethernet eth2 address '172.16.1.2/24'
set protocols ospf area 0 network '10.0.0.0/24'
set protocols ospf area 0 network '172.16.1.0/24'
set protocols pim interface eth1
set protocols pim interface eth2
set protocols pim rp address 172.16.255.1 group '224.0.0.0/4'
```

### 8.9.11 PIM6 - Protocol Independent Multicast for IPv6

VyOS facilitates IPv6 Multicast by supporting **PIMv6** and **MLD**.

PIMv6 (Protocol Independent Multicast for IPv6) must be configured in every interface of every participating router. Every router must also have the location of the Rendezvous Point manually configured. Then, unidirectional shared trees rooted at the Rendezvous Point will automatically be built for multicast distribution.

Traffic from multicast sources will go to the Rendezvous Point, and receivers will pull it from a shared tree using MLD (Multicast Listener Discovery).

Multicast receivers will talk MLD to their local router, so, besides having PIMv6 configured in every router, MLD must also be configured in any router where there could be a multicast receiver locally connected.

VyOS supports both MLD version 1 and version 2 (which allows source-specific multicast).

#### Basic commands

These are the commands for a basic setup.

```
set protocols pim6 interface <interface-name>
```

Use this command to enable PIMv6 in the selected interface so that it can communicate with PIMv6 neighbors.

This command also enables MLD reports and query on the interface unless `mld disable` is configured.

```
set protocols pim6 interface <interface-name> mld disable
```

Disable MLD reports and query on the interface.

#### Tuning commands

You can also tune multicast with the following commands.

```
set protocols pim6 interface <interface-name> mld interval <seconds>
```

Use this command to configure in the selected interface the MLD host query interval (1-65535) in seconds that PIM will use. The default value is 125 seconds.

```
set protocols pim6 interface <interface-name> mld join <multicast-address>
```

Use this command to allow the selected interface to join a multicast group.

```
set protocols pim6 interface <interface-name> mld join <multicast-address> source  
<source-address>
```

Use this command to allow the selected interface to join a source-specific multicast group.

```
set protocols pim6 interface <interface-name> mld last-member-query-count <count>
```

Set the MLD last member query count. The default value is 2.

```
set protocols pim6 interface <interface-name> mld last-member-query-interval  
<milliseconds>
```

Set the MLD last member query interval in milliseconds (100-6553500). The default value is 1000 milliseconds.

```
set protocols pim6 interface <interface-name> mld max-response-time <milliseconds>
```

Set the MLD query response timeout in milliseconds (100-6553500). The default value is 10000 milliseconds.

```
set protocols pim6 interface <interface-name> mld version <version-number>
```

Set the MLD version used on this interface. The default value is 2.

## Configuration Example

To enable MLD reports and query on interfaces *eth0* and *eth1*:

```
set protocols pim6 interface eth0
set protocols pim6 interface eth1
```

The following configuration explicitly joins multicast group *ff15::1234* on interface *eth1* and source-specific multicast group *ff15::5678* with source address *2001:db8::1* on interface *eth1*:

```
set protocols pim6 interface eth0 mld join ff15::1234
set protocols pim6 interface eth1 mld join ff15::5678 source 2001:db8::1
```

## 8.9.12 RIP

RIP (Routing Information Protocol) is a widely deployed interior gateway protocol. RIP was developed in the 1970s at Xerox Labs as part of the XNS routing protocol. RIP is a distance-vector protocol and is based on the Bellman-Ford algorithms. As a distance-vector protocol, RIP router send updates to its neighbors periodically, thus allowing the convergence to a known topology. In each update, the distance to any given network will be broadcast to its neighboring router.

Supported versions of RIP are:

- RIPv1 as described in [RFC 1058](#)
- RIPv2 as described in [RFC 2453](#)

### General Configuration

**set protocols rip network <A.B.C.D/M>**

This command enables RIP and sets the RIP enable interface by NETWORK. The interfaces which have addresses matching with NETWORK are enabled.

**set protocols rip interface <interface>**

This command specifies a RIP enabled interface by interface name. Both the sending and receiving of RIP packets will be enabled on the port specified in this command.

**set protocols rip neighbor <A.B.C.D>**

This command specifies a RIP neighbor. When a neighbor doesn't understand multicast, this command is used to specify neighbors. In some cases, not all routers will be able to understand multicasting, where packets are sent to a network or a group of addresses. In a situation where a neighbor cannot process multicast packets, it is necessary to establish a direct link between routers.

**set protocols rip passive-interface interface <interface>**

This command sets the specified interface to passive mode. On passive mode interface, all receiving packets are processed as normal and VyOS does not send either multicast or unicast RIP packets except to RIP neighbors specified with neighbor command.

**set protocols rip passive-interface interface default**

This command specifies all interfaces to passive mode.

## Optional Configuration

### **set protocols rip default-distance <distance>**

This command change the distance value of RIP. The distance range is 1 to 255.

---

**Bemerkung:** Routes with a distance of 255 are effectively disabled and not installed into the kernel.

---

### **set protocols rip network-distance <A.B.C.D/M> distance <distance>**

This command sets default RIP distance to a specified value when the routes source IP address matches the specified prefix.

### **set protocols rip network-distance <A.B.C.D/M> access-list <name>**

This command can be used with previous command to sets default RIP distance to specified value when the route source IP address matches the specified prefix and the specified access-list.

### **set protocols rip default-information originate**

This command generate a default route into the RIP.

### **set protocols rip distribute-list access-list <in|out> <number>**

This command can be used to filter the RIP path using access lists. in and out this is the direction in which the access lists are applied.

### **set protocols rip distribute-list interface <interface> access-list <in|out> <number>**

This command allows you apply access lists to a chosen interface to filter the RIP path.

### **set protocols rip distribute-list prefix-list <in|out> <name>**

This command can be used to filter the RIP path using prefix lists. in and out this is the direction in which the prefix lists are applied.

### **set protocols rip distribute-list interface <interface> prefix-list <in|out> <name>**

This command allows you apply prefix lists to a chosen interface to filter the RIP path.

### **set protocols rip route <A.B.C.D/M>**

This command is specific to FRR and VyOS. The route command makes a static route only inside RIP. This command should be used only by advanced users who are particularly knowledgeable about the RIP protocol. In most cases, we recommend creating a static route in VyOS and redistributing it in RIP using `redistribute static`.

### **set protocols rip timers update <seconds>**

This command specifies the update timer. Every update timer seconds, the RIP process is awakened to send an unsolicited response message containing the complete routing table to all neighboring RIP routers. The time range is 5 to 2147483647. The default value is 30 seconds.

### **set protocols rip timers timeout <seconds>**

This command specifies the timeout timer. Upon expiration of the timeout, the route is no longer valid; however, it is retained in the routing table for a short time so that neighbors can be notified that the route has been dropped. The time range is 5 to 2147483647. The default value is 180 seconds.

### **set protocols rip timers garbage-collection <seconds>**

This command specifies the garbage-collection timer. Upon expiration of the garbage-collection timer, the route is finally removed from the routing table. The time range is 5 to 2147483647. The default value is 120 seconds.

## Redistribution Configuration

### **set protocols rip redistribute <route source>**

This command redistributes routing information from the given route source into the RIP tables. There are five modes available for route source: bgp, connected, kernel, ospf, static.

### **set protocols rip redistribute <route source> metric <metric>**

This command specifies metric for redistributed routes from the given route source. There are five modes available for route source: bgp, connected, kernel, ospf, static. The metric range is 1 to 16.

### **set protocols rip redistribute <route source> route-map <name>**

This command allows to use route map to filter redistributed routes from the given route source. There are five modes available for route source: bgp, connected, kernel, ospf, static.

### **set protocols rip default-metric <metric>**

This command modifies the default metric (hop count) value for redistributed routes. The metric range is 1 to 16. The default value is 1. This command does not affect connected route even if it is redistributed by redistribute connected. To modify connected routes metric value, please use redistribute connected metric.

## Interfaces Configuration

### **set interfaces <inttype> <intname> ip rip authentication plaintext-password <text>**

This command sets the interface with RIP simple password authentication. This command also sets authentication string. The string must be shorter than 16 characters.

### **set interfaces <inttype> <intname> ip rip authentication md5 <id> password <text>**

This command sets the interface with RIP MD5 authentication. This command also sets MD5 Key. The key must be shorter than 16 characters.

### **set interfaces <inttype> <intname> ip rip split-horizon disable**

This command disables split-horizon on the interface. By default, VyOS does not advertise RIP routes out the interface over which they were learned (split horizon).<sup>3</sup>

### **set interfaces <inttype> <intname> ip rip split-horizon poison-reverse**

This command enables poison-reverse on the interface. If both poison reverse and split horizon are enabled, then VyOS advertises the learned routes as unreachable over the interface on which the route was learned.

## Operational Mode Commands

### **show ip rip**

This command displays RIP routes.

Codes: R - RIP, C - connected, S - Static, O - OSPF, B - BGP

Sub-codes:

(n) - normal, (s) - static, (d) - default, (r) - redistribute,  
(i) - interface

	Network	Next Hop	Metric From	Tag Time
C(i)	10.0.12.0/24	0.0.0.0	1 self	0
C(i)	10.0.13.0/24	0.0.0.0	1 self	0
R(n)	10.0.23.0/24	10.0.12.2	2 10.0.12.2	0 02:53

**show ip rip status**

The command displays current RIP status. It includes RIP timer, filtering, version, RIP enabled interface and RIP peer information.

```
Routing Protocol is "rip"
  Sending updates every 30 seconds with +/-50%, next due in 11 seconds
  Timeout after 180 seconds, garbage collect after 120 seconds
  Outgoing update filter list for all interface is not set
  Incoming update filter list for all interface is not set
  Default redistribution metric is 1
  Redistributing:
  Default version control: send version 2, receive any version
    Interface      Send  Recv  Key-chain
    eth0           2     1 2
    eth2           2     1 2
  Routing for Networks:
    10.0.12.0/24
    eth0
  Routing Information Sources:
    Gateway          BadPackets  BadRoutes  Distance  Last Update
    10.0.12.2         0           0          120      00:00:11
  Distance: (default is 120)
```

**Configuration Example**

Simple RIP configuration using 2 nodes and redistributing connected interfaces.

**Node 1:**

```
set interfaces loopback address 10.1.1.1/32
set protocols rip network 192.168.0.0/24
set protocols rip redistribute connected
```

**Node 2:**

```
set interfaces loopback address 10.2.2.2/32
set protocols rip network 192.168.0.0/24
set protocols rip redistribute connected
```

**8.9.13 RPKI**

There are two types of Network Admins who deal with BGP, those who have created an international incident and/or outage, and those who are lying

—tweet by EvilMog, 2020-02-21

RPKI (Resource Public Key Infrastructure) is a framework designed to secure the Internet routing infrastructure. It associates BGP route announcements with the correct originating ASN which BGP routers can then use to check each route against the corresponding ROA (Route Origin Authorisation) for validity. RPKI is described in [RFC 6480](#).

A BGP-speaking router like VyOS can retrieve ROA information from RPKI „Relying Party software“ (often just called an „RPKI server“ or „RPKI validator“) by using RTR (RPKI to Router) protocol. There are several open source implementations to choose from, such as NLNetLabs' [Routinator](#) (written in Rust), OpenBSD's [rpki-client](#) (written in C), and [StayRTR](#) (written in Go). The RTR protocol is described in [RFC 8210](#).

**Tipp:** If you are new to these routing security technologies then there is an [excellent guide to RPKI](#) by NLnet Labs which will get you up to speed very quickly. Their documentation explains everything from what RPKI is to deploying it in production. It also has some [help and operational guidance](#) including „What can I do about my route having an Invalid state?“

---

## Getting started

First you will need to deploy an RPKI validator for your routers to use. NLnet Labs provides a collection of [software](#) you can compare and settle on one. Once your server is running you can start validating announcements.

Imported prefixes during the validation may have values:

### **valid**

The prefix and ASN that originated it match a signed ROA. These are probably trustworthy route announcements.

### **invalid**

The prefix or prefix length and ASN that originated it doesn't match any existing ROA. This could be the result of a prefix hijack, or merely a misconfiguration, but should probably be treated as un-trustworthy route announcements.

### **notfound**

No ROA exists which covers that prefix. Unfortunately this is the case for about 40%-50% of the prefixes which were announced to the DFZ (default-free zone) at the start of 2024.

---

**Bemerkung:** If you are responsible for the global addresses assigned to your network, please make sure that your prefixes have ROAs associated with them to avoid being *notfound* by RPKI. For most ASNs this will involve publishing ROAs via your RIR (Regional Internet Registry) (RIPE NCC, APNIC, ARIN, LACNIC, or AFRINIC), and is something you are encouraged to do whenever you plan to announce addresses into the DFZ.

Particularly large networks may wish to run their own RPKI certificate authority and publication server instead of publishing ROAs via their RIR. This is a subject far beyond the scope of VyOS' documentation. Consider reading about [Krill](#) if this is a rabbit hole you need or especially want to dive down.

---

## Features of the Current Implementation

In a nutshell, the current implementation provides the following features:

- The BGP router can connect to one or more RPKI cache servers to receive validated prefix to origin AS mappings. Advanced failover can be implemented by server sockets with different preference values.
- If no connection to an RPKI cache server can be established after a pre-defined timeout, the router will process routes without prefix origin validation. It still will try to establish a connection to an RPKI cache server in the background.
- By default, enabling RPKI does not change best path selection. In particular, invalid prefixes will still be considered during best path selection. However, the router can be configured to ignore all invalid prefixes.
- Route maps can be configured to match a specific RPKI validation state. This allows the creation of local policies, which handle BGP routes based on the outcome of the Prefix Origin Validation.
- Updates from the RPKI cache servers are directly applied and path selection is updated accordingly. (Soft reconfiguration must be enabled for this to work).

## Configuration

**set protocols rpki polling-period <1-86400>**

Define the time interval to update the local cache

The default value is 300 seconds.

**set protocols rpki expire-interval <600-172800>**

Set the number of seconds the router waits until the router expires the cache.

The default value is 7200 seconds.

**set protocols rpki retry-interval <1-7200>**

Set the number of seconds the router waits until retrying to connect to the cache server.

The default value is 600 seconds.

**set protocols rpki cache <address> port <port>**

Defined the IPv4, IPv6 or FQDN and port number of the caching RPKI caching instance which is used.

This is a mandatory setting.

**set protocols rpki cache <address> preference <preference>**

Multiple RPKI caching instances can be supplied and they need a preference in which their result sets are used.

This is a mandatory setting.

## SSH

Connections to the RPKI caching server can not only be established by TCP using the RTR protocol but you can also rely on a secure SSH session to the server. This provides transport integrity and confidentiality and it is a good idea if your validation software supports it. To enable SSH, first you need to create an SSH client keypair using **generate ssh client-key /config/auth/id\_rsa\_rpki**. Once your key is created you can setup the connection.

**set protocols rpki cache <address> ssh username <user>**

SSH username to establish an SSH connection to the cache server.

**set protocols rpki cache <address> ssh private-key-file <filepath>**

Local path that includes the private key file of the router.

**set protocols rpki cache <address> ssh public-key-file <filepath>**

Local path that includes the public key file of the router.

---

**Bemerkung:** When using SSH, private-key-file and public-key-file are mandatory options.

---

## Example

We can build route-maps for import based on these states. Here is a simple RPKI configuration, where *routinator* is the RPKI-validating „cache“ server with ip *192.0.2.1*:

```
set protocols rpki cache 192.0.2.1 port '3323'
set protocols rpki cache 192.0.2.1 preference '1'
```

Here is an example route-map to apply to routes learned at import. In this filter we reject prefixes with the state *invalid*, and set a higher *local-preference* if the prefix is RPKI *valid* rather than merely *notfound*.

```
set policy route-map ROUTES-IN rule 10 action 'permit'
set policy route-map ROUTES-IN rule 10 match rpki 'valid'
set policy route-map ROUTES-IN rule 10 set local-preference '300'
set policy route-map ROUTES-IN rule 20 action 'permit'
set policy route-map ROUTES-IN rule 20 match rpki 'notfound'
set policy route-map ROUTES-IN rule 20 set local-preference '125'
set policy route-map ROUTES-IN rule 30 action 'deny'
set policy route-map ROUTES-IN rule 30 match rpki 'invalid'
```

Once your routers are configured to reject RPKI-invalid prefixes, you can test whether the configuration is working correctly using Cloudflare's [test](#) website. Keep in mind that in order for this to work, you need to have no default routes or anything else that would still send traffic to RPKI-invalid destinations.

## 8.9.14 Static

Static routes are manually configured routes, which, in general, cannot be updated dynamically from information VyOS learns about the network topology from other routing protocols. However, if a link fails, the router will remove routes, including static routes, from the RIPB (Routing Information Base) that used this interface to reach the next hop. In general, static routes should only be used for very simple network topologies, or to override the behavior of a dynamic routing protocol for a small number of routes. The collection of all routes the router has learned from its configuration or from its dynamic routing protocols is stored in the RIB. Unicast routes are directly used to determine the forwarding table used for unicast packet forwarding.

### Static Routes

**set protocols static route <subnet> next-hop <address>**

Configure next-hop <address> for an IPv4 static route. Multiple static routes can be created.

**set protocols static route <subnet> next-hop <address> disable**

Disable this IPv4 static route entry.

**set protocols static route <subnet> next-hop <address> distance <distance>**

Defines next-hop distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

Range is 1 to 255, default is 1.

---

**Bemerkung:** Routes with a distance of 255 are effectively disabled and not installed into the kernel.

---

**set protocols static route6 <subnet> next-hop <address>**

Configure next-hop *<address>* for an IPv6 static route. Multiple static routes can be created.

```
set protocols static route6 <subnet> next-hop <address> disable
```

Disable this IPv6 static route entry.

```
set protocols static route6 <subnet> next-hop <address> distance <distance>
```

Defines next-hop distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

Range is 1 to 255, default is 1.

---

**Bemerkung:** Routes with a distance of 255 are effectively disabled and not installed into the kernel.

---

```
set protocols static route6 <subnet> next-hop <address> segments <segments>
```

It is possible to specify a static route for ipv6 prefixes using an SRv6 segments instruction. The / separator can be used to specify multiple segment instructions.

Example:

```
set protocols static route6 2001:db8:1000::/36 next-hop 2001:db8:201::ffff segments
→ '2001:db8:aaaa::7/2002::4/2002::3/2002::2'
```

```
vyos@vyos:~$ show ipv6 route
Codes: K - kernel route, C - connected, S - static, R - RIPng,
       O - OSPFv3, I - IS-IS, B - BGP, N - NHRP, T - Table,
       v - VNC, V - VNC-Direct, A - Babel, F - PBR,
       f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup
       t - trapped, o - offload failure
C>* 2001:db8:201::/64 is directly connected, eth0.201, 00:00:46
S>* 2001:db8:1000::/36 [1/0] via 2001:db8:201::ffff, eth0.201, seg6
→2001:db8:aaaa::7,2002::4,2002::3,2002::2, weight 1, 00:00:08
```

## Interface Routes

```
set protocols static route <subnet> interface <interface>
```

Allows you to configure the next-hop interface for an interface-based IPv4 static route. *<interface>* will be the next-hop interface where traffic is routed for the given *<subnet>*.

```
set protocols static route <subnet> interface <interface> disable
```

Disables interface-based IPv4 static route.

```
set protocols static route <subnet> interface <interface> distance <distance>
```

Defines next-hop distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

Range is 1 to 255, default is 1.

```
set protocols static route6 <subnet> interface <interface>
```

Allows you to configure the next-hop interface for an interface-based IPv6 static route. *<interface>* will be the next-hop interface where traffic is routed for the given *<subnet>*.

**set protocols static route6 <subnet> interface <interface> disable**

Disables interface-based IPv6 static route.

**set protocols static route6 <subnet> interface <interface> distance <distance>**

Defines next-hop distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

Range is 1 to 255, default is 1.

**set protocols static route6 <subnet> interface <interface> segments <segments>**

It is possible to specify a static route for ipv6 prefixes using an SRv6 segments instruction. The / separator can be used to specify multiple segment instructions.

Example:

```
set protocols static route6 2001:db8:1000::/36 interface eth0 segments
↔ '2001:db8:aaaa::7/2002::4/2002::3/2002::2'
```

## Blackhole

**set protocols static route <subnet> blackhole**

Use this command to configure a „black-hole“ route on the router. A black-hole route is a route for which the system silently discard packets that are matched. This prevents networks leaking out public interfaces, but it does not prevent them from being used as a more specific route inside your network.

**set protocols static route <subnet> blackhole distance <distance>**

Defines blackhole distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

**set protocols static route6 <subnet> blackhole**

Use this command to configure a „black-hole“ route on the router. A black-hole route is a route for which the system silently discard packets that are matched. This prevents networks leaking out public interfaces, but it does not prevent them from being used as a more specific route inside your network.

**set protocols static route6 <subnet> blackhole distance <distance>**

Defines blackhole distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

## Alternate Routing Tables

TBD

Alternate routing tables are used with policy based routing by utilizing [VRF](#).

### 8.9.15 ARP

ARP (Address Resolution Protocol) is a communication protocol used for discovering the link layer address, such as a MAC address, associated with a given internet layer address, typically an IPv4 address. This mapping is a critical function in the Internet protocol suite. ARP was defined in 1982 by [RFC 826](#) which is Internet Standard STD 37.

In Internet Protocol Version 6 (IPv6) networks, the functionality of ARP is provided by the Neighbor Discovery Protocol (NDP).

To manipulate or display [ARP](#) table entries, the following commands are implemented.

#### Configure

**set protocols static arp interface <interface> address <host> mac <mac>**

This will configure a static ARP entry always resolving <address> to <mac> for interface <interface>.

Example:

```
set protocols static arp interface eth0 address 192.0.2.1 mac 01:23:45:67:89:01
```

#### Operation

**show protocols static arp**

Display all known ARP table entries spanning across all interfaces

```
vyos@vyos:~$ show protocols static arp
Address           HWtype  HWaddress      Flags Mask    Iface
10.1.1.1          ether    00:53:00:de:23:2e  C             eth1
10.1.1.100        ether    00:53:00:de:23:aa  CM            eth1
```

**show protocols static arp interface eth1**

Display all known ARP table entries on a given interface only (*eth1*):

```
vyos@vyos:~$ show protocols static arp interface eth1
Address           HWtype  HWaddress      Flags Mask    Iface
10.1.1.1          ether    00:53:00:de:23:2e  C             eth1
10.1.1.100        ether    00:53:00:de:23:aa  CM            eth1
```

## 8.10 Service

### 8.10.1 UDP Broadcast Relay

Certain vendors use broadcasts to identify their equipment within one ethernet segment. Unfortunately if you split your network with multiple VLANs you loose the ability of identifying your equipment.

This is where „UDP broadcast relay“ comes into play! It will forward received broadcasts to other configured networks.

Every UDP port which will be forward requires one unique ID. Currently we support 99 IDs!

## Configuration

**set service broadcast-relay id <n> description <description>**

A description can be added for each and every unique relay ID. This is useful to distinguish between multiple different ports/applications.

**set service broadcast-relay id <n> interface <interface>**

The interface used to receive and relay individual broadcast packets. If you want to receive/relay packets on both *eth1* and *eth2* both interfaces need to be added.

**set service broadcast-relay id <n> address <ipv4-address>**

Set the source IP of forwarded packets, otherwise original senders address is used.

**set service broadcast-relay id <n> port <port>**

The UDP port number used by your application. It is mandatory for this kind of operation.

**set service broadcast-relay id <n> disable**

Each broadcast relay instance can be individually disabled without deleting the configured node by using the following command:

**set service broadcast-relay disable**

In addition you can also disable the whole service without the need to remove it from the current configuration.

---

**Bemerkung:** You can run the UDP broadcast relay service on multiple routers connected to a subnet. There is **NO** UDP broadcast relay packet storm!

---

## Example

To forward all broadcast packets received on *UDP port 1900* on *eth3*, *eth4* or *eth5* to all other interfaces in this configuration.

```
set service broadcast-relay id 1 description 'SONOS'
set service broadcast-relay id 1 interface 'eth3'
set service broadcast-relay id 1 interface 'eth4'
set service broadcast-relay id 1 interface 'eth5'
set service broadcast-relay id 1 port '1900'
```

## 8.10.2 Config Sync

Configuration synchronization (config sync) is a feature of VyOS that permits synchronization of the configuration of one VyOS router to another in a network.

The main benefit to configuration synchronization is that it eliminates having to manually replicate configuration changes made on the primary router to the secondary (replica) router.

The writing of the configuration to the secondary router is performed through the VyOS HTTP API. The user can specify which portion(s) of the configuration will be synchronized and the mode to use - whether to replace or add.

To prevent issues with divergent configurations between the pair of routers, synchronization is strictly unidirectional from primary to replica. Both routers should be online and run the same version of VyOS.

## Configuration

**set service config-sync secondary <address|key|timeout|port>**

Specify the address, API key, timeout and port of the secondary router. You need to enable and configure the HTTP API service on the secondary router for config sync to operate.

**set service config-sync section <section>**

Specify the section of the configuration to synchronize. If more than one section is to be synchronized, repeat the command to add additional sections as required.

**set service config-sync mode <load|set>**

Two options are available for *mode*: either *load* and replace or *set* the configuration section.

Supported options for <section> include:

```
firewall
interfaces <interface>
nat
nat66
pki
policy
protocols <protocol>
qos <interface|policy>
service <service>
system <comtrack|
flow-accounting|option|sflow|static-host-mapping|sysctl|time-zone>
vpn
vrf
```

## Example

- Synchronize the time-zone and OSPF configuration from Router A to Router B
- The address of Router B is 10.0.20.112 and the port used is 8443

Configure the HTTP API service on Router B

```
set service https listen-address '10.0.20.112'
set service https port '8443'
set service https api keys id KID key 'foo'
```

Configure the config-sync service on Router A

```
set service config-sync mode 'load'
set service config-sync secondary address '10.0.20.112'
set service config-sync secondary port '8443'
set service config-sync secondary key 'foo'
set service config-sync section protocols 'ospf'
set service config-sync section system 'time-zone'
```

Make config-sync relevant changes to Router A's configuration

```
vyos@vyos-A# set system time-zone 'America/Los_Angeles'
vyos@vyos-A# commit
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
INFO:vyos_config_sync:Config synchronization: Mode=load,
Secondary=10.0.20.112
vyos@vyos-A# save

vyos@vyos-A# set protocols ospf area 0 network '10.0.48.0/30'
vyos@vyos-A# commit
INFO:vyos_config_sync:Config synchronization: Mode=load,
Secondary=10.0.20.112
vyos@vyos-A# save
```

Verify configuration changes have been replicated to Router B

```
vyos@vyos-B:~$ show configuration commands | match time-zone
set system time-zone 'America/Los_Angeles'

vyos@vyos-B:~$ show configuration commands | match ospf
set protocols ospf area 0 network '10.0.48.0/30'
```

### Known issues

Configuration resynchronization. With the current implementation of *service config-sync*, the secondary node must be online.

### 8.10.3 Conntrack Sync

One of the important features built on top of the Netfilter framework is connection tracking. Connection tracking allows the kernel to keep track of all logical network connections or sessions, and thereby relate all of the packets which may make up that connection. NAT relies on this information to translate all related packets in the same way, and iptables can use this information to act as a stateful firewall.

The connection state however is completely independent of any upper-level state, such as TCP's or SCTP's state. Part of the reason for this is that when merely forwarding packets, i.e. no local delivery, the TCP engine may not necessarily be invoked at all. Even connectionless-mode transmissions such as UDP, IPsec (AH/ESP), GRE and other tunneling protocols have, at least, a pseudo connection state. The heuristic for such protocols is often based upon a preset timeout value for inactivity, after whose expiration a Netfilter connection is dropped.

Each Netfilter connection is uniquely identified by a (layer-3 protocol, source address, destination address, layer-4 protocol, layer-4 key) tuple. The layer-4 key depends on the transport protocol; for TCP/UDP it is the port numbers, for tunnels it can be their tunnel ID, but otherwise is just zero, as if it were not part of the tuple. To be able to inspect the TCP port in all cases, packets will be mandatorily defragmented.

It is possible to use either Multicast or Unicast to sync conntrack traffic. Most examples below show Multicast, but unicast can be specified by using the „peer“ keyword after the specified interface, as in the following example:

```
set service conntrack-sync interface eth0 peer 192.168.0.250
```

## Configuration

### **set service conntrack-sync accept-protocol**

Accept only certain protocols: You may want to replicate the state of flows depending on their layer 4 protocol.

Protocols are: tcp, sctp, dccp, udp, icmp and ipv6-icmp.

### **set service conntrack-sync event-listen-queue-size <size>**

The daemon doubles the size of the netlink event socket buffer size if it detects netlink event message dropping. This clause sets the maximum buffer size growth that can be reached.

Queue size for listening to local conntrack events in MB.

### **set service conntrack-sync expect-sync <all|ftp|h323|nfs|sip|sqlnet>**

Protocol for which expect entries need to be synchronized.

### **set service conntrack-sync failover-mechanism vrrp sync-group <group>**

Failover mechanism to use for conntrack-sync.

Only VRRP is supported. Required option.

### **set service conntrack-sync ignore-address <x.x.x.x>**

IP addresses or networks for which local conntrack entries will not be synced

### **set service conntrack-sync interface <name>**

Interface to use for syncing conntrack entries.

### **set service conntrack-sync interface <name> port <port>**

Port number used by connection.

### **set service conntrack-sync listen-address <ipv4address>**

Local IPv4 addresses for service to listen on.

### **set service conntrack-sync mcast-group <x.x.x.x>**

Multicast group to use for syncing conntrack entries.

Defaults to 225.0.0.50.

### **set service conntrack-sync interface <name> peer <address>**

Peer to send unicast UDP conntrack sync entries to, if not using Multicast configuration from above above.

### **set service conntrack-sync sync-queue-size <size>**

Queue size for syncing conntrack entries in MB.

### **set service conntrack-sync disable-external-cache**

This disable the external cache and directly injects the flow-states into the in-kernel Connection Tracking System of the backup firewall.

### **set service conntrack-sync disable-syslog**

Disable connection logging via Syslog.

### **set service conntrack-sync startup-resync**

Order conntrackd to request a complete conntrack table resync against the other node at startup.

## Operation

### show conntrack table ipv4

Make sure conntrack is enabled by running and show connection tracking table.

```
vyos@vyos:~$ show conntrack table ipv4
TCP state codes: SS - SYN SENT, SR - SYN RECEIVED, ES - ESTABLISHED,
                  FW - FIN WAIT, CW - CLOSE WAIT, LA - LAST ACK,
                  TW - TIME WAIT, CL - CLOSE, LI - LISTEN

CONN ID   Source           Destination           Protocol             TIMEOUT
1015736576 10.35.100.87:58172    172.31.20.12:22      tcp [6] ES          430279
1006235648 10.35.101.221:57483   172.31.120.21:22     tcp [6] ES          413310
1006237088 10.100.68.100         172.31.120.21        icmp [1]             29
1015734848 10.35.100.87:56282    172.31.20.12:22      tcp [6] ES          300
1015734272 172.31.20.12:60286    239.10.10.14:694     udp [17]             29
1006239392 10.35.101.221         172.31.120.21        icmp [1]             29
```

**Bemerkung:** If the table is empty and you have a warning message, it means conntrack is not enabled. To enable conntrack, just create a NAT or a firewall rule. `set firewall state-policy established action accept`

### show conntrack-sync cache external

Show connection syncing external cache entries

### show conntrack-sync cache internal

Show connection syncing internal cache entries

### show conntrack-sync statistics

Retrieve current statistics of connection tracking subsystem.

```
vyos@vyos:~$ show conntrack-sync statistics
Main Table Statistics:

cache internal:
current active connections:      19606
connections created:             6298470   failed:      0
connections updated:             3786793   failed:      0
connections destroyed:           6278864   failed:      0

cache external:
current active connections:      15771
connections created:             1660193   failed:      0
connections updated:             77204    failed:      0
connections destroyed:           1644422   failed:      0

traffic processed:
                                0 Bytes                0 Pkts

multicast traffic (active device=eth0.5):
          976826240 Bytes sent          212898000 Bytes recv
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

8302333 Pkts sent      2009929 Pkts rcv
  0 Error send         0 Error rcv

message tracking:
  0 Malformed msgs      263 Lost msgs
    
```

### show conntrack-sync status

Retrieve current status of connection tracking subsystem.

```

vyos@vyos:~$ show conntrack-sync status
sync-interface       : eth0.5
failover-mechanism   : vrrp [sync-group GEFOEKOM]
last state transition : no transition yet!
ExpectationSync      : disabled
    
```

### Example

The next example is a simple configuration of conntrack-sync.

Now configure conntrack-sync service on **router1** and **router2**

```

set high-availability vrrp group internal virtual-address ... etc ...
set high-availability vrrp sync-group syncgrp member 'internal'
set service conntrack-sync accept-protocol 'tcp'
set service conntrack-sync accept-protocol 'udp'
    
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set service conntrack-sync accept-protocol 'icmp'
set service conntrack-sync failover-mechanism vrrp sync-group 'syncgrp'
set service conntrack-sync interface 'eth0'
set service conntrack-sync mcast-group '225.0.0.50'

```

On the active router, you should have information in the internal-cache of conntrack-sync. The same current active connections number should be shown in the external-cache of the standby router

On active router run:

```
$ show conntrack-sync statistics
```

Main Table Statistics:

cache internal:

current active connections:	10		
connections created:	8517	failed:	0
connections updated:	127	failed:	0
connections destroyed:	8507	failed:	0

cache external:

current active connections:	0		
connections created:	0	failed:	0
connections updated:	0	failed:	0
connections destroyed:	0	failed:	0

traffic processed:

0 Bytes	0 Pkts
---------	--------

multicast traffic (active device=eth0):

868780 Bytes sent	224136 Bytes recv
20595 Pkts sent	14034 Pkts recv
0 Error send	0 Error recv

message tracking:

0 Malformed msgs	0 Lost msgs
------------------	-------------

On standby router run:

```
$ show conntrack-sync statistics
```

Main Table Statistics:

cache internal:

current active connections:	0		
connections created:	0	failed:	0
connections updated:	0	failed:	0
connections destroyed:	0	failed:	0

cache external:

current active connections:	10		
connections created:	888	failed:	0
connections updated:	134	failed:	0

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

connections destroyed:	878	failed:	0
traffic processed:	0 Bytes	0 Pkts	
multicast traffic (active device=eth0):			
234184 Bytes sent		907504 Bytes recv	
14663 Pkts sent		21495 Pkts recv	
0 Error send		0 Error recv	
message tracking:			
0 Malformed msgs		0 Lost msgs	

## 8.10.4 Console Server

Starting of with VyOS 1.3 (equuleus) we added support for running VyOS as an Out-of-Band Management device which provides remote access by means of SSH to directly attached serial interfaces.

Serial interfaces can be any interface which is directly connected to the CPU or chipset (mostly known as a ttyS interface in Linux) or any other USB to serial converter (Prolific PL2303 or FTDI FT232/FT4232 based chips).

If you happened to use a Cisco NM-16A - Sixteen Port Async Network Module or NM-32A - Thirty-two Port Async Network Module - this is your VyOS replacement.

For USB port information please refer to: [USB](#).

### Configuration

Between computers, the most common configuration used was „8N1“: eight bit characters, with one start bit, one stop bit, and no parity bit. Thus 10 Baud times are used to send a single character, and so dividing the signalling bit-rate by ten results in the overall transmission speed in characters per second. This is also the default setting if none of those options are defined.

**set service console-server device <device> data-bits [7 | 8]**

Configure either seven or eight data bits. This defaults to eight data bits if left unconfigured.

**set service console-server device <device> description <string>**

A user friendly description identifying the connected peripheral.

**set service console-server device <device> alias <string>**

A user friendly alias for this connection. Can be used instead of the device name when connecting.

**set service console-server device <device> parity [even | odd | none]**

Set the parity option for the console. If unset this will default to none.

**set service console-server device <device> stop-bits [1 | 2]**

Configure either one or two stop bits. This defaults to one stop bits if left unconfigured.

**set service console-server device <device> speed [ 300 | 1200 | 2400 | 4800 | 9600 | 19200 | 38400 | 57600 | 115200 ]**

---

**Bemerkung:** USB to serial converters will handle most of their work in software so you should be careful with the selected baudrate as some times they can't cope with the expected speed.

---

## Remote Access

Each individual configured console-server device can be directly exposed to the outside world. A user can directly connect via SSH to the configured port.

**set service console-server device <device> ssh port <port>**

Accept SSH connections for the given <device> on TCP port <port>. After successful authentication the user will be directly dropped to the connected serial device.

---

**Hinweis:** Multiple users can connect to the same serial device but only one is allowed to write to the console port.

---

## Operation

**show console-server ports**

Show configured serial ports and their respective interface configuration.

```
vyos@vyos:~$ show console-server ports
usb0b2.4p1.0          on /dev/serial/by-bus/usb0b2.4p1.0@ at 9600n
```

**show console-server user**

Show currently connected users.

```
vyos@vyos:~$ show console-server user
usb0b2.4p1.0          up   vyos@localhost
```

**connect console <device>**

Locally connect to serial port identified by <device>.

```
vyos@vyos-r1:~$ connect console usb0b2.4p1.0
[Enter ^Ec? for help]
[-- MOTD -- VyOS Console Server]

vyos-r2 login:
```

---

**Hinweis:** Multiple users can connect to the same serial device but only one is allowed to write to the console port.

---

---

**Hinweis:** The sequence ^Ec? translates to: Ctrl+E c ?. To quit the session use: Ctrl+E c .

---

---

**Hinweis:** If `alias` is set, it can be used instead of the device when connecting.

---

### **show log console-server**

Show the console server log.

## **8.10.5 DHCP Relay**

If you want your router to forward DHCP requests to an external DHCP server you can configure the system to act as a DHCP relay agent. The DHCP relay agent works with IPv4 and IPv6 addresses.

All interfaces used for the DHCP relay must be configured. This includes the uplink to the DHCP server.

### **IPv4 relay**

#### **Configuration**

##### **set service dhcp-relay interface <interface>**

Interfaces that participate in the DHCP relay process. If this command is used, at least two entries of it are required: one for the interface that captures the dhcp-requests, and one for the interface to forward such requests. A warning message will be shown if this command is used, since new implementations should use `listen-interface` and `upstream-interface`.

##### **set service dhcp-relay listen-interface <interface>**

Interface for DHCP Relay Agent to listen for requests.

##### **set service dhcp-relay upstream-interface <interface>**

Interface for DHCP Relay Agent to forward requests out.

##### **set service dhcp-relay server <server>**

Configure IP address of the DHCP <server> which will handle the relayed packets.

##### **set service dhcp-relay relay-options relay-agents-packets discard**

The router should discard DHCP packages already containing relay agent information to ensure that only requests from DHCP clients are forwarded.

##### **set service dhcp-relay disable**

Disable dhcp-relay service.

### **Options**

##### **set service dhcp-relay relay-options hop-count <count>**

Set the maximum hop <count> before packets are discarded. Range 0...255, default 10.

##### **set service dhcp-relay relay-options max-size <size>**

Set maximum <size> of DHCP packets including relay agent information. If a DHCP packet size surpasses this value it will be forwarded without appending relay agent information. Range 64...1400, default 576.

##### **set service dhcp-relay relay-options relay-agents-packets <append | discard | forward | replace>**

Four policies for reforwarding DHCP packets exist:

- **append:** The relay agent is allowed to append its own relay information to a received DHCP packet, disregarding relay information already present in the packet.
- **discard:** Received packets which already contain relay information will be discarded.
- **forward:** All packets are forwarded, relay information already present will be ignored.
- **replace:** Relay information already present in a packet is stripped and replaced with the router's own relay information set.

### Example

- Listen for DHCP requests on interface **eth1**.
- DHCP server is located at IPv4 address 10.0.1.4 on **eth2**.
- Router receives DHCP client requests on **eth1** and relays them to the server at 10.0.1.4 on **eth2**.

Abb. 3: DHCP relay example

The generated configuration will look like:

```
show service dhcp-relay
listen-interface eth1
upstream-interface eth2
server 10.0.1.4
relay-options {
    relay-agents-packets discard
}
```

Also, for backwards compatibility this configuration, which uses generic interface definition, is still valid:

```
show service dhcp-relay
interface eth1
interface eth2
server 10.0.1.4
relay-options {
    relay-agents-packets discard
}
```

## Operation

### **restart dhcp relay-agent**

Restart DHCP relay service

## IPv6 relay

## Configuration

### **set service dhcpv6-relay listen-interface <interface>**

Set eth1 to be the listening interface for the DHCPv6 relay.

Multiple interfaces may be specified.

### **set service dhcpv6-relay upstream-interface <interface> address <server>**

Specifies an upstream network <interface> from which replies from <server> and other relay agents will be accepted.

### **set service dhcpv6-relay disable**

Disable dhcpv6-relay service.

## Options

### **set service dhcpv6-relay max-hop-count <count>**

Set maximum hop count before packets are discarded, default: 10

### **set service dhcpv6-relay use-interface-id-option**

If this is set the relay agent will insert the interface ID. This option is set automatically if more than one listening interfaces are in use.

## Example

- DHCPv6 requests are received by the router on *listening interface* eth1
- Requests are forwarded through eth2 as the *upstream interface*
- External DHCPv6 server is at 2001:db8::4

The generated configuration will look like:

```
commit
show service dhcpv6-relay
  listen-interface eth1 {
  }
  upstream-interface eth2 {
    address 2001:db8::4
  }
```

Abb. 4: DHCPv6 relay example

## Operation

### **restart dhcpv6 relay-agent**

Restart DHCPv6 relay agent immediately.

## 8.10.6 DHCP Server

VyOS uses Kea DHCP server for both IPv4 and IPv6 address assignment.

### IPv4 server

The network topology is declared by `shared-network-name` and the subnet declarations. The DHCP service can serve multiple shared networks, with each shared network having 1 or more subnets. Each subnet must be present on an interface. A range can be declared inside a subnet to define a pool of dynamic addresses. Multiple ranges can be defined and can contain holes. Static mappings can be set to assign „static“ addresses to clients based on their MAC address.

## Configuration

### **set service dhcp-server hostfile-update**

Create DNS record per client lease, by adding clients to `/etc/hosts` file. Entry will have format: `<shared-network-name>_<hostname>.<domain-name>`

### **set service dhcp-server shared-network-name <name> option domain-name <domain-name>**

The `domain-name` parameter should be the domain name that will be appended to the client's hostname to form a fully-qualified domain-name (FQDN) (DHCP Option 015).

This is the configuration parameter for the entire shared network definition. All subnets will inherit this configuration item if not specified locally.

### **set service dhcp-server shared-network-name <name> option domain-search <domain-name>**

The `domain-name` parameter should be the domain name used when completing DNS request where no full FQDN is passed. This option can be given multiple times if you need multiple search domains (DHCP Option 119).

This is the configuration parameter for the entire shared network definition. All subnets will inherit this configuration item if not specified locally.

```
set service dhcp-server shared-network-name <name> option name-server <address>
```

Inform client that the DNS server can be found at *<address>*.

This is the configuration parameter for the entire shared network definition. All subnets will inherit this configuration item if not specified locally. Multiple DNS servers can be defined.

```
set service dhcp-server shared-network-name <name> option vendor-option <option-name>
```

This configuration parameter lets you specify a vendor-option for the entire shared network definition. All subnets will inherit this configuration item if not specified locally. An example for Ubiquiti is shown below:

#### Example:

Pass address of Unifi controller at 172.16.100.1 to all clients of NET1

```
set service dhcp-server shared-network-name 'NET1' option vendor-option
ubiquiti '172.16.100.1'
```

```
set service dhcp-server listen-address <address>
```

This configuration parameter lets the DHCP server to listen for DHCP requests sent to the specified address, it is only realistically useful for a server whose only clients are reached via unicasts, such as via DHCP relay agents.

### Individual Client Subnet

```
set service dhcp-server shared-network-name <name> authoritative
```

This says that this device is the only DHCP server for this network. If other devices are trying to offer DHCP leases, this machine will send ,DHCPNAK' to any device trying to request an IP address that is not valid for this network.

```
set service dhcp-server shared-network-name <name> subnet <subnet> subnet-id <id>
```

This configuration parameter is required and must be unique to each subnet. It is required to map subnets to lease file entries.

```
set service dhcp-server shared-network-name <name> subnet <subnet> option default-router <address>
```

This is a configuration parameter for the *<subnet>*, saying that as part of the response, tell the client that the default gateway can be reached at *<address>*.

```
set service dhcp-server shared-network-name <name> subnet <subnet> option name-server <address>
```

This is a configuration parameter for the subnet, saying that as part of the response, tell the client that the DNS server can be found at *<address>*.

Multiple DNS servers can be defined.

```
set service dhcp-server shared-network-name <name> subnet <subnet> lease <time>
```

Assign the IP address to this machine for *<time>* seconds.

The default value is 86400 seconds which corresponds to one day.

```
set service dhcp-server shared-network-name <name> subnet <subnet> range <n> start <address>
```

Create DHCP address range with a range id of *<n>*. DHCP leases are taken from this pool. The pool starts at address *<address>*.

```
set service dhcp-server shared-network-name <name> subnet <subnet> range <n> stop <address>
```

Create DHCP address range with a range id of *<n>*. DHCP leases are taken from this pool. The pool stops with address *<address>*.

```
set service dhcp-server shared-network-name <name> subnet <subnet> exclude <address>
```

Always exclude this address from any defined range. This address will never be assigned by the DHCP server.

This option can be specified multiple times.

```
set service dhcp-server shared-network-name <name> subnet <subnet> option domain-name <domain-name>
```

The domain-name parameter should be the domain name that will be appended to the client's hostname to form a fully-qualified domain-name (FQDN) (DHCP Option 015).

```
set service dhcp-server shared-network-name <name> subnet <subnet> option domain-search <domain-name>
```

The domain-name parameter should be the domain name used when completing DNS request where no full FQDN is passed. This option can be given multiple times if you need multiple search domains (DHCP Option 119).

```
set service dhcp-server shared-network-name <name> subnet <subnet> option vendor-option <option-name>
```

This configuration parameter lets you specify a vendor-option for the subnet specified within the shared network definition. An example for Ubiquiti is shown below:

#### Example:

Create 172.18.201.0/24 as a subnet within NET1 and pass address of Unifi controller at 172.16.100.1 to clients of that subnet.

```
set service dhcp-server shared-network-name 'NET1' subnet
'172.18.201.0/24' option vendor-option ubiquiti '172.16.100.1'
```

## High Availability

VyOS provides High Availability support for DHCP server. DHCP High Availability can act in two different modes:

- **Active-active:** both DHCP servers will respond to DHCP requests. If mode is not defined, this is the default behavior.
- **Active-passive:** only primary server will respond to DHCP requests. If this server goes offline, then secondary server will take place.

DHCP High Availability must be configured explicitly by the following statements on both servers:

```
set service dhcp-server high-availability mode [active-active | active-passive]
```

Define operation mode of High Availability feature. Default value if command is not specified is *active-active*

```
set service dhcp-server high-availability source-address <address>
```

Local IP *<address>* used when communicating to the HA peer.

```
set service dhcp-server high-availability remote <address>
```

Remote peer IP *<address>* of the second DHCP server in this HA cluster.

```
set service dhcp-server high-availability name <name>
```

A generic *<name>* referencing this sync service.

---

**Bemerkung:** *<name>* must be identical on both sides!

---

```
set service dhcp-server high-availability status <primary | secondary>
```

The primary and secondary statements determines whether the server is primary or secondary.

---

**Bemerkung:** In order for the primary and the secondary DHCP server to keep their lease tables in sync, they must be able to reach each other on TCP port 647. If you have firewall rules in effect, adjust them accordingly.

---

---

**Hinweis:** The dialogue between HA partners is neither encrypted nor authenticated. Since most DHCP servers exist within an organisation's own secure Intranet, this would be an unnecessary overhead. However, if you have DHCP HA peers whose communications traverse insecure networks, then we recommend that you consider the use of VPN tunneling between them to ensure that the HA partnership is immune to disruption (accidental or otherwise) via third parties.

---

## Static mappings

You can specify a static DHCP assignment on a per host basis. You will need the MAC address of the station and your desired IP address. The address must be inside the subnet definition but can be outside of the range statement.

```
set service dhcp-server shared-network-name <name> subnet <subnet> static-mapping
<description> mac <address>
```

Create a new DHCP static mapping named *<description>* which is valid for the host identified by its MAC *<address>*.

```
set service dhcp-server shared-network-name <name> subnet <subnet> static-mapping
<description> duid <identifier>
```

Create a new DHCP static mapping named *<description>* which is valid for the host identified by its DHCP unique identifier (DUID) *<identifier>*.

```
set service dhcp-server shared-network-name <name> subnet <subnet> static-mapping
<description> ip-address <address>
```

Static DHCP IP address assign to host identified by *<description>*. IP address must be inside the *<subnet>* which is defined but can be outside the dynamic range created with `set service dhcp-server shared-network-name <name> subnet <subnet> range <n>`. If no ip-address is specified, an IP from the dynamic pool is used.

This is useful, for example, in combination with hostfile update.

---

**Hinweis:** This is the equivalent of the host block in dhcpd.conf of isc-dhcpd.

---

### Example:

- IP address 192.168.1.100 shall be statically mapped to client named `client1`

```
set service dhcp-server shared-network-name 'NET1' subnet 192.168.1.0/24 subnet-id 1
set service dhcp-server shared-network-name 'NET1' subnet 192.168.1.0/24 static-mapping_
↪client1 ip-address 192.168.1.100
set service dhcp-server shared-network-name 'NET1' subnet 192.168.1.0/24 static-mapping_
↪client1 mac aa:bb:11:22:33:00
```

The configuration will look as follows:

```
show service dhcp-server shared-network-name NET1
  subnet 192.168.1.0/24 {
    static-mapping client1 {
      ip-address 192.168.1.100
      mac aa:bb:11:22:33:00
    }
    subnet-id 1
  }
```

## Options

Setting name	Option number	ISC-DHCP name	Option	Option description	Multi
client-prefix-length	1	subnet-mask		Specifies the clients subnet mask as per RFC 950. If unset, subnet declaration is used.	N
time-offset	2	time-offset		Offset of the client's subnet in seconds from Coordinated Universal Time (UTC)	N
default-router	3	routers		IPv4 address of router on the client's subnet	N
time-server	4	time-servers		RFC 868 time server IPv4 address	Y
name-server	6	domain-name-servers		DNS server IPv4 address	Y
domain-name	15	domain-name		Client domain name	Y
ip-forwarding	19	ip-forwarding		Enable IP forwarding on client	N
ntp-server	42	ntp-servers		IP address of NTP server	Y
wins-server	44	netbios-name-servers		NetBIOS over TCP/IP name server	Y
server-identifier	54	dhcp-server-identifier		IP address for DHCP server identifier	N
bootfile-server	siad-dr	next-server		IPv4 address of next bootstrap server	N
tftp-server-name	66	tftp-server-name		Name or IPv4 address of TFTP server	N
bootfile-name	67	bootfile-name, filename		Bootstrap file name	N
bootfile-size	13	boot-size		Boot image length in 512-octet blocks	N
smtp-server	69	smtp-server		IP address of SMTP server	Y
pop-server	70	pop-server		IP address of POP3 server	Y
domain-search	119	domain-search		Client domain search	Y
static-route	121, 249	rfc3442-static-route, windows-static-route		Classless static route	N
wpad-url	252	wpad-url, wpad-url code 252 = text		Web Proxy Autodiscovery (WPAD) URL	N
lease		default-lease-time, max-lease-time		Lease timeout in seconds (default: 86400)	N
range		range		DHCP lease range	Y
exclude				IP address to exclude from DHCP lease range	Y
failover				DHCP failover parameters	
static-mapping				Name of static mapping	Y

Multi: can be specified multiple times.

## Example

Please see the *DHCP/DNS quick-start* configuration.

## High Availability

Configuration of a DHCP HA pair:

- Setup DHCP HA for network 192.0.2.0/24
- Use active-active HA mode.
- Default gateway and DNS server is at 192.0.2.254
- The primary DHCP server uses address 192.168.189.252
- The secondary DHCP server uses address 192.168.189.253
- DHCP range spans from 192.168.189.10 - 192.168.189.250

Common configuration, valid for both primary and secondary node.

```
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 option default-
↪router '192.0.2.254'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 option name-
↪server '192.0.2.254'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 option domain-
↪name 'vyos.net'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 range 0 start
↪'192.0.2.10'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 range 0 stop
↪'192.0.2.250'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 subnet-id '1'
```

### Primary

```
set service dhcp-server high-availability mode 'active-active'
set service dhcp-server high-availability source-address '192.168.189.252'
set service dhcp-server high-availability name 'NET-VYOS'
set service dhcp-server high-availability remote '192.168.189.253'
set service dhcp-server high-availability status 'primary'
```

### Secondary

```
set service dhcp-server high-availability mode 'active-active'
set service dhcp-server high-availability source-address '192.168.189.253'
set service dhcp-server high-availability name 'NET-VYOS'
set service dhcp-server high-availability remote '192.168.189.252'
set service dhcp-server high-availability status 'secondary'
```

## Operation Mode

### show log dhcp server

Show DHCP server daemon log file

### show log dhcp client

Show logs from all DHCP client processes.

### show log dhcp client interface <interface>

Show logs from specific *interface* DHCP client process.

### restart dhcp server

Restart the DHCP server

### show dhcp server statistics

Show the DHCP server statistics:

```
vyos@vyos:~$ show dhcp server statistics
Pool          Size    Leases    Available    Usage
-----
dhcpexample    99        2          97         2%
```

### show dhcp server statistics pool <pool>

Show the DHCP server statistics for the specified pool.

### show dhcp server leases

Show statuses of all active leases:

```
vyos@vyos:~$ show dhcp server leases
IP Address      MAC address      State    Lease start      Lease expiration
↳ Remaining    Pool            Hostname    Origin
-----
↳
192.168.11.134  00:50:79:66:68:09 active    2023/11/29 09:51:05 2023/11/29 10:21:05 ↳
↳ 0:24:10      LAN            VPCS1      local
192.168.11.133  50:00:00:06:00:00 active    2023/11/29 09:51:38 2023/11/29 10:21:38 ↳
↳ 0:24:43      LAN            VYOS-6     local
10.11.11.108    50:00:00:05:00:00 active    2023/11/29 09:51:43 2023/11/29 10:21:43 ↳
↳ 0:24:48      VIF-1001      VYOS5      local
192.168.11.135  00:50:79:66:68:07 active    2023/11/29 09:55:16 2023/11/29 09:59:16 ↳
↳ 0:02:21                      remote
vyos@vyos:~$
```

---

**Hinweis:** Static mappings aren't shown. To show all states, use `show dhcp server leases state all`.

---

### show dhcp server leases origin [local | remote]

Show statuses of all active leases granted by local (this server) or remote (failover server):

```
vyos@vyos:~$ show dhcp server leases origin remote
IP Address      MAC address      State    Lease start      Lease expiration
(Fortsetzung auf der nächsten Seite)
```

(Fortsetzung der vorherigen Seite)

↪ Remaining	Pool	Hostname	Origin		
↪ -----	-----	-----	-----	-----	-----
192.168.11.135	00:50:79:66:68:07	active	2023/11/29 09:55:16	2023/11/29 09:59:16	↪
↪ 0:02:21		remote			
vyos@vyos:~\$					

### show dhcp server leases pool <pool>

Show only leases in the specified pool.

```
vyos@vyos:~$ show dhcp server leases pool LAN
```

IP Address	MAC address	State	Lease start	Lease expiration	↪
↪ Remaining	Pool	Hostname	Origin		
↪ -----	-----	-----	-----	-----	-----
192.168.11.134	00:50:79:66:68:09	active	2023/11/29 09:51:05	2023/11/29 10:21:05	↪
↪ 0:23:55	LAN	VPCS1	local		
192.168.11.133	50:00:00:06:00:00	active	2023/11/29 09:51:38	2023/11/29 10:21:38	↪
↪ 0:24:28	LAN	VYOS-6	local		
vyos@vyos:~\$					

### show dhcp server leases sort <key>

Sort the output by the specified key. Possible keys: ip, hardware\_address, state, start, end, remaining, pool, hostname (default = ip)

### show dhcp server leases state <state>

Show only leases with the specified state. Possible states: all, active, free, expired, released, abandoned, reset, backup (default = active)

## IPv6 server

VyOS also provides DHCPv6 server functionality which is described in this section.

## Configuration

### set service dhcpv6-server preference <preference value>

Clients receiving advertise messages from multiple servers choose the server with the highest preference value. The range for this value is 0...255.

### set service dhcpv6-server shared-network-name <name> subnet <subnet> subnet-id <id>

This configuration parameter is required and must be unique to each subnet. It is required to map subnets to lease file entries.

### set service dhcpv6-server shared-network-name <name> subnet <prefix> lease-time {default | maximum | minimum}

The default lease time for DHCPv6 leases is 24 hours. This can be changed by supplying a default-time, maximum-time and minimum-time. All values need to be supplied in seconds.

### set service dhcpv6-server shared-network-name <name> subnet <prefix> option nis-domain <domain-name>

A NIS (Network Information Service) domain can be set to be used for DHCPv6 clients.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix> option
nisplus-domain <domain-name>
```

The procedure to specify a NIS+ (Network Information Service Plus) domain is similar to the NIS domain one:

```
set service dhcpv6-server shared-network-name <name> subnet <prefix> option nis-server
<address>
```

Specify a NIS server address for DHCPv6 clients.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix> option
nisplus-server <address>
```

Specify a NIS+ server address for DHCPv6 clients.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix> option sip-server
<address | fqdn>
```

Specify a SIP (Session Initiation Protocol) server by IPv6 address of Fully Qualified Domain Name for all DHCPv6 clients.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix> option
sntp-server-address <address>
```

A SNTP server address can be specified for DHCPv6 clients.

## Prefix Delegation

To hand out individual prefixes to your clients the following configuration is used:

```
set service dhcpv6-server shared-network-name <name> subnet <prefix> prefix-delegation
start <address> prefix-length <length>
```

Hand out prefixes of size *<length>* to clients in subnet *<prefix>* when they request for prefix delegation.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix> prefix-delegation
start <address> stop <address>
```

Delegate prefixes from the range indicated by the start and stop qualifier.

## Address pools

DHCPv6 address pools must be configured for the system to act as a DHCPv6 server. The following example describes a common scenario.

### Example:

- A shared network named NET1 serves subnet 2001:db8::/64
- It is connected to eth1
- DNS server is located at 2001:db8::ffff
- Address pool shall be 2001:db8::100 through 2001:db8::199.
- Lease time will be left at the default value which is 24 hours

```

set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 range 1 start_
↪2001:db8::100 stop 2001:db8::199
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 range 1 stop_
↪2001:db8::199
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 option name-
↪server 2001:db8::ffff
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 subnet-id 1

```

The configuration will look as follows:

```

show service dhcpv6-server
  shared-network-name NET1 {
    subnet 2001:db8::/64 {
      range 1 {
        start 2001:db8::100
        stop 2001:db8::199
      }
      option {
        name-server 2001:db8::ffff
      }
      subnet-id 1
    }
  }

```

## Static mappings

In order to map specific IPv6 addresses to specific hosts static mappings can be created. The following example explains the process.

### Example:

- IPv6 address 2001:db8::101 shall be statically mapped
- IPv6 prefix 2001:db8:0:101::/64 shall be statically mapped
- Host specific mapping shall be named `client1`

**Hinweis:** The identifier is the device's DUID: colon-separated hex list (as used by `isc-dhcp` option `dhcpv6.client-id`). If the device already has a dynamic lease from the DHCPv6 server, its DUID can be found with `show service dhcpv6 server leases`. The DUID begins at the 5th octet (after the 4th colon) of `IAID_DUID`.

```

set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 static-mapping_
↪client1 ipv6-address 2001:db8::101
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 static-mapping_
↪client1 ipv6-prefix 2001:db8:0:101::/64
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 static-mapping_
↪client1 duid 00:01:00:01:12:34:56:78:aa:bb:cc:dd:ee:ff

```

The configuration will look as follows:

```

show service dhcpv6-server shared-network-name NET1
  subnet 2001:db8::/64 {

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
static-mapping client1 {
    duid 00:01:00:01:12:34:56:78:aa:bb:cc:dd:ee:ff
    ipv6-address 2001:db8::101
    ipv6-prefix 2001:db8:0:101::/64
}
```

## Operation Mode

### show log dhcpv6 server

Show DHCPv6 server daemon log file

### show log dhcpv6 client

Show logs from all DHCPv6 client processes.

### show log dhcpv6 client interface <interface>

Show logs from specific *interface* DHCPv6 client process.

### restart dhcpv6 server

To restart the DHCPv6 server

### show dhcpv6 server leases

Shows status of all assigned leases:

```
vyos@vyos:~$ show dhcpv6 server leases
IPv6 address  State  Last communication  Lease expiration  Remaining  Type
↳ Pool  IAID_DUID
-----
↳ -----
2001:db8::101 active  2019/12/05 19:40:10  2019/12/06 07:40:10  11:45:21  non-
↳temporary NET1  98:76:54:32:00:01:00:01:12:34:56:78:aa:bb:cc:dd:ee:ff
2001:db8::102 active  2019/12/05 14:01:23  2019/12/06 02:01:23  6:06:34  non-

```

**Hinweis:** Static mappings aren't shown. To show all states, use `show dhcp server leases state all`.

### show dhcpv6 server leases pool <pool>

Show only leases in the specified pool.

### show dhcpv6 server leases sort <key>

Sort the output by the specified key. Possible keys: expires, iaid\_duid, ip, last\_comm, pool, remaining, state, type (default = ip)

### show dhcpv6 server leases state <state>

Show only leases with the specified state. Possible states: abandoned, active, all, backup, expired, free, released, reset (default = active)

## 8.10.7 DNS Forwarding

### Configuration

VyOS provides DNS infrastructure for small networks. It is designed to be lightweight and have a small footprint, suitable for resource constrained routers and firewalls. For this we utilize PowerDNS recursor.

The VyOS DNS forwarder does not require an upstream DNS server. It can serve as a full recursive DNS server - but it can also forward queries to configurable upstream DNS servers. By not configuring any upstream DNS servers you also avoid being tracked by the provider of your upstream DNS server.

#### **set service dns forwarding system**

Forward incoming DNS queries to the DNS servers configured under the `system name-server` nodes.

#### **set service dns forwarding dhcp <interface>**

Interfaces whose DHCP client nameservers to forward requests to.

#### **set service dns forwarding name-server <address> port <port>**

Send all DNS queries to the IPv4/IPv6 DNS server specified under `<address>` on optional port specified under `<port>`. The port defaults to 53. You can configure multiple nameservers here.

#### **set service dns forwarding domain <domain-name> name-server <address>**

Forward received queries for a particular domain (specified via `domain-name`) to a given nameserver. Multiple nameservers can be specified. You can use this feature for a DNS split-horizon configuration.

---

**Bemerkung:** This also works for reverse-lookup zones (`18.172.in-addr.arpa`).

---

#### **set service dns forwarding domain <domain-name> addnta**

Add NTA (negative trust anchor) for this domain. This must be set if the domain does not support DNSSEC.

#### **set service dns forwarding domain <domain-name> recursion-desired**

Set the „recursion desired“ bit in requests to the upstream nameserver.

#### **set service dns forwarding allow-from <network>**

Given the fact that open DNS recursors could be used on DDoS amplification attacks, you must configure the networks which are allowed to use this recursor. A network of `0.0.0.0/0` or `::/0` would allow all IPv4 and IPv6 networks to query this server. This is generally a bad idea.

#### **set service dns forwarding dnssec <off | process-no-validate | process | log-fail | validate>**

The PowerDNS recursor has 5 different levels of DNSSEC processing, which can be set with the `dnssec` setting. In order from least to most processing, these are:

- **off** In this mode, no DNSSEC processing takes place. The recursor will not set the DNSSEC OK (DO) bit in the outgoing queries and will ignore the DO and AD bits in queries.
- **process-no-validate** In this mode the recursor acts as a „security aware, non-validating“ nameserver, meaning it will set the DO-bit on outgoing queries and will provide DNSSEC related RRsets (NSEC, RRSIG) to clients that ask for them (by means of a DO-bit in the query), except for zones provided through the `auth-zones` setting. It will not do any validation in this mode, not even when requested by the client.
- **process** When `dnssec` is set to `process` the behavior is similar to `process-no-validate`. However, the recursor will try to validate the data if at least one of the DO or AD bits is set in the query; in that case, it will set

the AD-bit in the response when the data is validated successfully, or send SERVFAIL when the validation comes up bogus.

- **log-fail** In this mode, the recursor will attempt to validate all data it retrieves from authoritative servers, regardless of the client's DNSSEC desires, and will log the validation result. This mode can be used to determine the extra load and amount of possibly bogus answers before turning on full-blown validation. Responses to client queries are the same as with process.
- **validate** The highest mode of DNSSEC processing. In this mode, all queries will be validated and will be answered with a SERVFAIL in case of bogus data, regardless of the client's request.

---

**Bemerkung:** The popular Unix/Linux `dig` tool sets the AD-bit in the query. This might lead to unexpected query results when testing. Set `+noad` on the `dig` command line when this is the case.

---

---

**Bemerkung:** The CD-bit is honored correctly for process and validate. For log-fail, failures will be logged too.

---

### **set service dns forwarding ignore-hosts-file**

Do not use the local `/etc/hosts` file in name resolution. VyOS DHCP server will use this file to add resolvers to assigned addresses.

### **set service dns forwarding cache-size <0-2147483647>**

Maximum number of DNS cache entries. 1 million per CPU core will generally suffice for most installations.

This defaults to 10000.

### **set service dns forwarding negative-ttl <0-7200>**

A query for which there is authoritatively no answer is cached to quickly deny a record's existence later on, without putting a heavy load on the remote server. In practice, caches can become saturated with hundreds of thousands of hosts which are tried only once.

This setting, which defaults to 3600 seconds, puts a maximum on the amount of time negative entries are cached.

### **set service dns forwarding timeout <10-60000>**

The number of milliseconds to wait for a remote authoritative server to respond before timing out and responding with SERVFAIL.

This setting defaults to 1500 and is valid between 10 and 60000.

### **set service dns forwarding listen-address <address>**

The local IPv4 or IPv6 addresses to bind the DNS forwarder to. The forwarder will listen on this address for incoming connections.

### **set service dns forwarding source-address <address>**

The local IPv4 or IPv6 addresses to use as a source address for sending queries. The forwarder will send forwarded outbound DNS requests from this address.

### **set service dns forwarding no-serve-rfc1918**

This makes the server authoritatively not aware of: 10.in-addr.arpa, 168.192.in-addr.arpa, 16-31.172.in-addr.arpa, which enabling upstream DNS server(s) to be used for reverse lookups of these zones.

## Authoritative zones

The VyOS DNS forwarder can also be configured to host authoritative records for a domain.

```
set service dns forwarding authoritative-domain <domain-name> disable
```

Disable hosting authoritative zone for *<domain-name>* without deleting from configuration.

```
set service dns forwarding authoritative-domain <domain-name> records <type> <name> disable
```

Disable specific record without deleting it from configuration.

```
set service dns forwarding authoritative-domain <domain-name> records <type> <name> ttl <seconds>
```

Set the TTL (Time-to-live) for the record in seconds. Default is 300 seconds.

## Record types

Below are a list of record types available to be configured within VyOS. Some records support special *<name>* keywords:

- **@** Use @ as record name to set the record for the root domain.
- **any** Use any as record name to configure the record as a wildcard.

```
set service dns forwarding authoritative-domain <domain-name> records a <name> address <x.x.x.x>
```

Set an A (Address) record. Supports @ and any keywords.

```
set service dns forwarding authoritative-domain <domain-name> records aaaa <name> address <h:h:h:h:h:h:h:h>
```

Set an AAAA (IPv6 Address) record. Supports @ and any keywords.

```
set service dns forwarding authoritative-domain <domain-name> records cname <name> target <target-domain-name>
```

Set an CNAME (Canonical name) record. Supports @ keyword.

```
set service dns forwarding authoritative-domain <domain-name> records naptr <name> rule <rule-number> <option> <value>
```

Set an NAPTR (Naming authority pointer) record. Supports @ keyword. NAPTR records support the following options:

- **lookup-a** A Flag.
- **lookup-srv** S flag.
- **order** Rule order. Requires *<value>*.
- **preference** Rule preference. Requires *<value>*. Defaults to 0 if not set.
- **protocol-specific** P flag.
- **regexp** Regular expression. Requires *<value>*.
- **replacement** Replacement DNS name.
- **resolve-uri** U flag.
- **service** Service type. Requires *<value>*.

```
set service dns forwarding authoritative-domain <domain-name> records ns <name> target
<target-name>
```

Set an NS (Nameserver) record.

```
set service dns forwarding authoritative-domain <domain-name> records ptr <name> target
<target-name>
```

Set an PTR (Pointer record) record. Supports @ keyword.

```
set service dns forwarding authoritative-domain <domain-name> records spf <name> value
<value>
```

Set an SPF (Sender policy framework) record. Supports @ keyword.

```
set service dns forwarding authoritative-domain <domain-name> records srv <name> entry
<entry-number> [hostname | port | priority | weight] <value>
```

Set an SRV (Service) record. Supports @ keyword.

```
set service dns forwarding authoritative-domain <domain-name> records txt <name> value
<value>
```

Set an TXT (Text) record. Supports @ keyword.

## Example

A VyOS router with two interfaces - eth0 (WAN) and eth1 (LAN) - is required to implement a split-horizon DNS configuration for example.com.

In this scenario:

- All DNS requests for example.com must be forwarded to a DNS server at 192.0.2.254 and 2001:db8:cafe::1
- All other DNS requests will be forwarded to a different set of DNS servers at 192.0.2.1, 192.0.2.2, 2001:db8::1:ffff and 2001:db8::2:ffff
- The VyOS DNS forwarder will only listen for requests on the eth1 (LAN) interface addresses - 192.168.1.254 for IPv4 and 2001:db8::ffff for IPv6
- The VyOS DNS forwarder will only accept lookup requests from the LAN subnets - 192.168.1.0/24 and 2001:db8::/64
- The VyOS DNS forwarder will pass reverse lookups for 10.in-addr.arpa, 168.192.in-addr.arpa, 16-31.172.in-addr.arpa zones to upstream server.

```
set service dns forwarding domain example.com name-server 192.0.2.254
set service dns forwarding domain example.com name-server 2001:db8:cafe::1
set service dns forwarding name-server 192.0.2.1
set service dns forwarding name-server 192.0.2.2
set service dns forwarding name-server 192.0.2.3 port 853
set service dns forwarding name-server 2001:db8::1:ffff
set service dns forwarding name-server 2001:db8::2:ffff
set service dns forwarding name-server 2001:db8::3:ffff port 8053
set service dns forwarding listen-address 192.168.1.254
set service dns forwarding listen-address 2001:db8::ffff
set service dns forwarding allow-from 192.168.1.0/24
set service dns forwarding allow-from 2001:db8::/64
set service dns forwarding no-serve-rfc1918
```

## Operation

### **reset dns forwarding <all | domain>**

Resets the local DNS forwarding cache database. You can reset the cache for all entries or only for entries to a specific domain.

### **restart dns forwarding**

Restarts the DNS recursor process. This also invalidates the local DNS forwarding cache.

## 8.10.8 Dynamic DNS

VyOS is able to update a remote DNS record when an interface gets a new IP address. In order to do so, VyOS includes `ddclient`, a Perl script written for this only one purpose.

`ddclient` uses two methods to update a DNS record. The first one will send updates directly to the DNS daemon, in compliance with [RFC 2136](#). The second one involves a third party service, like DynDNS.com or any other such service provider. This method uses HTTP requests to transmit the new IP address. You can configure both in VyOS.

## Configuration

### RFC 2136 Based

#### **set service dns dynamic name <service-name> address interface <interface>**

Create new dynamic DNS update configuration which will update the IP address assigned to *<interface>* on the service you configured under *<service-name>*.

#### **set service dns dynamic name <service-name> description <text>**

Set description *<text>* for dynamic DNS service being configured.

#### **set service dns dynamic name <service-name> key <filename>**

File identified by *<filename>* containing the TSIG authentication key for RFC2136 nsupdate on remote DNS server.

#### **set service dns dynamic name <service-name> server <server>**

Configure the DNS *<server>* IP/FQDN used when updating this dynamic assignment.

#### **set service dns dynamic name <service-name> zone <zone>**

Configure DNS *<zone>* to be updated.

#### **set service dns dynamic name <service-name> host-name <record>**

Configure DNS *<record>* which should be updated. This can be set multiple times.

#### **set service dns dynamic name <service-name> ttl <ttl>**

Configure optional TTL value on the given resource record. This defaults to 600 seconds.

#### **set service dns dynamic interval <60-3600>**

Specify interval in seconds to wait between Dynamic DNS updates. The default is 300 seconds.

## Example

- Register DNS record `example.vyos.io` on DNS server `ns1.vyos.io`
- Use auth key file at `/config/auth/my.key`
- Set TTL to 300 seconds

```
# Configuration commands entered:
#
set service dns dynamic name 'VyOS-DNS' address interface 'eth0'
set service dns dynamic name 'VyOS-DNS' description 'RFC 2136 dynamic dns service'
set service dns dynamic name 'VyOS-DNS' key '/config/auth/my.key'
set service dns dynamic name 'VyOS-DNS' server 'ns1.vyos.io'
set service dns dynamic name 'VyOS-DNS' zone 'vyos.io'
set service dns dynamic name 'VyOS-DNS' host-name 'example.vyos.io'
set service dns dynamic name 'VyOS-DNS' protocol 'nsupdate'
set service dns dynamic name 'VyOS-DNS' ttl '300'

# Resulting config:
#
vyos@vyos# show service dns dynamic
name VyOS-DNS {
    address {
        interface eth0
    }
    description "RFC 2136 dynamic dns service"
    host-name example.vyos.io
    key /config/auth/my.key
    protocol nsupdate
    server ns1.vyos.io
    ttl 300
    zone vyos.io
}
```

This will render the following `ddclient` configuration entry:

```
# ddclient configuration for interface "eth0":
#

# Web service dynamic DNS configuration for VyOS-DNS: [nsupdate, example.vyos.io]
use=if, \
if=eth0, \
protocol=nsupdate, \
server=ns1.vyos.io, \
zone=vyos.io, \
password='/config/auth/my.key', \
ttl=300 \
example.vyos.io
```

---

**Bemerkung:** You can also keep different DNS zone updated. Just create a new config node: `set service dns dynamic interface <interface> rfc2136 <other-service-name>`

---

## HTTP based services

VyOS is also able to use any service relying on protocols supported by ddclient.

To use such a service, one must define a login, password, one or multiple hostnames, protocol and server.

**set service dns dynamic name <service-name> address interface <interface>**

Create new dynamic DNS update configuration which will update the IP address assigned to <interface> on the service you configured under <service-name>.

**set service dns dynamic name <service-name> description <text>**

Set description <text> for dynamic DNS service being configured.

**set service dns dynamic name <service-name> host-name <hostname>**

Setup the dynamic DNS hostname <hostname> associated with the DynDNS provider identified by <service-name>.

**set service dns dynamic name <service-name> username <username>**

Configure <username> used when authenticating the update request for DynDNS service identified by <service-name>.

**set service dns dynamic name <service-name> password <password>**

Configure <password> used when authenticating the update request for DynDNS service identified by <service-name>.

**set service dns dynamic name <service-name> protocol <protocol>**

When a custom DynDNS provider is used, the protocol used for communicating to the provider must be specified under <protocol>. See the embedded completion helper when entering above command for available protocols.

**set service dns dynamic name <service-name> server <server>**

When a custom DynDNS provider is used the <server> where update requests are being sent to must be specified.

**set service dns dynamic name <service-name> ip-version ,ipv6'**

Allow explicit IPv6 address for the interface.

### Example:

Use deSEC (dedyn.io) as your preferred provider:

```
set service dns dynamic name dedyn description 'deSEC dynamic dns service'
set service dns dynamic name dedyn username 'myusername'
set service dns dynamic name dedyn password 'mypassword'
set service dns dynamic name dedyn host-name 'myhostname.dedyn.io'
set service dns dynamic name dedyn protocol 'dyndns2'
set service dns dynamic name dedyn server 'update.dedyn.io'
set service dns dynamic name dedyn address interface 'eth0'
```

**Bemerkung:** Multiple services can be used per interface. Just specify as many services per interface as you like!

**Example IPv6 only:**

```
set service dns dynamic name dedyn description 'deSEC ipv6 dynamic dns service'
set service dns dynamic name dedyn username 'myusername'
set service dns dynamic name dedyn password 'mypassword'
set service dns dynamic name dedyn host-name 'myhostname.dedyn.io'
set service dns dynamic name dedyn protocol 'dyndns2'
set service dns dynamic name dedyn ip-version 'ipv6'
set service dns dynamic name dedyn server 'update6.dedyn.io'
set service dns dynamic name dedyn address interface 'eth0'
```

**Running Behind NAT**

By default, `ddclient` will update a dynamic dns record using the IP address directly attached to the interface. If your VyOS instance is behind NAT, your record will be updated to point to your internal IP.

`ddclient` has another way to determine the WAN IP address. This is controlled by:

```
set service dns dynamic name <service-name> address web <url>
```

Use configured `<url>` to determine your IP address. `ddclient` will load `<url>` and tries to extract your IP address from the response.

```
set service dns dynamic name <service-name> address web skip <pattern>
```

`ddclient` will skip any address located before the string set in `<pattern>`.

**8.10.9 Event Handler****Event Handler Technology Overview**

Event handler allows you to execute scripts when a string that matches a regex or a regex with a service name appears in journald logs. You can pass variables, arguments, and a full matching string to the script.

**How to configure Event Handler**

1. *Create an event handler*
2. *Add regex to the script*
3. *Add a full path to the script*
4. *Add optional parameters*

## Event Handler Configuration Steps

### 1. Create an event handler

```
set service event-handler event <event-handler name>
```

This is an optional command because the event handler will be automatically created after any of the next commands.

### 2. Add regex to the script

```
set service event-handler event <event-handler name> filter pattern <regex>
```

This is a mandatory command. Sets regular expression to match against log string message.

---

**Bemerkung:** The regular expression matches if and only if the entire string matches the pattern.

---

### 3. Add a full path to the script

```
set service event-handler event <event-handler name> script path <path to script>
```

This is a mandatory command. Sets the full path to the script. The script file must be executable.

### 4. Add optional parameters

```
set service event-handler event <event-handler name> filter syslog-identifier <sylogid name>
```

This is an optional command. Filters log messages by syslog-identifier.

```
set service event-handler event <event-handler name> script environment <env name> value <env value>
```

This is an optional command. Adds environment and its value to the script. Use separate commands for each environment.

One implicit environment exists.

- message: Full message that has triggered the script.

```
set service event-handler event <event-handler name> script arguments <arguments>
```

This is an optional command. Adds arguments to the script. Arguments must be separated by spaces.

---

**Bemerkung:** We don't recommend to use arguments. Using environments is more preferable.

---

## Example

Event handler that monitors the state of interface eth0.

```
set service event-handler event INTERFACE_STATE_DOWN filter pattern '.*eth0.*',
↳RUNNING,.*->.*'
set service event-handler event INTERFACE_STATE_DOWN filter syslog-identifier
↳'netplugd'
set service event-handler event INTERFACE_STATE_DOWN script environment_
↳interface_action value 'down'
set service event-handler event INTERFACE_STATE_DOWN script environment_
↳interface_name value 'eth2'
set service event-handler event INTERFACE_STATE_DOWN script path '/config/
↳scripts/eventhandler.py'
```

Event handler script

```
#!/usr/bin/env python3
#
# VyOS event-handler script example
from os import environ
import subprocess
from sys import exit

# Perform actions according to requirements
def process_event() -> None:
    # Get variables
    message_text = environ.get('message')
    interface_name = environ.get('interface_name')
    interface_action = environ.get('interface_action')
    # Print the message that triggered this script
    print(f'Logged message: {message_text}')
    # Prepare a command to run
    command = f'sudo ip link set {interface_name} {interface_action}'.split()
    # Execute a command
    subprocess.run(command)

if __name__ == '__main__':
    try:
        # Run script actions and exit
        process_event()
        exit(0)
    except Exception as err:
        # Exit properly in case if something in the script goes wrong
        print(f'Error running script: {err}')
        exit(1)
```

### 8.10.10 HTTP API

VyOS provide an HTTP API. You can use it to execute op-mode commands, update VyOS, set or delete config. Please take a look at the [VyOS API](#) page for an detailed how-to.

#### Configuration

**set service https allow-client address <address>**

Only allow certain IP addresses or prefixes to access the https webserver.

**set service https certificates ca-certificate <name>**

Use CA certificate from PKI subsystem

**set service https certificates certificate <name>**

Use certificate from PKI subsystem

**set service https certificates dh-params <name>**

Use DH parameters from PKI subsystem. Must be at least 2048 bits in length.

**set service https listen-address <address>**

Webserver should only listen on specified IP address

**set service https port <number>**

Webserver should listen on specified port.

Default: 443

**set service https enable-http-redirect**

Enable automatic redirect from http to https.

**set service https tls-version <1.2 | 1.3>**

Select TLS version used.

This defaults to both 1.2 and 1.3.

**set service https vrf <name>**

Start Webserver in given VRF.

**set service https request-body-size-limit <size>**

Set the maximum request body size in megabytes. Default is 1MB.

#### API

**set service https api keys id <name> key <apikey>**

Set a named api key. Every key has the same, full permissions on the system.

**set service https api debug**

To enable debug messages. Available via `show log` or `monitor log`

**set service https api strict**

Enforce strict path checking.

```
set service https api cors allow-origin <origin>
```

Allow cross-origin requests from *<origin>*.

## GraphQL

```
set service https api graphql introspection
```

Enable GraphQL Schema introspection.

---

**Bemerkung:** Do not leave introspection enabled in production, it is a security risk.

---

```
set service https api graphql authentication type <key | token>
```

Set the authentication type for GraphQL, default option is key. Available options are:

- key use API keys configured in `service https api keys`
- token use JWT tokens.

```
set service https api graphql authentication expiration
```

Set the lifetime for JWT tokens in seconds. Default is 3600 seconds.

```
set service https api graphql authentication secret-length
```

Set the byte length of the JWT secret. Default is 32.

## Example Configuration

Set an API-KEY is the minimal configuration to get a working API Endpoint.

```
set service https api keys id MY-HTTPS-API-ID key MY-HTTPS-API-PLAINTEXT-KEY
```

## 8.10.11 DDoS Protection

### FastNetMon

FastNetMon is a high-performance DDoS detector/sensor built on top of multiple packet capture engines: NetFlow, IPFIX, sFlow, AF\_PACKET (port mirror). It can detect hosts in the deployed network sending or receiving large volumes of traffic, packets/bytes/flows per second and perform a configurable action to handle that event, such as calling a custom script.

VyOS includes the FastNetMon Community Edition.

## Configuration

**set service ids ddos-protection alert-script <text>**

Configure alert script that will be executed when an attack is detected.

**set service ids ddos-protection ban-time <1-4294967294>**

Configure how long an IP (attacker) should be kept in blocked state. Default value is 1900.

**set service ids ddos-protection direction [in | out]**

Configure direction for processing traffic.

**set service ids ddos-protection exclude-network <x.x.x.x/x>**

**set service ids ddos-protection exclude-network <h:h:h:h:h:h:h/x>**

Specify IPv4 and/or IPv6 networks which are going to be excluded.

**set service ids ddos-protection listen-interface <text>**

Configure listen interface for mirroring traffic.

**set service ids ddos-protection mode [mirror | sflow]**

Configure traffic capture mode.

**set service ids ddos-protection network <x.x.x.x/x>**

**set service ids ddos-protection network <h:h:h:h:h:h:h/x>**

Specify IPv4 and/or IPv6 networks that should be protected/monitored.

**set service ids ddos-protection sflow listen-address <x.x.x.x>**

Configure local IPv4 address to listen for sflow.

**set service ids ddos-protection sflow port <1-65535>**

Configure port number to be used for sflow connection. Default port is 6343.

**set service ids ddos-protection threshold general [fps | mbps | pps] <0-4294967294>**

Configure general threshold parameters.

**set service ids ddos-protection threshold icmp [fps | mbps | pps] <0-4294967294>**

Configure ICMP threshold parameters.

**set service ids ddos-protection threshold tcp [fps | mbps | pps] <0-4294967294>**

Configure TCP threshold parameters

**set service ids ddos-protection threshold udp [fps | mbps | pps] <0-4294967294>**

Configure UDP threshold parameters

## Example

A configuration example can be found in this section. In this simplified scenario, main things to be considered are:

- Network to be protected: 192.0.2.0/24 (public IPs use by customers)
- **ban-time** and **threshold**: these values are kept very low in order to easily identify and generate an attack.
- Direction: **in** and **out**. Protect public network from external attacks, and identify internal attacks towards internet.
- Interface **eth0** used to connect to upstream.

Since we are analyzing attacks to and from our internal network, two types of attacks can be identified, and different actions are needed:

- External attack: an attack from the internet towards an internal IP is identified. In this case, all connections towards such IP will be blocked
- Internal attack: an attack from the internal network (generated by a customer) towards the internet is identified. In this case, all connections from this particular IP/Customer will be blocked.

So, firewall configuration needed for this setup:

```
set firewall group address-group FNMS-DST-Block
set firewall group address-group FNMS-SRC-Block

set firewall ipv4 forward filter rule 10 action 'drop'
set firewall ipv4 forward filter rule 10 description 'FNMS - block destination'
set firewall ipv4 forward filter rule 10 destination group address-group 'FNMS-DST-Block'

set firewall ipv4 forward filter rule 20 action 'drop'
set firewall ipv4 forward filter rule 20 description 'FNMS - Block source'
set firewall ipv4 forward filter rule 20 source group address-group 'FNMS-SRC-Block'
```

Then, FastNetMon configuration:

```
set service ids ddos-protection alert-script '/config/scripts/fnm-alert.sh'
set service ids ddos-protection ban-time '10'
set service ids ddos-protection direction 'in'
set service ids ddos-protection direction 'out'
set service ids ddos-protection listen-interface 'eth0'
set service ids ddos-protection mode 'mirror'
set service ids ddos-protection network '192.0.2.0/24'
set service ids ddos-protection threshold general pps '100'
```

And content of the script:

```
#!/bin/bash

# alert-script is called twice.
# When an attack occurs, the program calls a bash script twice:
# 1st time when threshold exceed
# 2nd when we collect 100 packets for detailed audit of what happened.

# Do nothing if "attack_details" is passed as an argument
if [ "${4}" == "attack_details" ]; then
    # Do nothing
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

    exit

logger -t FNMS "*** End - Running alert script ***"
exit

```

### 8.10.12 IPoE Server

VyOS utilizes [accel-ppp](#) to provide IPoE (Internet Protocol over Ethernet) server functionality. It can be used with local authentication (mac-address) or a connected RADIUS server.

IPoE is a method of delivering an IP payload over an Ethernet-based access network or an access network using bridged Ethernet over Asynchronous Transfer Mode (ATM) without using PPPoE. It directly encapsulates the IP datagrams in Ethernet frames, using the standard [RFC 894](#) encapsulation.

The use of IPoE addresses the disadvantage that PPP is unsuited for multicast delivery to multiple users. Typically, IPoE uses Dynamic Host Configuration Protocol and Extensible Authentication Protocol to provide the same functionality as PPPoE, but in a less robust manner.

---

**Bemerkung:** Please be aware, due to an upstream bug, config changes/commits will restart the ppp daemon and will reset existing IPoE sessions, in order to become effective.

---

## Configuring IPoE Server

IPoE can be configured on different interfaces, it will depend on each specific situation which interface will provide IPoE to clients. The client's mac address and the incoming interface is being used as control parameter, to authenticate a client.

The example configuration below will assign an IP to the client on the incoming interface eth1 with the client mac address 00:50:79:66:68:00. Other DHCP discovery requests will be ignored, unless the client mac has been enabled in the configuration.

```
set interfaces ethernet eth1 address '192.168.0.1/24'
set service ipoe-server authentication interface eth1.100 mac 00:50:79:66:68:00
set service ipoe-server authentication interface eth1.101 mac 00:50:79:66:68:01
set service ipoe-server authentication mode 'local'
set service ipoe-server client-ip-pool IPOE-POOL range '192.168.0.2-192.168.0.254'
set service ipoe-server default-pool 'IPOE-POOL'
set service ipoe-server gateway-address '192.168.0.1/24'
set service ipoe-server interface eth1 mode 'l2'
set service ipoe-server interface eth1 network 'vlan'
set service ipoe-server interface eth1 vlan '100-200'
```

**set service ipoe-server authentication interface <interface> mac <MAC>**

Creates local IPoE user with username=\*\*<interface>\*\* and password=\*\*<MAC>\*\* (mac-address)

**set service ipoe-server authentication mode <local | radius>**

Set authentication backend. The configured authentication backend is used for all queries.

- **radius:** All authentication queries are handled by a configured RADIUS server.
- **local:** All authentication queries are handled locally.
- **noauth:** Authentication disabled

**set service ipoe-server client-ip-pool <POOL-NAME> range <x.x.x.x-x.x.x.x | x.x.x.x/x>**

Use this command to define the first IP address of a pool of addresses to be given to IPoE clients. If notation x.x.x.x-x.x.x.x, it must be within a /24 subnet. If notation x.x.x.x/x is used there is possibility to set host/netmask.

**set service ipoe-server default-pool <POOL-NAME>**

Use this command to define default address pool name.

**set service ipoe-server gateway-address <x.x.x.x/x>**

Specifies address to be used as server ip address if radius can assign only client address. In such case if client address is matched network and mask then specified address and mask will be used. You can specify multiple such options.

**set service ipoe-server interface <interface> mode <l2 | l3>**

Specifies the client connectivity mode.

- **l2:** It means that clients are on same network where interface is.\*\*(default)\*\*
- **l3:** It means that client are behind some router.

**set service ipoe-server interface <interface> network <shared | vlan>**

Specify where interface is shared by multiple users or it is vlan-per-user.

- **shared:** Multiple clients share the same network. (default)

- **vlan:** One VLAN per client.

```
vyos@vyos:~$ show ipoe-server sessions
```

```

ifname | username |   calling-sid   |   ip   | rate-limit | type | comp | state
↪ | uptime
-----+-----+-----+-----+-----+-----+-----+-----
↪ +-----+
ipoe0  | eth1.100 | 00:50:79:66:68:00 | 192.168.0.2 |           | ipoe |      | active
↪ | 00:04:55
ipoe1  | eth1.101 | 00:50:79:66:68:01 | 192.168.0.3 |           | ipoe |      | active
↪ | 00:04:44

```

## Configuring RADIUS authentication

To enable RADIUS based authentication, the authentication mode needs to be changed within the configuration. Previous settings like the local users, still exists within the configuration, however they are not used if the mode has been changed from local to radius. Once changed back to local, it will use all local accounts again.

```
set service ipoe-server authentication mode radius
```

**set service ipoe-server authentication radius server <server> key <secret>**

Configure RADIUS <server> and its required shared <secret> for communicating with the RADIUS server.

Since the RADIUS server would be a single point of failure, multiple RADIUS servers can be setup and will be used subsequently. For example:

```
set service ipoe-server authentication radius server 10.0.0.1 key 'foo'
set service ipoe-server authentication radius server 10.0.0.2 key 'foo'
```

**Bemerkung:** Some RADIUS servers use an access control list which allows or denies queries, make sure to add your VyOS router to the allowed client list.

## RADIUS source address

If you are using OSPF as IGP, always the closest interface connected to the RADIUS server is used. With VyOS 1.2 you can bind all outgoing RADIUS requests to a single source IP e.g. the loopback interface.

**set service ipoe-server authentication radius source-address <address>**

Source IPv4 address used in all RADIUS server queries.

**Bemerkung:** The source-address must be configured on one of VyOS interface. Best practice would be a loopback or dummy interface.

## RADIUS advanced options

**set service ipoe-server authentication radius server <server> port <port>**

Configure RADIUS <server> and its required port for authentication requests.

**set service ipoe-server authentication radius server <server> fail-time <time>**

Mark RADIUS server as offline for this given <time> in seconds.

**set service ipoe-server authentication radius server <server> disable**

Temporary disable this RADIUS server.

**set service ipoe-server authentication radius acct-timeout <timeout>**

Timeout to wait reply for Interim-Update packets. (default 3 seconds)

**set service ipoe-server authentication radius dynamic-author server <address>**

Specifies IP address for Dynamic Authorization Extension server (DM/CoA)

**set service ipoe-server authentication radius dynamic-author port <port>**

Port for Dynamic Authorization Extension server (DM/CoA)

**set service ipoe-server authentication radius dynamic-author key <secret>**

Secret for Dynamic Authorization Extension server (DM/CoA)

**set service ipoe-server authentication radius max-try <number>**

Maximum number of tries to send Access-Request/Accounting-Request queries

**set service ipoe-server authentication radius timeout <timeout>**

Timeout to wait response from server (seconds)

**set service ipoe-server authentication radius nas-identifier <identifier>**

Value to send to RADIUS server in NAS-Identifier attribute and to be matched in DM/CoA requests.

**set service ipoe-server authentication radius nas-ip-address <address>**

Value to send to RADIUS server in NAS-IP-Address attribute and to be matched in DM/CoA requests. Also DM/CoA server will bind to that address.

**set service ipoe-server authentication radius source-address <address>**

Source IPv4 address used in all RADIUS server queries.

**set service ipoe-server authentication radius rate-limit attribute <attribute>**

Specifies which RADIUS server attribute contains the rate limit information. The default attribute is *Filter-Id*.

---

**Bemerkung:** If you set a custom RADIUS attribute you must define it on both dictionaries at RADIUS server and client.

---

**set service ipoe-server authentication radius rate-limit enable**

Enables bandwidth shaping via RADIUS.

**set service ipoe-server authentication radius rate-limit vendor**

Specifies the vendor dictionary, dictionary needs to be in /usr/share/accel-ppp/radius.

Received RADIUS attributes have a higher priority than parameters defined within the CLI configuration, refer to the explanation below.

### Allocation clients ip addresses by RADIUS

If the RADIUS server sends the attribute Framed-IP-Address then this IP address will be allocated to the client and the option default-pool within the CLI config is being ignored.

If the RADIUS server sends the attribute Framed-Pool, IP address will be allocated from a predefined IP pool whose name equals the attribute value.

If the RADIUS server sends the attribute Stateful-IPv6-Address-Pool, IPv6 address will be allocated from a predefined IPv6 pool prefix whose name equals the attribute value.

If the RADIUS server sends the attribute Delegated-IPv6-Prefix-Pool, IPv6 delegation prefix will be allocated from a predefined IPv6 pool delegate whose name equals the attribute value.

---

**Bemerkung:** Stateful-IPv6-Address-Pool and Delegated-IPv6-Prefix-Pool are defined in RFC6911. If they are not defined in your RADIUS server, add new [dictionary](#).

---

User interface can be put to VRF context via RADIUS Access-Accept packet, or change it via RADIUS CoA. Accel-VRF-Name is used from these purposes. It is custom [ACCEL-PPP attribute](#). Define it in your RADIUS server.

### IPv6

**set service ipoe-server client-ipv6-pool <IPv6-POOL-NAME> prefix <address> mask <number-of-bits>**

Use this comand to set the IPv6 address pool from which an IPoE client will get an IPv6 prefix of your defined length (mask) to terminate the IPoE endpoint at their side. The mask length can be set from 48 to 128 bit long, the default value is 64.

**set service ipoe-server client-ipv6-pool <IPv6-POOL-NAME> delegate <address> delegation-prefix <number-of-bits>**

Use this command to configure DHCPv6 Prefix Delegation (RFC3633) on IPoE. You will have to set your IPv6 pool and the length of the delegation prefix. From the defined IPv6 pool you will be handing out networks of the defined length (delegation-prefix). The length of the delegation prefix can be set from 32 to 64 bit long.

**set service ipoe-server default-ipv6-pool <IPv6-POOL-NAME>**

Use this command to define default IPv6 address pool name.

```
set service ipoe-server client-ipv6-pool IPv6-POOL delegate '2001:db8:8003::/48'
↪delegation-prefix '56'
set service ipoe-server client-ipv6-pool IPv6-POOL prefix '2001:db8:8002::/48' mask '64'
set service ipoe-server default-ipv6-pool IPv6-POOL
```

## Scripting

**set service ipoe-server extended-scripts on-change <path\_to\_script>**

Script to run when session interface changed by RADIUS CoA handling

**set service ipoe-server extended-scripts on-down <path\_to\_script>**

Script to run when session interface going to terminate

**set service ipoe-server extended-scripts on-pre-up <path\_to\_script>**

Script to run before session interface comes up

**set service ipoe-server extended-scripts on-up <path\_to\_script>**

Script to run when session interface is completely configured and started

## Advanced Options

### Authentication Advanced Options

**set service ipoe-server authentication interface <interface> mac <MAC> vlan <vlan-id>**

VLAN monitor for automatic creation of VLAN interfaces for specific user on specific <interface>

**set service ipoe-server authentication interface <interface> mac <MAC> rate-limit download <bandwidth>**

Download bandwidth limit in kbit/s for user on interface <interface>.

**set service ipoe-server authentication interface <interface> mac <MAC> rate-limit upload <bandwidth>**

Upload bandwidth limit in kbit/s for for user on interface <interface>.

### Client IP Pool Advanced Options

**set service ipoe-server client-ip-pool <POOL-NAME> next-pool <NEXT-POOL-NAME>**

Use this command to define the next address pool name.

### Advanced Interface Options

**set service ipoe-server interface <interface> client-subnet <x.x.x.x/x>**

Specify local range of ip address to give to dhcp clients. First IP in range is router IP. If you need more customization use *client-ip-pool*

**set service ipoe-server interface <interface> external-dhcp dhcp-relay <x.x.x.x>**

Specify DHCPv4 relay IP address to pass requests to. If specified giaddr is also needed.

**set service ipoe-server interface <interface> external-dhcp giaddr <x.x.x.x>**

Specifies relay agent IP addre

## Global Advanced options

**set service ipoe-server description <description>**

Set description.

**set service ipoe-server limits burst <value>**

Burst count

**set service ipoe-server limits connection-limit <value>**

Acceptable rate of connections (e.g. 1/min, 60/sec)

**set service ipoe-server limits timeout <value>**

Timeout in seconds

**set service ipoe-server max-concurrent-sessions**

Maximum number of concurrent session start attempts

**set service ipoe-server name-server <address>**

Connected client should use <address> as their DNS server. This command accepts both IPv4 and IPv6 addresses. Up to two nameservers can be configured for IPv4, up to three for IPv6.

**set service ipoe-server shaper fwmark <1-2147483647>**

Match firewall mark value

**set service ipoe-server snmp master-agent**

Enable SNMP

## Monitoring

**show ipoe-server sessions**

Use this command to locally check the active sessions in the IPoE server.

```
vyos@vyos:~$ show ipoe-server sessions
ifname | username | calling-sid | ip | rate-limit | type | comp | state
--|-----
eth1.100 | eth1.100 | 0c:98:bd:b8:00:01 | 192.168.0.3 | | ipoe |
active | 03:03:58
```

**show ipoe-server statistics**

```
uptime: 0.03:31:36
cpu: 0%
mem(rss/virt): 6044/101360 kB

### 8.10.13 LLDP

LLDP (Link Layer Discovery Protocol) is a vendor-neutral link layer protocol in the Internet Protocol Suite used by network devices for advertising their identity, capabilities, and neighbors on an IEEE 802 local area network, principally wired Ethernet. The protocol is formally referred to by the IEEE as Station and Media Access Control Connectivity Discovery specified in IEEE 802.1AB and IEEE 802.3-2012 section 6 clause 79.

LLDP performs functions similar to several proprietary protocols, such as CDP (Cisco Discovery Protocol), FDP (Foundry Discovery Protocol), NDP (Nortel Discovery Protocol) and LLTD (Link Layer Topology Discovery).

Information gathered with LLDP is stored in the device as a MIB (Management Information Database) and can be queried with SNMP (Simple Network Management Protocol) as specified in [RFC 2922](#). The topology of an LLDP-

enabled network can be discovered by crawling the hosts and querying this database. Information that may be retrieved include:

- System Name and Description
- Port name and description
- VLAN name
- IP management address
- System capabilities (switching, routing, etc.)
- MAC/PHY information
- MDI power
- Link aggregation

## Configuration

### **set service lldp**

Enable LLDP service

### **set service lldp management-address <address>**

Define IPv4/IPv6 management address transmitted via LLDP. Multiple addresses can be defined. Only addresses connected to the system will be transmitted.

### **set service lldp interface <interface>**

Enable transmission of LLDP information on given <interface>. You can also say `all` here so LLDP is turned on on every interface.

### **set service lldp interface <interface> disable**

Disable transmit of LLDP frames on given <interface>. Useful to exclude certain interfaces from LLDP when `all` have been enabled.

### **set service lldp snmp**

Enable SNMP queries of the LLDP database

### **set service lldp legacy-protocols <cdp|edp|fdp|sonmp>**

Enable given legacy protocol on this LLDP instance. Legacy protocols include:

- `cdp` - Listen for CDP for Cisco routers/switches
- `edp` - Listen for EDP for Extreme routers/switches
- `fdp` - Listen for FDP for Foundry routers/switches
- `sonmp` - Listen for SONMP for Nortel routers/switches

## Operation

### show lldp neighbors

Displays information about all neighbors discovered via LLDP.

```
vyos@vyos:~$ show lldp neighbors
Capability Codes: R - Router, B - Bridge, W - Wlan r - Repeater, S - Station
                  D - Docsis, T - Telephone, O - Other

Device ID          Local    Proto  Cap  Platform          Port ID
-----
BR2.vyos.net       eth0    LLDP   R    VyOS 1.2.4        eth1

**show lldp neighbors interface <interface>**

Show LLDP neighbors connected via interface <interface>.

**show log lldp**

Used for troubleshooting.

**8.10.14 mDNS Repeater**

Starting with VyOS 1.2 a mDNS (Multicast DNS) repeater functionality is provided. Additional information can be obtained from [https://en.wikipedia.org/wiki/Multicast\\_DNS](https://en.wikipedia.org/wiki/Multicast_DNS).

Multicast DNS uses the reserved address 224.0.0.251, which is „*administratively scoped*“ and does not leave the subnet. mDNS repeater retransmits mDNS packets from one interface to other interfaces. This enables support for devices using mDNS discovery (like network printers, Apple Airplay, Chromecast, various IP based home-automation devices etc) across multiple VLANs.

Since the mDNS protocol sends the AA (Authoritative Answer) records in the packet itself, the repeater does not need to forge the source address. Instead, the source address is of the interface that repeats the packet.

**Configuration****set service mdns repeater interface <interface>**

To enable mDNS repeater you need to configure at least two interfaces so that all incoming mDNS packets from one interface configured here can be re-broadcasted to any other interface(s) configured under this section.

**set service mdns repeater disable**

mDNS repeater can be temporarily disabled without deleting the service using

**set service mdns repeater ip-version <ipv4 | ipv6 | both>**

mDNS repeater can be enabled either on IPv4 socket or on IPv6 socket or both to re-broadcast. By default, mDNS repeater will listen on both IPv4 and IPv6.

**set service mdns repeater allow-service <service>**

mDNS repeater can be configured to re-broadcast only specific services. By default, all services are re-broadcasted.

**set service mdns repeater browse-domain <domain>**

Allow listing additional custom domains to be browsed (in addition to the default local) so that they can be reflected.

---

**Bemerkung:** You can not run this in a VRRP setup, if multiple mDNS repeaters are launched in a subnet you will experience the mDNS packet storm death!

---

## Example

To listen on both *eth0* and *eth1* mDNS packets and also repeat packets received on *eth0* to *eth1* (and vice-versa) use the following commands:

```
set service mdns repeater interface 'eth0'
set service mdns repeater interface 'eth1'
```

To allow only specific services, for example *\_airplay.\_tcp* or *\_ipp.\_tcp*, (instead of all services) to be re-broadcasted, use the following command:

```
set service mdns repeater allow-service '_airplay._tcp'
set service mdns repeater allow-service '_ipp._tcp'
```

To allow listing additional custom domain, for example *openthread.thread.home.arpa*, so that it can be reflected in addition to the default *local*, use the following command:

```
set service mdns repeater browse-domain 'openthread.thread.home.arpa'
```

## Operation

### **restart mdns repeater**

Restart mDNS repeater service.

### **show log mdns repeater**

Show logs for mDNS repeater service.

### **monitor log mdns repeater**

Follow the logs for mDNS repeater service.

## 8.10.15 Monitoring

### Azure-data-explorer

Telegraf output plugin [azure-data-explorer](#)

```
set service monitoring telegraf azure-data-explorer authentication client-id <client-id>
```

Authentication application client-id.

```
set service monitoring telegraf azure-data-explorer authentication client-secret
<client-secret>
```

Authentication application client-secret.

```
set service monitoring telegraf azure-data-explorer authentication tenant-id <tenant-id>
```

Authentication application tenant-id

```
set service monitoring telegraf azure-data-explorer database <name>
```

Remote database name.

```
set service monitoring telegraf azure-data-explorer group-metrics <single-table |
table-per-metric>
```

Type of metrics grouping when push to Azure Data Explorer. The default is *table-per-metric*.

```
set service monitoring telegraf azure-data-explorer table <name>
```

Name of the single table Only if set group-metrics single-table.

```
set service monitoring telegraf azure-data-explorer url <url>
```

Remote URL.

## Prometheus-client

Telegraf output plugin [prometheus-client](#)

```
set service monitoring telegraf prometheus-client
```

Output plugin Prometheus client

```
set service monitoring telegraf prometheus-client allow-from <prefix>
```

Networks allowed to query this server

```
set service monitoring telegraf prometheus-client authentication username <username>
```

HTTP basic authentication username

```
set service monitoring telegraf prometheus-client authentication password <password>
```

HTTP basic authentication password

```
set service monitoring telegraf prometheus-client listen-address <address>
```

Local IP addresses to listen on

```
set service monitoring telegraf prometheus-client metric-version <1 | 2>
```

Metris version, the default is 2

```
set service monitoring telegraf prometheus-client port <port>
```

Port number used by connection, default is 9273

Example:

```
set service monitoring telegraf prometheus-client
```

```
vyos@r14:~$ curl --silent localhost:9273/metrics | egrep -v "#" | grep cpu_usage_system
cpu_usage_system{cpu="cpu-total",host="r14"} 0.20040080160320556
cpu_usage_system{cpu="cpu0",host="r14"} 0.17182130584191915
cpu_usage_system{cpu="cpu1",host="r14"} 0.22896393817971655
```

## Splunk

Telegraf output plugin [splunk](#). HTTP Event Collector.

```
set service monitoring telegraf splunk authentication insecure
```

Use TLS but skip host validation

```
set service monitoring telegraf splunk authentication token <token>
```

Authorization token

```
set service monitoring telegraf splunk authentication url <url>
```

Remote URL to Splunk collector

Example:

```
set service monitoring telegraf splunk authentication insecure
set service monitoring telegraf splunk authentication token 'xxxxf5b8-xxxx-452a-xxxx-
↪43828911xxxx'
set service monitoring telegraf splunk url 'https://192.0.2.10:8088/services/collector'
```

## Telegraf

Monitoring functionality with telegraf and InfluxDB 2 is provided. Telegraf is the open source server agent to help you collect metrics, events and logs from your routers.

```
set service monitoring telegraf influxdb authentication organization <organization>
```

Authentication organization name

```
set service monitoring telegraf influxdb authentication token <token>
```

Authentication token

```
set service monitoring telegraf bucket <bucket>
```

Remote InfluxDB bucket name

```
set service monitoring telegraf influxdb port <port>
```

Remote port

```
set service monitoring telegraf influxdb url <url>
```

Remote URL

## Example

An example of a configuration that sends telegraf metrics to remote InfluxDB 2

```
set service monitoring telegraf influxdb authentication organization 'vyos'
set service monitoring telegraf influxdb authentication token 'ZAm19Uy5wrhA...=='
set service monitoring telegraf influxdb bucket 'bucket_vyos'
set service monitoring telegraf influxdb port '8086'
set service monitoring telegraf influxdb url 'http://r1.influxdb2.local'
```

## 8.10.16 NTP

NTP (NETWORK TIME PROTOCOL) is a networking protocol for clock synchronization between computer systems over packet-switched, variable-latency data networks. In operation since before 1985, NTP is one of the oldest Internet protocols in current use.

NTP is intended to synchronize all participating computers to within a few milliseconds of UTC (Coordinated Universal Time). It uses the intersection algorithm, a modified version of Marzullo's algorithm, to select accurate time servers and is designed to mitigate the effects of variable network latency. NTP can usually maintain time to within tens of milliseconds over the public Internet, and can achieve better than one millisecond accuracy in local area networks under ideal conditions. Asymmetric routes and network congestion can cause errors of 100 ms or more.

The protocol is usually described in terms of a client-server model, but can as easily be used in peer-to-peer relationships where both peers consider the other to be a potential time source. Implementations send and receive timestamps using UDP (User Datagram Protocol) on port number 123.

NTP supplies a warning of any impending leap second adjustment, but no information about local time zones or daylight saving time is transmitted.

The current protocol is version 4 (NTPv4), which is a proposed standard as documented in [RFC 5905](#). It is backward compatible with version 3, specified in [RFC 1305](#).

---

**Bemerkung:** VyOS 1.4 uses chrony instead of ntpd (see [T3008](#)) which will no longer accept anonymous NTP requests as in VyOS 1.3. All configurations will be migrated to keep the anonymous functionality. For new setups if you have clients using your VyOS installation as NTP server, you must specify the *allow-client* directive.

---

## Configuration

**set service ntp server <address>**

Configure one or more servers for synchronisation. Server name can be either an IP address or FQDN (Fully Qualified Domain Name).

There are 3 default NTP server set. You are able to change them.

- time1.vyos.net
- time2.vyos.net
- time3.vyos.net

**set service ntp server <address> <noselect | nts | pool | prefer>**

Configure one or more attributes to the given NTP server.

- **noselect** marks the server as unused, except for display purposes. The server is discarded by the selection algorithm.
- **nts** enables Network Time Security (NTS) for the server as specified in [RFC 8915](#)
- **pool** mobilizes persistent client mode association with a number of remote servers.
- **prefer** marks the server as preferred. All other things being equal, this host will be chosen for synchronization among a set of correctly operating hosts.

**set service ntp listen-address <address>**

NTP process will only listen on the specified IP address. You must specify the <address> and optionally the permitted clients. Multiple listen addresses can be configured.

**set service ntp allow-client address <address>**

List of networks or client addresses permitted to contact this NTP server.

Multiple networks/client IP addresses can be configured.

**set service ntp vrf <name>**

Specify name of the VRF (Virtual Routing and Forwarding) instance.

**set service ntp leap-second [ignore|smear|system|timezone]**

Define how to handle leap-seconds.

- **ignore:** No correction is applied to the clock for the leap second. The clock will be corrected later in normal operation when new measurements are made and the estimated offset includes the one second error.

- *smear*: When smearing a leap second, the leap status is suppressed on the server and the served time is corrected slowly by slewing instead of stepping. The clients do not need any special configuration as they do not know there is any leap second and they follow the server time which eventually brings them back to UTC. Care must be taken to ensure they use only NTP servers which smear the leap second in exactly the same way for synchronisation.
- *system*: When inserting a leap second, the kernel steps the system clock backwards by one second when the clock gets to 00:00:00 UTC. When deleting a leap second, it steps forward by one second when the clock gets to 23:59:59 UTC.
- *timezone*: This directive specifies a timezone in the system timezone database which chronyd can use to determine when will the next leap second occur and what is the current offset between TAI and UTC. It will periodically check if 23:59:59 and 23:59:60 are valid times in the timezone. This normally works with the right/UTC timezone which is the default

### 8.10.17 PPPoE Server

VyOS utilizes `accel-ppp` to provide PPPoE server functionality. It can be used with local authentication or a connected RADIUS server.

**Bemerkung:** Please be aware, due to an upstream bug, config changes/commits will restart the ppp daemon and will reset existing PPPoE connections from connected users, in order to become effective.

#### Configuring PPPoE Server

```
set service pppoe-server access-concentrator PPPoE-Server
set service pppoe-server authentication mode local
set service pppoe-server authentication local-users username test password 'test'
set service pppoe-server client-ip-pool PPPoE-POOL range 192.168.255.2-192.168.255.254
set service pppoe-server default-pool 'PPPoE-POOL'
set service pppoe-server gateway-address 192.168.255.1
set service pppoe-server interface eth0
```

**set service pppoe-server access-concentrator <name>**

Use this command to set a name for this PPPoE-server access concentrator.

**set service pppoe-server authentication mode <local | radius>**

Set authentication backend. The configured authentication backend is used for all queries.

- **radius**: All authentication queries are handled by a configured RADIUS server.
- **local**: All authentication queries are handled locally.
- **noauth**: Authentication disabled.

**set service pppoe-server authentication local-users username <name> password <password>**

Create <user> for local authentication on this system. The users password will be set to <pass>.

**set service pppoe-server client-ip-pool <POOL-NAME> range <x.x.x.x-x.x.x.x | x.x.x.x/x>**

Use this command to define the first IP address of a pool of addresses to be given to pppoe clients. If notation `x.x.x.x-x.x.x.x`, it must be within a /24 subnet. If notation `x.x.x.x/x` is used there is possibility to set host/netmask.

```
set service pppoe-server default-pool <POOL-NAME>
```

Use this command to define default address pool name.

```
set service pppoe-server interface <interface>
```

Use this command to define the interface the PPPoE server will use to listen for PPPoE clients.

```
set service pppoe-server gateway-address <address>
```

Specifies single <gateway> IP address to be used as local address of PPP interfaces.

## Configuring RADIUS authentication

To enable RADIUS based authentication, the authentication mode needs to be changed within the configuration. Previous settings like the local users, still exists within the configuration, however they are not used if the mode has been changed from local to radius. Once changed back to local, it will use all local accounts again.

```
set service pppoe-server authentication mode radius
```

```
set service pppoe-server authentication radius server <server> key <secret>
```

Configure RADIUS <server> and its required shared <secret> for communicating with the RADIUS server.

Since the RADIUS server would be a single point of failure, multiple RADIUS servers can be setup and will be used subsequently. For example:

```
set service pppoe-server authentication radius server 10.0.0.1 key 'foo'
set service pppoe-server authentication radius server 10.0.0.2 key 'foo'
```

---

**Bemerkung:** Some RADIUS servers use an access control list which allows or denies queries, make sure to add your VyOS router to the allowed client list.

---

## RADIUS source address

If you are using OSPF as IGP, always the closest interface connected to the RADIUS server is used. With VyOS 1.2 you can bind all outgoing RADIUS requests to a single source IP e.g. the loopback interface.

```
set service pppoe-server authentication radius source-address <address>
```

Source IPv4 address used in all RADIUS server queries.

---

**Bemerkung:** The source-address must be configured on one of VyOS interface. Best practice would be a loopback or dummy interface.

---

## RADIUS advanced options

**set service pppoe-server authentication radius server <server> port <port>**

Configure RADIUS <server> and its required port for authentication requests.

**set service pppoe-server authentication radius server <server> fail-time <time>**

Mark RADIUS server as offline for this given <time> in seconds.

**set service pppoe-server authentication radius server <server> disable**

Temporary disable this RADIUS server.

**set service pppoe-server authentication radius acct-timeout <timeout>**

Timeout to wait reply for Interim-Update packets. (default 3 seconds)

**set service pppoe-server authentication radius dynamic-author server <address>**

Specifies IP address for Dynamic Authorization Extension server (DM/CoA)

**set service pppoe-server authentication radius dynamic-author port <port>**

Port for Dynamic Authorization Extension server (DM/CoA)

**set service pppoe-server authentication radius dynamic-author key <secret>**

Secret for Dynamic Authorization Extension server (DM/CoA)

**set service pppoe-server authentication radius max-try <number>**

Maximum number of tries to send Access-Request/Accounting-Request queries

**set service pppoe-server authentication radius timeout <timeout>**

Timeout to wait response from server (seconds)

**set service pppoe-server authentication radius nas-identifier <identifier>**

Value to send to RADIUS server in NAS-Identifier attribute and to be matched in DM/CoA requests.

**set service pppoe-server authentication radius nas-ip-address <address>**

Value to send to RADIUS server in NAS-IP-Address attribute and to be matched in DM/CoA requests. Also DM/CoA server will bind to that address.

**set service pppoe-server authentication radius source-address <address>**

Source IPv4 address used in all RADIUS server queries.

**set service pppoe-server authentication radius rate-limit attribute <attribute>**

Specifies which RADIUS server attribute contains the rate limit information. The default attribute is Filter-Id.

---

**Bemerkung:** If you set a custom RADIUS attribute you must define it on both dictionaries at RADIUS server and client.

---

**set service pppoe-server authentication radius rate-limit enable**

Enables bandwidth shaping via RADIUS.

**set service pppoe-server authentication radius rate-limit vendor**

Specifies the vendor dictionary, dictionary needs to be in /usr/share/accel-ppp/radius.

Received RADIUS attributes have a higher priority than parameters defined within the CLI configuration, refer to the explanation below.

### Allocation clients ip addresses by RADIUS

If the RADIUS server sends the attribute `Framed-IP-Address` then this IP address will be allocated to the client and the option `default-pool` within the CLI config is being ignored.

If the RADIUS server sends the attribute `Framed-Pool`, IP address will be allocated from a predefined IP pool whose name equals the attribute value.

If the RADIUS server sends the attribute `Stateful-IPv6-Address-Pool`, IPv6 address will be allocated from a predefined IPv6 pool `prefix` whose name equals the attribute value.

If the RADIUS server sends the attribute `Delegated-IPv6-Prefix-Pool`, IPv6 delegation prefix will be allocated from a predefined IPv6 pool `delegate` whose name equals the attribute value.

---

**Bemerkung:** `Stateful-IPv6-Address-Pool` and `Delegated-IPv6-Prefix-Pool` are defined in RFC6911. If they are not defined in your RADIUS server, add new [dictionary](#).

---

User interface can be put to VRF context via RADIUS Access-Accept packet, or change it via RADIUS CoA. `Accel-VRF-Name` is used from these purposes. It is custom [ACCEL-PPP attribute](#). Define it in your RADIUS server.

### Renaming clients interfaces by RADIUS

If the RADIUS server uses the attribute `NAS-Port-Id`, ppp tunnels will be renamed.

---

**Bemerkung:** The value of the attribute `NAS-Port-Id` must be less than 16 characters, otherwise the interface won't be renamed.

---

### Automatic VLAN Creation

**set service pppoe-server interface <interface> vlan <id | range>**

VLAN's can be created by Accel-ppp on the fly via the use of a Kernel module named `vlan_mon`, which is monitoring incoming vlans and creates the necessary VLAN if required and allowed. VyOS supports the use of either VLAN ID's or entire ranges, both values can be defined at the same time for an interface.

When configured, PPPoE will create the necessary VLANs when required. Once the user session has been cancelled and the VLAN is not needed anymore, VyOS will remove it again.

```
set service pppoe-server interface eth3 vlan 100
set service pppoe-server interface eth3 vlan 200
set service pppoe-server interface eth3 vlan 500-1000
set service pppoe-server interface eth3 vlan 2000-3000
```

## Bandwidth Shaping

Bandwidth rate limits can be set for local users or RADIUS based attributes.

### For Local Users

```
set service pppoe-server authentication local-users username <user> rate-limit download <bandwidth>
```

Download bandwidth limit in kbit/s for <user>.

```
set service pppoe-server authentication local-users username <user> rate-limit upload <bandwidth>
```

Upload bandwidth limit in kbit/s for <user>.

```
set service pppoe-server access-concentrator 'ACN'
set service pppoe-server authentication local-users username foo password 'bar'
set service pppoe-server authentication local-users username foo rate-limit download
↳ '20480'
set service pppoe-server authentication local-users username foo rate-limit upload '10240
↳ '
set service pppoe-server authentication mode 'local'
set service pppoe-server client-ip-pool IP-POOL range '10.1.1.100/24'
set service pppoe-server default-pool 'IP-POOL'
set service pppoe-server name-server '10.100.100.1'
set service pppoe-server name-server '10.100.200.1'
set service pppoe-server interface 'eth1'
set service pppoe-server gateway-address '10.1.1.2'
```

Once the user is connected, the user session is using the set limits and can be displayed via `show pppoe-server sessions`.

```
show pppoe-server sessions
ifname | username | ip | calling-sid | rate-limit | state | uptime |
↳ rx-bytes | tx-bytes
-----+-----+-----+-----+-----+-----+-----+-----
↳ -----+-----
ppp0 | foo | 10.1.1.100 | 00:53:00:ba:db:15 | 20480/10240 | active | 00:00:11 |
↳ 214 B | 76 B
```

### For RADIUS users

The current attribute `Filter-Id` is being used as default and can be setup within RADIUS:

`Filter-Id=2000/3000` (means 2000Kbit down-stream rate and 3000Kbit up-stream rate)

The command below enables it, assuming the RADIUS connection has been setup and is working.

```
set service pppoe-server authentication radius rate-limit enable
```

Use this command to enable bandwidth shaping via RADIUS.

Other attributes can be used, but they have to be in one of the dictionaries in `/usr/share/accel-ppp/radius`.

## Load Balancing

**set service pppoe-server pado-delay <number-of-ms> sessions <number-of-sessions>**

Use this command to enable the delay of PADO (PPPoE Active Discovery Offer) packets, which can be used as a session balancing mechanism with other PPPoE servers.

```
set service pppoe-server pado-delay 50 sessions '500'
set service pppoe-server pado-delay 100 sessions '1000'
set service pppoe-server pado-delay 300 sessions '3000'
```

In the example above, the first 499 sessions connect without delay. PADO packets will be delayed 50 ms for connection from 500 to 999, this trick allows other PPPoE servers send PADO faster and clients will connect to other servers. Last command says that this PPPoE server can serve only 3000 clients.

## IPv6

**set service pppoe-server ppp-options ipv6 <require | prefer | allow | deny>**

Specifies IPv6 negotiation preference.

- **require** - Require IPv6 negotiation
- **prefer** - Ask client for IPv6 negotiation, do not fail if it rejects
- **allow** - Negotiate IPv6 only if client requests
- **deny** - Do not negotiate IPv6 (default value)

**set service pppoe-server client-ipv6-pool <IPv6-POOL-NAME> prefix <address> mask <number-of-bits>**

Use this command to set the IPv6 address pool from which an PPPoE client will get an IPv6 prefix of your defined length (mask) to terminate the PPPoE endpoint at their side. The mask length can be set from 48 to 128 bit long, the default value is 64.

**set service pppoe-server client-ipv6-pool <IPv6-POOL-NAME> delegate <address> delegation-prefix <number-of-bits>**

Use this command to configure DHCPv6 Prefix Delegation (RFC3633) on PPPoE. You will have to set your IPv6 pool and the length of the delegation prefix. From the defined IPv6 pool you will be handing out networks of the defined length (delegation-prefix). The length of the delegation prefix can be set from 32 to 64 bit long.

**set service pppoe-server default-ipv6-pool <IPv6-POOL-NAME>**

Use this command to define default IPv6 address pool name.

```
set service pppoe-server ppp-options ipv6 allow
set service pppoe-server client-ipv6-pool IPv6-POOL delegate '2001:db8:8003::/48'
↪delegation-prefix '56'
set service pppoe-server client-ipv6-pool IPv6-POOL prefix '2001:db8:8002::/48' mask '64'
set service pppoe-server default-ipv6-pool IPv6-POOL
```

## IPv6 Advanced Options

**set service pppoe-server ppp-options ipv6-accept-peer-interface-id**

Accept peer interface identifier. By default is not defined.

**set service pppoe-server ppp-options ipv6-interface-id <random | x:x:x:x>**

Specifies fixed or random interface identifier for IPv6. By default is fixed.

- **random** - Random interface identifier for IPv6
- **x:x:x:x** - Specify interface identifier for IPv6

**set service pppoe-server ppp-options ipv6-interface-id <random | x:x:x:x>**

Specifies peer interface identifier for IPv6. By default is fixed.

- **random** - Random interface identifier for IPv6
- **x:x:x:x** - Specify interface identifier for IPv6
- **ipv4-addr** - Calculate interface identifier from IPv4 address.
- **calling-sid** - Calculate interface identifier from calling-station-id.

## Scripting

**set service pppoe-server extended-scripts on-change <path\_to\_script>**

Script to run when session interface changed by RADIUS CoA handling

**set service pppoe-server extended-scripts on-down <path\_to\_script>**

Script to run when session interface going to terminate

**set service pppoe-server extended-scripts on-pre-up <path\_to\_script>**

Script to run before session interface comes up

**set service pppoe-server extended-scripts on-up <path\_to\_script>**

Script to run when session interface is completely configured and started

## Advanced Options

### Authentication Advanced Options

**set service pppoe-server authentication local-users username <user> disable**

Disable <user> account.

**set service pppoe-server authentication local-users username <user> static-ip <address>**

Assign static IP address to <user> account.

**set service pppoe-server authentication protocols <pap | chap | mschap | mschap-v2>**

Require the peer to authenticate itself using one of the following protocols: pap, chap, mschap, mschap-v2.

## Client IP Pool Advanced Options

**set service pppoe-server client-ip-pool <POOL-NAME> next-pool <NEXT-POOL-NAME>**

Use this command to define the next address pool name.

## PPP Advanced Options

**set service pppoe-server ppp-options disable-ccp**

Disable Compression Control Protocol (CCP). CCP is enabled by default.

**set service pppoe-server ppp-options interface-cache <number>**

Specifies number of interfaces to keep in cache. It means that don't destroy interface after corresponding session is destroyed, instead place it to cache and use it later for new sessions repeatedly. This should reduce kernel-level interface creation/deletion rate lack. Default value is **0**.

**set service pppoe-server ppp-options ipv4 <require | prefer | allow | deny>**

Specifies IPv4 negotiation preference.

- **require** - Require IPv4 negotiation
- **prefer** - Ask client for IPv4 negotiation, do not fail if it rejects
- **allow** - Negotiate IPv4 only if client requests (Default value)
- **deny** - Do not negotiate IPv4

**set service pppoe-server ppp-options lcp-echo-failure <number>**

Defines the maximum <number> of unanswered echo requests. Upon reaching the value <number>, the session will be reset. Default value is **3**.

**set service pppoe-server ppp-options lcp-echo-interval <interval>**

If this option is specified and is greater than 0, then the PPP module will send LCP pings of the echo request every <interval> seconds. Default value is **30**.

**set service pppoe-server ppp-options lcp-echo-timeout**

Specifies timeout in seconds to wait for any peer activity. If this option specified it turns on adaptive lcp echo functionality and „lcp-echo-failure“ is not used. Default value is **0**.

**set service pppoe-server ppp-options min-mtu <number>**

Defines minimum acceptable MTU. If client will try to negotiate less then specified MTU then it will be NAKed or disconnected if rejects greater MTU. Default value is **100**.

**set service pppoe-server ppp-options mppe <require | prefer | deny>**

Specifies MPPE (Microsoft Point-to-Point Encryption) negotiation preference.

- **require** - ask client for mppe, if it rejects drop connection
- **prefer** - ask client for mppe, if it rejects don't fail. (Default value)
- **deny** - deny mppe

Default behavior - don't ask client for mppe, but allow it if client wants. Please note that RADIUS may override this option by MS-MPPE-Encryption-Policy attribute.

**set service pppoe-server ppp-options mru <number>**

Defines preferred MRU. By default is not defined.

## Global Advanced options

**set service pppoe-server description <description>**

Set description.

**set service pppoe-server limits burst <value>**

Burst count

**set service pppoe-server limits connection-limit <value>**

Acceptable rate of connections (e.g. 1/min, 60/sec)

**set service pppoe-server limits timeout <value>**

Timeout in seconds

**set service pppoe-server mtu**

Maximum Transmission Unit (MTU) (default: **1492**)

**set service pppoe-server max-concurrent-sessions**

Maximum number of concurrent session start attempts

**set service pppoe-server name-server <address>**

Connected client should use <address> as their DNS server. This command accepts both IPv4 and IPv6 addresses. Up to two nameservers can be configured for IPv4, up to three for IPv6.

**set service pppoe-server service-name <names>**

Specifies Service-Name to respond. If absent any Service-Name is acceptable and client's Service-Name will be sent back. Also possible set multiple service-names: *sn1,sn2,sn3*

Per default the user session is being replaced if a second authentication request succeeds. Such session requests can be either denied or allowed entirely, which would allow multiple sessions for a user in the latter case. If it is denied, the second session is being rejected even if the authentication succeeds, the user has to terminate its first session and can then authentication again.

**set service pppoe-server session-control**

- **disable**: Disables session control.
- **deny**: Deny second session authorization.
- **replace**: Terminate first session when second is authorized (**default**)

**set service pppoe-server shaper fwmark <1-2147483647>**

Match firewall mark value

**set service pppoe-server snmp master-agent**

Enable SNMP

**set service pppoe-server wins-server <address>**

Windows Internet Name Service (WINS) servers propagated to client

## Monitoring

### show pppoe-server sessions

Use this command to locally check the active sessions in the PPPoE server.

```
show pppoe-server sessions
ifname | username | ip | calling-sid | rate-limit | state | uptime |
↳ rx-bytes | tx-bytes
-----+-----+-----+-----+-----+-----+-----+
↳ -----+-----+
ppp0 | foo | 10.1.1.100 | 00:53:00:ba:db:15 | 20480/10240 | active | 00:00:11 |
↳ 214 B | 76 B
```

## Examples

### IPv4

The example below uses ACN as access-concentrator name, assigns an address from the pool 10.1.1.100-111, terminates at the local endpoint 10.1.1.1 and serves requests only on eth1.

```
set service pppoe-server access-concentrator 'ACN'
set service pppoe-server authentication local-users username foo password 'bar'
set service pppoe-server authentication mode 'local'
set service pppoe-server client-ip-pool IP-POOL range '10.1.1.100-10.1.1.111'
set service pppoe-server default-pool 'IP-POOL'
set service pppoe-server interface eth1
set service pppoe-server gateway-address '10.1.1.2'
set service pppoe-server name-server '10.100.100.1'
set service pppoe-server name-server '10.100.200.1'
```

### Dual-Stack IPv4/IPv6 provisioning with Prefix Delegation

The example below covers a dual-stack configuration.

```
set service pppoe-server authentication local-users username test password 'test'
set service pppoe-server authentication mode 'local'
set service pppoe-server client-ip-pool IP-POOL range '192.168.0.1/24'
set service pppoe-server default-pool 'IP-POOL'
set service pppoe-server client-ipv6-pool IPv6-POOL delegate '2001:db8:8003::/48'
↳ delegation-prefix '56'
set service pppoe-server client-ipv6-pool IPV6-POOL prefix '2001:db8:8002::/48' mask '64'
set service pppoe-server default-ipv6-pool IPv6-POOL
set service pppoe-server ppp-options ipv6 allow
set service pppoe-server name-server '10.1.1.1'
set service pppoe-server name-server '2001:db8:4860::8888'
set service pppoe-server interface 'eth2'
set service pppoe-server gateway-address '10.100.100.1'
```

The client, once successfully authenticated, will receive an IPv4 and an IPv6 /64 address to terminate the PPPoE endpoint on the client side and a /56 subnet for the clients internal use.

```
vyos@pppoe-server:~$ sh pppoe-server sessions
ifname | username | ip | ip6 | ip6-dp |
↳calling-sid | rate-limit | state | uptime | rx-bytes | tx-bytes
-----+-----+-----+-----+-----+-----
↳-----+-----+-----+-----+-----+-----
ppp0 | test | 192.168.0.1 | 2001:db8:8002:0:200::/64 | 2001:db8:8003::1/56 |
↳00:53:00:12:42:eb | | active | 00:00:49 | 875 B | 2.1 KiB
```

### 8.10.18 Router Advertisements

RAs (Router advertisements) are described in [RFC 4861#section-4.6.2](#). They are part of what is known as SLAAC.

Supported interface types:

- bonding
- bridge
- ethernet
- geneve
- l2tpv3
- openvpn
- pseudo-ethernet
- tunnel
- vxlan
- wireguard
- wireless
- wwan

## Configuration

**set service router-advert interface <interface> ...**

Field	VyOS Option	Description
Cur Hop Limit	hop-limit	Hop count field of the outgoing RA packets
„Managed address configuration“ flag	managed-flag	Tell hosts to use the administered stateful protocol (i.e. DHCP) for autoconfiguration
„Other configuration“ flag	other-config-flag	Tell hosts to use the administered (stateful) protocol (i.e. DHCP) for autoconfiguration of other (non-address) information
MTU	link-mtu	Link MTU value placed in RAs, excluded in RAs if unset
Router Lifetime	default-lifetime	Lifetime associated with the default router in units of seconds
Reachable Time	reachable-time	Time, in milliseconds, that a node assumes a neighbor is reachable after having received a reachability confirmation
Retransmit Timer	retrans-timer	Time in milliseconds between retransmitted Neighbor Solicitation messages
Default Router Preference Interval	default-preference interval	Preference associated with the default router Min and max intervals between unsolicited multicast RAs
DNSSL	dnssl	DNS search list to advertise
Name Server	name-server	Advertise DNS server per <a href="https://tools.ietf.org/html/rfc6106">https://tools.ietf.org/html/rfc6106</a>

## Advertising a Prefix

**set service router-advert interface <interface> prefix <prefix/mask>**

**Bemerkung:** You can also opt for using `::/64` as prefix for your RAs. This will take the IPv6 GUA prefix assigned to the interface, which comes in handy when using DHCPv6-PD.

VyOS Field	Description
decrement-lifetime	Lifetime is decremented by the number of seconds since the last RA - use in conjunction with a DHCPv6-PD prefix
deprecate-prefix	Upon shutdown, this option will deprecate the prefix by announcing it in the shutdown RA
no-autonomous-flag	Prefix can not be used for stateless address auto-configuration
no-on-link-flag	Prefix can not be used for on-link determination
preferred-lifetime	Time in seconds that the prefix will remain preferred (default 4 hours)
valid-lifetime	Time in seconds that the prefix will remain valid (default: 30 days)

## Advertising a NAT64 Prefix

**set service router-advert interface <interface> nat64prefix <prefix/mask>**

Enable PREF64 option as outlined in [RFC 8781](#).

NAT64 prefix mask must be one of: /32, /40, /48, /56, /64 or /96.

---

**Bemerkung:** The well known NAT64 prefix is 64:ff9b::/96

---

VyOS Field	Description
valid-lifetime	Time in seconds that the prefix will remain valid (default: 65528 seconds)

## Disabling Advertisements

To disable advertisements without deleting the configuration:

**set service router-advert interface <interface> no-send-advert**

## Example

Your LAN connected on eth0 uses prefix 2001:db8:beef:2::/64 with the router being 2001:db8:beef:2::1

```
set interfaces ethernet eth0 address 2001:db8:beef:2::1/64

set service router-advert interface eth0 default-preference 'high'
set service router-advert interface eth0 name-server '2001:db8::1'
set service router-advert interface eth0 name-server '2001:db8::2'
set service router-advert interface eth0 other-config-flag
set service router-advert interface eth0 prefix 2001:db8:beef:2::/64
```

## 8.10.19 Salt-Minion

[SaltStack](#) is Python-based, open-source software for event-driven IT automation, remote task execution, and configuration management. Supporting the „infrastructure as code“ approach to data center system and network deployment and management, configuration automation, SecOps orchestration, vulnerability remediation, and hybrid cloud control.

## Requirements

To use the Salt-Minion, a running Salt-Master is required. You can find more in the [Salt Project Documentation](#)

## Configuration

**set service salt-minion hash <type>**

The hash type used when discovering file on master server (default: sha256)

**set service salt-minion id <id>**

Explicitly declare ID for this minion to use (default: hostname)

**set service salt-minion interval <1-1440>**

Interval in minutes between updates (default: 60)

**set service salt-minion master <hostname | IP>**

The hostname or IP address of the master

**set service salt-minion master-key <key>**

URL with signature of master for auth reply verification

Please take a look in the Automation section to find some usefull Examples.

### 8.10.20 SNMP

SNMP is an Internet Standard protocol for collecting and organizing information about managed devices on IP networks and for modifying that information to change device behavior. Devices that typically support SNMP include cable modems, routers, switches, servers, workstations, printers, and more.

SNMP is widely used in network management for network monitoring. SNMP exposes management data in the form of variables on the managed systems organized in a management information base (MIB) which describe the system status and configuration. These variables can then be remotely queried (and, in some circumstances, manipulated) by managing applications.

Three significant versions of SNMP have been developed and deployed. SNMPv1 is the original version of the protocol. More recent versions, SNMPv2c and SNMPv3, feature improvements in performance, flexibility and security.

SNMP is a component of the Internet Protocol Suite as defined by the Internet Engineering Task Force (IETF). It consists of a set of standards for network management, including an application layer protocol, a database schema, and a set of data objects.

#### Overview and basic concepts

In typical uses of SNMP, one or more administrative computers called managers have the task of monitoring or managing a group of hosts or devices on a computer network. Each managed system executes a software component called an agent which reports information via SNMP to the manager.

An SNMP-managed network consists of three key components:

- Managed devices
- Agent - software which runs on managed devices
- Network management station (NMS) - software which runs on the manager

A managed device is a network node that implements an SNMP interface that allows unidirectional (read-only) or bidirectional (read and write) access to node-specific information. Managed devices exchange node-specific information with the NMSs. Sometimes called network elements, the managed devices can be any type of device, including, but not limited to, routers, access servers, switches, cable modems, bridges, hubs, IP telephones, IP video cameras, computer hosts, and printers.

An agent is a network-management software module that resides on a managed device. An agent has local knowledge of management information and translates that information to or from an SNMP-specific form.

A network management station executes applications that monitor and control managed devices. NMSs provide the bulk of the processing and memory resources required for network management. One or more NMSs may exist on any managed network.

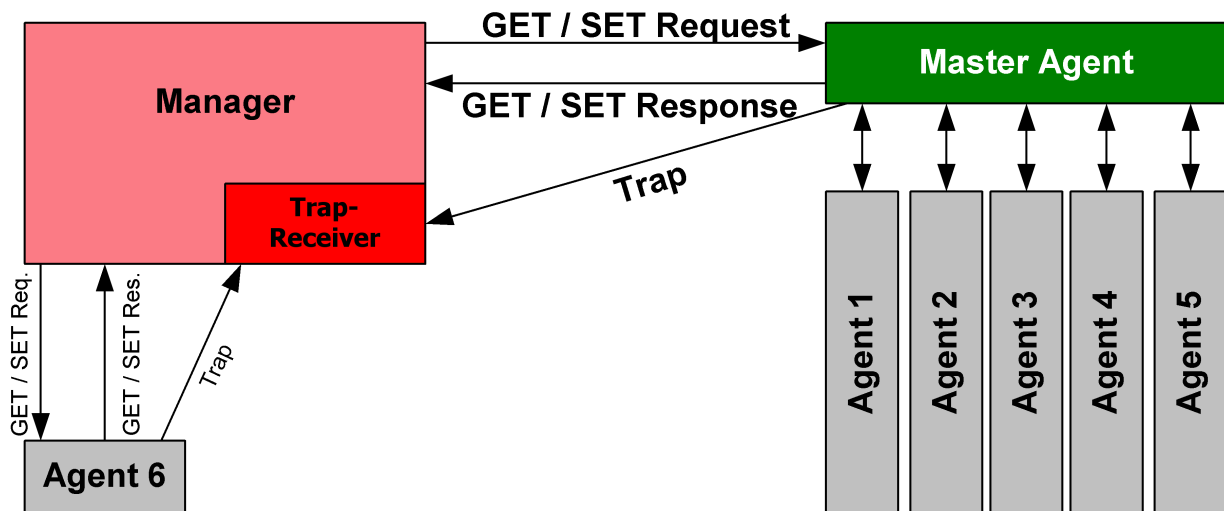

Abb. 5: Image thankfully borrowed from [https://en.wikipedia.org/wiki/File:SNMP\\_communication\\_principles\\_diagram.PNG](https://en.wikipedia.org/wiki/File:SNMP_communication_principles_diagram.PNG) which is under the GNU Free Documentation License

---

**Bemerkung:** VyOS SNMP supports both IPv4 and IPv6.

---

## SNMP Protocol Versions

VyOS itself supports **SNMPv2** (version 2) and **SNMPv3** (version 3) where the later is recommended because of improved security (optional authentication and encryption).

### SNMPv2

SNMPv2 is the original and most commonly used version. For authorizing clients, SNMP uses the concept of communities. Communities may have authorization set to read only (this is most common) or to read and write (this option is not actively used in VyOS).

SNMP can work synchronously or asynchronously. In synchronous communication, the monitoring system queries the router periodically. In asynchronous, the router sends notification to the „trap“ (the monitoring host).

SNMPv2 does not support any authentication mechanisms, other than client source address, so you should specify addresses of clients allowed to monitor the router. Note that SNMPv2 also supports no encryption and always sends data in plain text.

## Example

```
# Define a community
set service snmp community routers authorization ro

# Allow monitoring access from the entire network
set service snmp community routers network 192.0.2.0/24
set service snmp community routers network 2001::db8:ffff:eeee::/64

# Allow monitoring access from specific addresses
set service snmp community routers client 203.0.113.10
set service snmp community routers client 203.0.113.20

# Define optional router information
set service snmp location "UK, London"
set service snmp contact "admin@example.com"

# Trap target if you want asynchronous communication
set service snmp trap-target 203.0.113.10

# Listen only on specific IP addresses (port defaults to 161)
set service snmp listen-address 172.16.254.36 port 161
set service snmp listen-address 2001::db8::f00::1
```

## SNMPv3

SNMPv3 (version 3 of the SNMP protocol) introduced a whole slew of new security related features that have been missing from the previous versions. Security was one of the biggest weakness of SNMP until v3. Authentication in SNMP Versions 1 and 2 amounts to nothing more than a password (community string) sent in clear text between a manager and agent. Each SNMPv3 message contains security parameters which are encoded as an octet string. The meaning of these security parameters depends on the security model being used.

The security approach in SNMPv3 targets:

- Confidentiality – Encryption of packets to prevent snooping by an unauthorized source.
- Integrity – Message integrity to ensure that a packet has not been tampered while in transit including an optional packet replay protection mechanism.
- Authentication – to verify that the message is from a valid source.

## Example

- Let SNMP daemon listen only on IP address 192.0.2.1
- Configure new SNMP user named „vyos“ with password „vyos12345678“
- New user will use SHA/AES for authentication and privacy

```
set service snmp listen-address 192.0.2.1
set service snmp location 'VyOS Datacenter'
set service snmp v3 engineid '000000000000000000000002'
set service snmp v3 group default mode 'ro'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set service snmp v3 group default view 'default'
set service snmp v3 user vyos auth plaintext-password 'vyos12345678'
set service snmp v3 user vyos auth type 'sha'
set service snmp v3 user vyos group 'default'
set service snmp v3 user vyos privacy plaintext-password 'vyos12345678'
set service snmp v3 user vyos privacy type 'aes'
set service snmp v3 view default oid 1

```

After commit the plaintext passwords will be hashed and stored in your configuration. The resulting CLI config will look like:

```

vyos@vyos# show service snmp
listen-address 192.0.2.1 {
}
location "VyOS Datacenter"
v3 {
  engineid 00000000000000000000000002
  group default {
    mode ro
    view default
  }
  user vyos {
    auth {
      encrypted-password 4e52fe55fd011c9c51ae2c65f4b78ca93dcafdfe
      type sha
    }
    group default
    privacy {
      encrypted-password 4e52fe55fd011c9c51ae2c65f4b78ca93dcafdfe
      type aes
    }
  }
  view default {
    oid 1 {
    }
  }
}

```

You can test the SNMPv3 functionality from any linux based system, just run the following command: `snmpwalk -v 3 -u vyos -a SHA -A vyos12345678 -x AES -X vyos12345678 -l authPriv 192.0.2.1 .1`

## VyOS MIBs

All SNMP MIBs are located in each image of VyOS here: `/usr/share/snmp/mibs/`

You are be able to download the files using SCP, once the SSH service has been activated like so

```
scp -r vyos@your_router:/usr/share/snmp/mibs /your_folder/mibs
```

## SNMP Extensions

To extend SNMP agent functionality, custom scripts can be executed every time the agent is being called. This can be achieved by using arbitrary extension commands. The first step is to create a functional script of course, then upload it to your VyOS instance via the command `scp your_script.sh vyos@your_router:/config/user-data`. Once the script is uploaded, it needs to be configured via the command below.

```
set service snmp script-extensions extension-name my-extension script your_script.sh
commit
```

The OID `.1.3.6.1.4.1.8072.1.3.2.3.1.1.4.116.101.115.116`, once called, will contain the output of the extension.

```
root@vyos:/home/vyos# snmpwalk -v2c -c public 127.0.0.1 nsExtendOutput1
NET-SNMP-EXTEND-MIB::nsExtendOutputLine."my-extension" = STRING: hello
NET-SNMP-EXTEND-MIB::nsExtendOutputFull."my-extension" = STRING: hello
NET-SNMP-EXTEND-MIB::nsExtendOutNumLines."my-extension" = INTEGER: 1
NET-SNMP-EXTEND-MIB::nsExtendResult."my-extension" = INTEGER: 0
```

## SolarWinds

If you happen to use SolarWinds Orion as NMS you can also use the Device Templates Management. A template for VyOS can be easily imported.

Create a file named `VyOS-1.3.6.1.4.1.44641.ConfigMgmt-Commands` using the following content:

```
<Configuration-Management Device="VyOS" SystemOID="1.3.6.1.4.1.44641">
  <Commands>
    <Command Name="Reset" Value="set terminal width 0${CRLF}set terminal length 0"/>
    <Command Name="Reboot" Value="reboot${CRLF}Yes"/>
    <Command Name="EnterConfigMode" Value="configure"/>
    <Command Name="ExitConfigMode" Value="commit${CRLF}exit"/>
    <Command Name="DownloadConfig" Value="show configuration commands"/>
    <Command Name="SaveConfig" Value="commit${CRLF}save"/>
    <Command Name="Version" Value="show version"/>
    <Command Name="MenuBased" Value="False"/>
    <Command Name="VirtualPrompt" Value=":~/>
  </Commands>
</Configuration-Management>
```

### 8.10.21 SSH

SSH (Secure Shell) is a cryptographic network protocol for operating network services securely over an unsecured network. The standard TCP port for SSH is 22. The best known example application is for remote login to computer systems by users.

SSH provides a secure channel over an unsecured network in a client-server architecture, connecting an SSH client application with an SSH server. Common applications include remote command-line login and remote command execution, but any network service can be secured with SSH. The protocol specification distinguishes between two major versions, referred to as SSH-1 and SSH-2.

The most visible application of the protocol is for access to shell accounts on Unix-like operating systems, but it sees some limited use on Windows as well. In 2015, Microsoft announced that they would include native support for SSH in a future release.

SSH was designed as a replacement for Telnet and for unsecured remote shell protocols such as the Berkeley rlogin, rsh, and rexec protocols. Those protocols send information, notably passwords, in plaintext, rendering them susceptible to interception and disclosure using packet analysis. The encryption used by SSH is intended to provide confidentiality and integrity of data over an unsecured network, such as the Internet.

---

**Bemerkung:** VyOS 1.1 supported login as user `root`. This has been removed due to tighter security in VyOS 1.2.

---

**Siehe auch:**

SSH *Key Based Authentication*

## Configuration

**set service ssh port <port>**

Enabling SSH only requires you to specify the port <port> you want SSH to listen on. By default, SSH runs on port 22.

**set service ssh listen-address <address>**

Specify IPv4/IPv6 listen address of SSH server. Multiple addresses can be defined.

**set service ssh ciphers <cipher>**

Define allowed ciphers used for the SSH connection. A number of allowed ciphers can be specified, use multiple occurrences to allow multiple ciphers.

List of supported ciphers: 3des-cbc, aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, aes256-ctr, arcfour128, arcfour256, arcfour, blowfish-cbc, cast128-cbc

**set service ssh disable-password-authentication**

Disable password based authentication. Login via SSH keys only. This hardens security!

**set service ssh disable-host-validation**

Disable the host validation through reverse DNS lookups - can speedup login time when reverse lookup is not possible.

**set service ssh macs <mac>**

Specifies the available MAC algorithms. The MAC algorithm is used in protocol version 2 for data integrity protection. Multiple algorithms can be provided.

List of supported MACs: hmac-md5, hmac-md5-96, hmac-ripemd160, hmac-sha1, hmac-sha1-96, hmac-sha2-256, hmac-sha2-512, umac-64@openssh.com, umac-128@openssh.com, hmac-md5-etm@openssh.com, hmac-md5-96-etm@openssh.com, hmac-ripemd160-etm@openssh.com, hmac-sha1-etm@openssh.com, hmac-sha1-96-etm@openssh.com, hmac-sha2-256-etm@openssh.com, hmac-sha2-512-etm@openssh.com, umac-64-etm@openssh.com, umac-128-etm@openssh.com

**set service ssh access-control <allow | deny> <group | user> <name>**

Add access-control directive to allow or deny users and groups. Directives are processed in the following order of precedence: deny-users, allow-users, deny-groups and allow-groups.

**set service ssh client-keepalive-interval <interval>**

Specify timeout interval for keepalive message in seconds.

**set service ssh key-exchange <kex>**

Specify allowed KEX (Key Exchange) algorithms.

List of supported algorithms: diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, diffie-hellman-group14-sha256, diffie-hellman-group16-sha512, diffie-hellman-group18-sha512, diffie-hellman-group-exchange-sha1, diffie-hellman-group-exchange-sha256, ecdh-sha2-nistp256, ecdh-sha2-nistp384, ecdh-sha2-nistp521, curve25519-sha256 and curve25519-sha256@libssh.org.

**set service ssh loglevel <quiet | fatal | error | info | verbose>**

Set the sshd log level. The default is info.

**set service ssh vrf <name>**

Specify name of the VRF instance.

## Dynamic-protection

Protects host from brute-force attacks against SSH. Log messages are parsed, line-by-line, for recognized patterns. If an attack, such as several login failures within a few seconds, is detected, the offending IP is blocked. Offenders are unblocked after a set interval.

**set service ssh dynamic-protection**

Allow ssh dynamic-protection.

**set service ssh dynamic-protection allow-from <address | prefix>**

Whitelist of addresses and networks. Always allow inbound connections from these systems.

**set service ssh dynamic-protection block-time <sec>**

Block source IP in seconds. Subsequent blocks increase by a factor of 1.5 The default is 120.

**set service ssh dynamic-protection detect-time <sec>**

Remember source IP in seconds before reset their score. The default is 1800.

**set service ssh dynamic-protection threshold <sec>**

Block source IP when their cumulative attack score exceeds threshold. The default is 30.

## Operation

**restart ssh**

Restart the SSH daemon process, the current session is not affected, only the background daemon is restarted.

**generate ssh server-key**

Re-generated the public/private keyportion which SSH uses to secure connections.

---

**Bemerkung:** Already learned known\_hosts files of clients need an update as the public key will change.

---

**generate ssh client-key /path/to/private\_key**

Re-generated a known pub/private keyfile which can be used to connect to other services (e.g. RPKI cache).

Example:

```
vyos@vyos:~$ generate ssh client-key /config/auth/id_rsa_rpki
Generating public/private rsa key pair.
Your identification has been saved in /config/auth/id_rsa_rpki.
Your public key has been saved in /config/auth/id_rsa_rpki.pub.
The key fingerprint is:
SHA256:XGv2PpdOzVCzpmEzJZga8hTRq7B/ZYL3fXaiolFLS5Q vyos@vyos
The key's randomart image is:
+---[RSA 2048]-----+
|      oo      |
|      ..o     |
|    . o.o.. o. |
|    o+ooo  o.o |
|    Eo*   =.o  |
|    o = +.o*+  |
|    = o *.o.o  |
|    o * +.o+.+ |
|    =.. o=.oo  |
+-----[SHA256]-----+
```

Two new files `/config/auth/id_rsa_rpki` and `/config/auth/id_rsa_rpki.pub` will be created.

#### **generate public-key-command user <username> path <location>**

Generate the configuration mode commands to add a public key for *Key Based Authentication*.  
 <location> can be a local path or a URL pointing at a remote file.

Supported remote protocols are FTP, FTPS, HTTP, HTTPS, SCP/SFTP and TFTP.

Example:

```
alyssa@vyos:~$ generate public-key-command user alyssa path sftp://example.net/home/
↪ alyssa/.ssh/id_rsa.pub
# To add this key as an embedded key, run the following commands:
configure
set system login user alyssa authentication public-keys alyssa@example.net key AAA..
↪ .
set system login user alyssa authentication public-keys alyssa@example.net type ssh-
↪ rsa
commit
save
exit

ben@vyos:~$ generate public-key-command user ben path ~/.ssh/id_rsa.pub
# To add this key as an embedded key, run the following commands:
configure
set system login user ben authentication public-keys ben@vyos key AAA...
set system login user ben authentication public-keys ben@vyos type ssh-dss
commit
save
exit
```

#### **show log ssh**

Show SSH server log.

#### **monitor log ssh**

Follow the SSH server log.

**show log ssh dynamic-protection**

Show SSH dynamic-protection log.

**monitor log ssh dynamic-protection**

Follow the SSH dynamic-protection log.

**show ssh dynamic-protection**

Show list of IPs currently blocked by SSH dynamic-protection.

**show ssh fingerprints**

Show SSH server public key fingerprints.

**show ssh fingerprints ascii**

Show SSH server public key fingerprints, including a visual ASCII art representation.

## 8.10.22 TFTP Server

TFTP (Trivial File Transfer Protocol) is a simple, lockstep file transfer protocol which allows a client to get a file from or put a file onto a remote host. One of its primary uses is in the early stages of nodes booting from a local area network. TFTP has been used for this application because it is very simple to implement.

### Configuration

**set service tftp-server directory <directory>**

Enable TFTP service by specifying the <directory> which will be used to serve files.

---

**Hinweis:** Choose your directory location carefully or you will lose the content on image upgrades. Any directory under /config is saved at this will be migrated.

---

**set service tftp-server listen-address <address>**

Configure the IPv4 or IPv6 listen address of the TFTP server. Multiple IPv4 and IPv6 addresses can be given. There will be one TFTP server instance listening on each IP address.

**set service tftp-server listen-address <address> vrf <name>**

Additional option to run TFTP server in the VRF context

---

**Bemerkung:** Configuring a listen-address is essential for the service to work.

---

**set service tftp-server allow-upload**

Optional, if you want to enable uploads, else TFTP server will act as a read-only server.

## Example

Provide TFTP server listening on both IPv4 and IPv6 addresses 192.0.2.1 and 2001:db8::1 serving the content from /config/tftpboot. Uploading via TFTP to this server is disabled.

The resulting configuration will look like:

```
vyos@vyos# show service
tftp-server {
    directory /config/tftpboot
    listen-address 2001:db8::1
    listen-address 192.0.2.1
}
```

## Verification

Client:

```
vyos@RTR2:~$ tftp -p -l /config/config.boot -r backup 192.0.2.1
backup1          100% |*****|          723  0:00:00 ETA
```

Server:

```
vyos@RTR1# ls -ltr /config/tftpboot/
total 1
-rw-rw-rw- 1 tftp tftp  1995 May 19 16:02 backup
```

## 8.10.23 Webproxy

The proxy service in VyOS is based on [Squid](#) and some related modules.

[Squid](#) is a caching and forwarding HTTP web proxy. It has a wide variety of uses, including speeding up a web server by caching repeated requests, caching web, DNS and other computer network lookups for a group of people sharing network resources, and aiding security by filtering traffic. Although primarily used for HTTP and FTP, Squid includes limited support for several other protocols including Internet Gopher, SSL,[6] TLS and HTTPS. Squid does not support the SOCKS protocol.

URL Filtering is provided by [SquidGuard](#).

## Configuration

**set service webproxy append-domain <domain>**

Use this command to specify a domain name to be appended to domain-names within URLs that do not include a dot . the domain is appended.

Example: to be appended is set to vyos.net and the URL received is `www/foo.html`, the system will use the generated, final URL of `www.vyos.net/foo.html`.

```
set service webproxy append-domain vyos.net
```

**set service webproxy cache-size <size>**

The size of the on-disk Proxy cache is user configurable. The Proxies default cache-size is configured to 100 MB.

Unit of this command is MB.

```
set service webproxy cache-size 1024
```

#### **set service webproxy default-port <port>**

Specify the port used on which the proxy service is listening for requests. This port is the default port used for the specified listen-address.

Default port is 3128.

```
set service webproxy default-port 8080
```

#### **set service webproxy domain-block <domain>**

Used to block specific domains by the Proxy. Specifying „vyos.net“ will block all access to vyos.net, and specifying „.xxx“ will block all access to URLs having an URL ending on .xxx.

```
set service webproxy domain-block vyos.net
```

#### **set service webproxy domain-noncache <domain>**

Allow access to sites in a domain without retrieving them from the Proxy cache. Specifying „vyos.net“ will allow access to vyos.net but the pages accessed will not be cached. It useful for working around problems with „If-Modified-Since“ checking at certain sites.

```
set service webproxy domain-noncache vyos.net
```

#### **set service webproxy listen-address <address>**

Specifies proxy service listening address. The listen address is the IP address on which the web proxy service listens for client requests.

For security, the listen address should only be used on internal/trusted networks!

```
set service webproxy listen-address 192.0.2.1
```

#### **set service webproxy listen-address <address> disable-transparent**

Disables web proxy transparent mode at a listening address.

In transparent proxy mode, all traffic arriving on port 80 and destined for the Internet is automatically forwarded through the proxy. This allows immediate proxy forwarding without configuring client browsers.

Non-transparent proxying requires that the client browsers be configured with the proxy settings before requests are redirected. The advantage of this is that the client web browser can detect that a proxy is in use and can behave accordingly. In addition, web-transmitted malware can sometimes be blocked by a non-transparent web proxy, since they are not aware of the proxy settings.

```
set service webproxy listen-address 192.0.2.1 disable-transparent
```

#### **set service webproxy listen-address <address> port <port>**

Sets the listening port for a listening address. This overrides the default port of 3128 on the specific listen address.

```
set service webproxy listen-address 192.0.2.1 port 8080
```

#### **set service webproxy reply-block-mime <mime>**

Used to block a specific mime-type.

```
# block all PDFs
set service webproxy reply-block-mime application/pdf
```

#### **set service webproxy reply-body-max-size <size>**

Specifies the maximum size of a reply body in KB, used to limit the reply size.

All reply sizes are accepted by default.

```
set service webproxy reply-body-max-size 2048
```

#### **set service webproxy safe-ports <port>**

Add new port to Safe-ports acl. Ports included by default in Safe-ports acl: 21, 70, 80, 210, 280, 443, 488, 591, 777, 873, 1025-65535

#### **set service webproxy ssl-safe-ports <port>**

Add new port to SSL-ports acl. Ports included by default in SSL-ports acl: 443

### **Authentication**

The embedded Squid proxy can use LDAP to authenticate users against a company wide directory. The following configuration is an example of how to use Active Directory as authentication backend. Queries are done via LDAP.

#### **set service webproxy authentication children <number>**

Maximum number of authenticator processes to spawn. If you start too few Squid will have to wait for them to process a backlog of credential verifications, slowing it down. When password verifications are done via a (slow) network you are likely to need lots of authenticator processes.

This defaults to 5.

```
set service webproxy authentication children 10
```

#### **set service webproxy authentication credentials-ttl <time>**

Specifies how long squid assumes an externally validated username:password pair is valid for - in other words how often the helper program is called for that user. Set this low to force revalidation with short lived passwords.

Time is in minutes and defaults to 60.

```
set service webproxy authentication credentials-ttl 120
```

#### **set service webproxy authentication method <ldap>**

Proxy authentication method, currently only LDAP is supported.

```
set service webproxy authentication method ldap
```

#### **set service webproxy authentication realm**

Specifies the protection scope (aka realm name) which is to be reported to the client for the authentication scheme. It is commonly part of the text the user will see when prompted for their username and password.

```
set service webproxy authentication realm "VyOS proxy auth"
```

## LDAP

**set service webproxy authentication ldap base-dn <base-dn>**

Specifies the base DN under which the users are located.

```
set service webproxy authentication ldap base-dn DC=vyos,DC=net
```

**set service webproxy authentication ldap bind-dn <bind-dn>**

The DN and password to bind as while performing searches.

```
set service webproxy authentication ldap bind-dn CN=proxyuser,CN=Users,DC=vyos,  
↪DC=net
```

**set service webproxy authentication ldap filter-expression <expr>**

LDAP search filter to locate the user DN. Required if the users are in a hierarchy below the base DN, or if the login name is not what builds the user specific part of the users DN.

The search filter can contain up to 15 occurrences of %s which will be replaced by the username, as in „uid=%s“ for [RFC 2037](#) directories. For a detailed description of LDAP search filter syntax see [RFC 2254](#).

```
set service webproxy authentication ldap filter-expression (cn=%s)
```

**set service webproxy authentication ldap password <password>**

The DN and password to bind as while performing searches. As the password needs to be printed in plain text in your Squid configuration it is strongly recommended to use a account with minimal associated privileges. This to limit the damage in case someone could get hold of a copy of your Squid configuration file.

```
set service webproxy authentication ldap password vyos
```

**set service webproxy authentication ldap persistent-connection**

Use a persistent LDAP connection. Normally the LDAP connection is only open while validating a username to preserve resources at the LDAP server. This option causes the LDAP connection to be kept open, allowing it to be reused for further user validations.

Recommended for larger installations.

```
set service webproxy authentication ldap persistent-connection
```

**set service webproxy authentication ldap port <port>**

Specify an alternate TCP port where the ldap server is listening if other than the default LDAP port 389.

```
set service webproxy authentication ldap port 389
```

**set service webproxy authentication ldap server <server>**

Specify the LDAP server to connect to.

```
set service webproxy authentication ldap server ldap.vyos.net
```

**set service webproxy authentication ldap use-ssl**

Use TLS encryption.

```
set service webproxy authentication ldap use-ssl
```

### **set service webproxy authentication ldap username-attribute <attr>**

Specifies the name of the DN attribute that contains the username/login. Combined with the base DN to construct the users DN when no search filter is specified (*filter-expression*).

Defaults to ,uid‘

---

**Bemerkung:** This can only be done if all your users are located directly under the same position in the LDAP tree and the login name is used for naming each user object. If your LDAP tree does not match these criterias or if you want to filter who are valid users then you need to use a search filter to search for your users DN (*filter-expression*).

---

```
set service webproxy authentication ldap username-attribute uid
```

### **set service webproxy authentication ldap version <2 | 3>**

LDAP protocol version. Defaults to 3 if not specified.

```
set service webproxy authentication ldap version 2
```

## **URL filtering**

### **set service webproxy url-filtering disable**

Disables web filtering without discarding configuration.

```
set service webproxy url-filtering disable
```

## **Operation**

### **Filtering**

### **Update**

If you want to use existing blacklists you have to create/download a database first. Otherwise you will not be able to commit the config changes.

### **update webproxy blacklists**

Download/Update complete blacklist

```
vyos@vyos:~$ update webproxy blacklists
Warning: No url-filtering blacklist installed
Would you like to download a default blacklist? [confirm][y]
Connecting to ftp.univ-tlse1.fr (193.49.48.249:21)

Building DB for [arjel/domains] - 69 entries
...

Building DB for [webmail/domains] - 374 entries
Building DB for [webmail/urls] - 9 entries

The webproxy daemon must be restarted
Would you like to restart it now? [confirm][y]

[ ok ] Restarting squid (via systemctl): squid.service.
vyos@vyos:~$

```

**update webproxy blacklists category <category>**

Download/Update partial blacklist.

Use tab completion to get a list of categories.

- To auto update the blacklist files
 

```
set service webproxy url-filtering squidguard auto-update update-hour 23
```
- To configure blocking add the following to the configuration
 

```
set service webproxy url-filtering squidguard block-category ads
set service webproxy url-filtering squidguard block-category malware
```

**Bypassing the webproxy**

Some services don't work correctly when being handled via a web proxy. So sometimes it is useful to bypass a transparent proxy:

- To bypass the proxy for every request that is directed to a specific destination:
 

```
set service webproxy whitelist destination-address 198.51.100.33
set service webproxy whitelist destination-address 192.0.2.0/24
```
- To bypass the proxy for every request that is coming from a specific source:
 

```
set service webproxy whitelist source-address 192.168.1.2
set service webproxy whitelist source-address 192.168.2.0/24
```

(This can be useful when a called service has many and/or often changing destination addresses - e.g. Netflix.)

## Examples

```
vyos@vyos# show service webproxy
authentication {
  children 5
  credentials-ttl 60
  ldap {
    base-dn DC=example,DC=local
    bind-dn CN=proxyuser,CN=Users,DC=example,DC=local
    filter-expression (cn=%s)
    password Qwert1234
    server ldap.example.local
    username-attribute cn
  }
  method ldap
  realm "VyOS Webproxy"
}
cache-size 100
default-port 3128
listen-address 192.168.188.103 {
  disable-transparent
}
```

## 8.11 System

### 8.11.1 Acceleration

In this command tree, all hardware acceleration options will be handled. At the moment only [Intel® QAT](#) is supported

#### Intel® QAT

##### show system acceleration qat

use this command to check if there is an Intel® QAT supported Processor in your system.

```
vyos@vyos:~$ show system acceleration qat
01:00.0 Co-processor [0b40]: Intel Corporation Atom Processor C3000 Series
↳ QuickAssist Technology [8086:19e2] (rev 11)
```

if there is non device the command will show `No QAT device found`

##### set system acceleration qat

if there is a supported device, enable Intel® QAT

##### show system acceleration qat status

Check if the Intel® QAT device is up and ready to do the job.

```
vyos@vyos:~$ show system acceleration qat status
Checking status of all devices.
There is 1 QAT acceleration device(s) in the system:
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
qat_dev0 - type: c3xxx, inst_id: 0, node_id: 0, bsf: 0000:01:00.0, #accel: 3
→#engines: 6 state: up
```

## Operation Mode

**show system acceleration qat device <device> config**

Show the full config uploaded to the QAT device.

**show system acceleration qat device <device> flows**

Get an overview over the encryption counters.

**show system acceleration qat interrupts**

Show binded qat device interrupts to certain core.

## Example

Let's build a simple VPN between 2 Intel® QAT ready devices.

Side A:

```
set interfaces vti vti1 address '192.168.1.2/24'
set vpn ipsec authentication psk right id '10.10.10.2'
set vpn ipsec authentication psk right id '10.10.10.1'
set vpn ipsec authentication psk right secret 'Qwerty123'
set vpn ipsec esp-group MyESPGroup proposal 1 encryption 'aes256'
set vpn ipsec esp-group MyESPGroup proposal 1 hash 'sha256'
set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group '14'
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption 'aes256'
set vpn ipsec ike-group MyIKEGroup proposal 1 hash 'sha256'
set vpn ipsec interface 'eth0'
set vpn ipsec site-to-site peer right authentication local-id '10.10.10.2'
set vpn ipsec site-to-site peer right authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer right authentication remote-id '10.10.10.1'
set vpn ipsec site-to-site peer right connection-type 'initiate'
set vpn ipsec site-to-site peer right default-esp-group 'MyESPGroup'
set vpn ipsec site-to-site peer right ike-group 'MyIKEGroup'
set vpn ipsec site-to-site peer right local-address '10.10.10.2'
set vpn ipsec site-to-site peer right remote-address '10.10.10.1'
set vpn ipsec site-to-site peer right vti bind 'vti1'
```

Side B:

```
set interfaces vti vti1 address '192.168.1.1/24'
set vpn ipsec authentication psk left id '10.10.10.2'
set vpn ipsec authentication psk left id '10.10.10.1'
set vpn ipsec authentication psk left secret 'Qwerty123'
set vpn ipsec esp-group MyESPGroup proposal 1 encryption 'aes256'
set vpn ipsec esp-group MyESPGroup proposal 1 hash 'sha256'
set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group '14'
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption 'aes256'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set vpn ipsec ike-group MyIKEGroup proposal 1 hash 'sha256'
set vpn ipsec interface 'eth0'
set vpn ipsec site-to-site peer left authentication local-id '10.10.10.1'
set vpn ipsec site-to-site peer left authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer left authentication remote-id '10.10.10.2'
set vpn ipsec site-to-site peer left connection-type 'initiate'
set vpn ipsec site-to-site peer left default-esp-group 'MyESPGroup'
set vpn ipsec site-to-site peer left ike-group 'MyIKEGroup'
set vpn ipsec site-to-site peer left local-address '10.10.10.1'
set vpn ipsec site-to-site peer left remote-address '10.10.10.2'
set vpn ipsec site-to-site peer left vti bind 'vti1'
```

a bandwidth test over the VPN got these results:

```
Connecting to host 192.168.1.2, port 5201
[ 9] local 192.168.1.1 port 51344 connected to 192.168.1.2 port 5201
[ ID] Interval          Transfer      Bitrate      Retr  Cwnd
[ 9]  0.00-1.01    sec   32.3 MBytes  268 Mbits/sec    0   196 KBytes
[ 9]  1.01-2.03    sec   32.5 MBytes  268 Mbits/sec    0   208 KBytes

```

### 8.11.2 Conntrack

VyOS can be configured to track connections using the connection tracking subsystem. Connection tracking becomes operational once either stateful firewall or NAT is configured.

#### Configure

**set system conntrack table-size <1-50000000>** default: 262144

The connection tracking table contains one entry for each connection being tracked by the system.

**set system conntrack expect-table-size <1-50000000>** default: 2048

The connection tracking expect table contains one entry for each expected connection related to an existing connection. These are generally used by “connection tracking helper” modules such as FTP. The default size of the expect table is 2048 entries.

**set system conntrack hash-size <1-50000000>** default: 32768

Set the size of the hash table. The connection tracking hash table makes searching the connection tracking table faster. The hash table uses “buckets” to record entries in the connection tracking table.

**set system conntrack modules ftp**

**set system conntrack modules h323**

**set system conntrack modules nfs**

**set system conntrack modules pptp**

**set system conntrack modules sip**

**set system conntrack modules sqlnet**

**set system conntrack modules tftp**

Configure the connection tracking protocol helper modules. All modules are enable by default.

Use *delete system conntrack modules* to deactivate all modules.

Or, for example ftp, *delete system conntrack modules ftp*.

**set system conntrack tcp half-open-connections <1-21474836>** default: 512

Set the maximum number of TCP half-open connections.

**set system conntrack tcp loose <enable | disable>** default: enable

Policy to track previously established connections.

**set system conntrack tcp max-retrans <1-2147483647>** default: 3

Set the number of TCP maximum retransmit attempts.

## Conntrack Timeouts

VyOS supports setting timeouts for connections according to the connection type. You can set timeout values for generic connections, for ICMP connections, UDP connections, or for TCP connections in a number of different states.

```
set system conntrack timeout icmp <1-21474836> default: 30
set system conntrack timeout other <1-21474836> default: 600
set system conntrack timeout tcp close <1-21474836> default: 10
set system conntrack timeout tcp close-wait <1-21474836> default: 60
set system conntrack timeout tcp established <1-21474836> default: 432000
set system conntrack timeout tcp fin-wait <1-21474836> default: 120
set system conntrack timeout tcp last-ack <1-21474836> default: 30
set system conntrack timeout tcp syn-recv <1-21474836> default: 60
set system conntrack timeout tcp syn-sent <1-21474836> default: 120
set system conntrack timeout tcp time-wait <1-21474836> default: 120
set system conntrack timeout udp other <1-21474836> default: 30
set system conntrack timeout udp stream <1-21474836> default: 180
```

Set the timeout in seconds for a protocol or state.

You can also define custom timeout values to apply to a specific subset of connections, based on a packet and flow selector. To do this, you need to create a rule defining the packet and flow selector.

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> description <test>
```

Set a rule description.

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> destination address
<ip-address>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> source address
<ip-address>
```

Set a destination and/or source address. Accepted input for ipv4:

```
set system conntrack timeout custom ipv4 rule <1-999999> [source | ↵
↵destination] address
Possible completions:
<x.x.x.x>          IPv4 address to match
<x.x.x.x/x>        IPv4 prefix to match
<x.x.x.x>-<x.x.x.x> IPv4 address range to match
!<x.x.x.x>         Match everything except the specified address
!<x.x.x.x/x>       Match everything except the specified prefix
!<x.x.x.x>-<x.x.x.x> Match everything except the specified range

set system conntrack timeout custom ipv6 rule <1-999999> [source | ↵
↵destination] address
Possible completions:
<h:h:h:h:h:h:h>   IP address to match
<h:h:h:h:h:h:h/x> Subnet to match
<h:h:h:h:h:h:h>-<h:h:h:h:h:h:h>
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

	IP range to match
!<h:h:h:h:h:h:h>	Match everything except the specified address
!<h:h:h:h:h:h:h/x>	Match everything except the specified prefix
!<h:h:h:h:h:h:h>-<h:h:h:h:h:h:h>	Match everything except the specified range

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> destination port <value>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> source port <value>
```

Set a destination and/or source port. Accepted input:

<port name>	Named port (any name in /etc/services, e.g., http)
<1-65535>	Numbered port
<start>-<end>	Numbered port range (e.g., 1001-1005)

Multiple destination ports can be specified as a comma-separated list. The whole list can also be „negated“ using `!`. For example: `!22,telnet,http,123,1001-1005`

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol tcp close <1-21474836>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol tcp close-wait <1-21474836>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol tcp established <1-21474836>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol tcp fin-wait <1-21474836>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol tcp last-ack <1-21474836>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol tcp syn-recv <1-21474836>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol tcp syn-sent <1-21474836>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol tcp time-wait <1-21474836>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol udp replied <1-21474836>
```

```
set system conntrack timeout custom [ipv4 | ipv6] rule <1-999999> protocol udp unreplied <1-21474836>
```

Set the timeout in seconds for a protocol or state in a custom rule.

## Conntrack ignore rules

Customized ignore rules, based on a packet and flow selector.

```
set system conntrack ignore [ipv4 | ipv6] rule <1-999999> description <text>
set system conntrack ignore [ipv4 | ipv6] rule <1-999999> destination address
<ip-address>
set system conntrack ignore [ipv4 | ipv6] rule <1-999999> destination port <port>
set system conntrack ignore [ipv4 | ipv6] rule <1-999999> inbound-interface <interface>
set system conntrack ignore [ipv4 | ipv6] rule <1-999999> protocol <protocol>
set system conntrack ignore [ipv4 | ipv6] rule <1-999999> source address <ip-address>
set system conntrack ignore [ipv4 | ipv6] rule <1-999999> source port <port>
set system conntrack ignore [ipv4 | ipv6] rule <1-999999> tcp flags [not] <text>
```

Allowed values for TCP flags: ack, cwr, ecn, fin, psh, rst, syn and urg. Multiple values are supported, and for inverted selection use not, as shown in the example.

## Conntrack log

```
set system conntrack log icmp destroy
set system conntrack log icmp new
set system conntrack log icmp update
set system conntrack log other destroy
set system conntrack log other new
set system conntrack log other update
set system conntrack log tcp destroy
set system conntrack log tcp new
set system conntrack log tcp update close-wait
set system conntrack log tcp update established
set system conntrack log tcp update fin-wait
set system conntrack log tcp update last-ack
set system conntrack log tcp update syn-received
set system conntrack log tcp update time-wait
set system conntrack log udp destroy
set system conntrack log udp new
set system conntrack log udp update
```

Log the connection tracking events per protocol.

### 8.11.3 Serial Console

For the average user a serial console has no advantage over a console offered by a directly attached keyboard and screen. Serial consoles are much slower, taking up to a second to fill a 80 column by 24 line screen. Serial consoles generally only support non-proportional ASCII text, with limited support for languages other than English.

There are some scenarios where serial consoles are useful. System administration of remote computers is usually done using [SSH](#), but there are times when access to the console is the only way to diagnose and correct software failures. Major upgrades to the installed distribution may also require console access.

#### **set system console device <device>**

Defines the specified device as a system console. Available console devices can be (see completion helper):

- `ttySN` - Serial device name
- `ttyUSBX` - USB Serial device name
- `hvc0` - Xen console

#### **set system console device <device> speed <speed>**

The speed (baudrate) of the console device. Supported values are:

- `1200` - 1200 bps
- `2400` - 2400 bps
- `4800` - 4800 bps
- `9600` - 9600 bps
- `19200` - 19,200 bps
- `38400` - 38,400 bps (default for Xen console)
- `57600` - 57,600 bps
- `115200` - 115,200 bps (default for serial console)

---

**Bemerkung:** If you use USB to serial converters for connecting to your VyOS appliance please note that most of them use software emulation without flow control. This means you should start with a common baud rate (most likely 9600 baud) as otherwise you probably can not connect to the device using high speed baud rates as your serial converter simply can not process this data rate.

---

### 8.11.4 Flow Accounting

VyOS supports flow-accounting for both IPv4 and IPv6 traffic. The system acts as a flow exporter, and you are free to use it with any compatible collector.

Flows can be exported via two different protocols: NetFlow (versions 5, 9 and 10/IPFIX) and sFlow. Additionally, you may save flows to an in-memory table internally in a router.

**Warnung:** You need to disable the in-memory table in production environments! Using IMT (In-Memory Table) may lead to heavy CPU overloading and unstable flow-accounting behavior.

## NetFlow / IPFIX

NetFlow is a feature that was introduced on Cisco routers around 1996 that provides the ability to collect IP network traffic as it enters or exits an interface. By analyzing the data provided by NetFlow, a network administrator can determine things such as the source and destination of traffic, class of service, and the causes of congestion. A typical flow monitoring setup (using NetFlow) consists of three main components:

- **exporter:** aggregates packets into flows and exports flow records towards one or more flow collectors
- **collector:** responsible for reception, storage and pre-processing of flow data received from a flow exporter
- **application:** analyzes received flow data in the context of intrusion detection or traffic profiling, for example

For connectionless protocols as like ICMP and UDP, a flow is considered complete once no more packets for this flow appear after configurable timeout.

NetFlow is usually enabled on a per-interface basis to limit load on the router components involved in NetFlow, or to limit the amount of NetFlow records exported.

## Configuration

In order for flow accounting information to be collected and displayed for an interface, the interface must be configured for flow accounting.

**set system flow-accounting interface <interface>**

Configure and enable collection of flow information for the interface identified by *<interface>*.

You can configure multiple interfaces which would participate in flow accounting.

---

**Bemerkung:** Will be recorded only packets/flows on **incoming** direction in configured interfaces by default.

---

By default, recorded flows will be saved internally and can be listed with the CLI command. You may disable using the local in-memory table with the command:

**set system flow-accounting disable-imt**

If you need to sample also egress traffic, you may want to configure egress flow-accounting:

**set system flow-accounting enable-egress**

Internally, in flow-accounting processes exist a buffer for data exchanging between core process and plugins (each export target is a separated plugin). If you have high traffic levels or noted some problems with missed records or stopping exporting, you may try to increase a default buffer size (10 MiB) with the next command:

**set system flow-accounting buffer-size <buffer size>**

In case, if you need to catch some logs from flow-accounting daemon, you may configure logging facility:

**set system flow-accounting syslog-facility <facility>**

TBD

## Flow Export

In addition to displaying flow accounting information locally, one can also exported them to a collection server.

### NetFlow

**set system flow-accounting netflow version <version>**

There are multiple versions available for the NetFlow data. The <version> used in the exported flow data can be configured here. The following versions are supported:

- **5** - Most common version, but restricted to IPv4 flows only
- **9** - NetFlow version 9 (default)
- **10** - IPFIX (IP Flow Information Export) as per [RFC 3917](#)

**set system flow-accounting netflow server <address>**

Configure address of NetFlow collector. NetFlow server at <address> can be both listening on an IPv4 or IPv6 address.

**set system flow-accounting netflow source-ip <address>**

IPv4 or IPv6 source address of NetFlow packets

**set system flow-accounting netflow engine-id <id>**

NetFlow engine-id which will appear in NetFlow data. The range is 0 to 255.

**set system flow-accounting netflow sampling-rate <rate>**

Use this command to configure the sampling rate for flow accounting. The system samples one in every <rate> packets, where <rate> is the value configured for the sampling-rate option. The advantage of sampling every n packets, where n > 1, allows you to decrease the amount of processing resources required for flow accounting. The disadvantage of not sampling every packet is that the statistics produced are estimates of actual data flows.

Per default every packet is sampled (that is, the sampling rate is 1).

**set system flow-accounting netflow timeout expiry-interval <interval>**

Specifies the interval at which Netflow data will be sent to a collector. As per default, Netflow data will be sent every 60 seconds.

You may also additionally configure timeouts for different types of connections.

**set system flow-accounting netflow max-flows <n>**

If you want to change the maximum number of flows, which are tracking simultaneously, you may do this with this command (default 8192).

### sFlow

**set system flow-accounting sflow server <address>**

Configure address of sFlow collector. sFlow server at <address> can be an IPv4 or IPv6 address. But you cannot export to both IPv4 and IPv6 collectors at the same time!

**set system flow-accounting sflow sampling-rate <rate>**

Enable sampling of packets, which will be transmitted to sFlow collectors.

**set system flow-accounting sflow agent-address <address>**

Configure a sFlow agent address. It can be IPv4 or IPv6 address, but you must set the same protocol, which is used for sFlow collector addresses. By default, using router-id from BGP or OSPF protocol, or the primary IP address from the first interface.

### Example:

NetFlow v5 example:

```
set system flow-accounting netflow engine-id 100
set system flow-accounting netflow version 5
set system flow-accounting netflow server 192.168.2.10 port 2055
```

### Operation

Once flow accounting is configured on an interfaces it provides the ability to display captured network traffic information for all configured interfaces.

#### show flow-accounting interface <interface>

Show flow accounting information for given <interface>.

```
vyos@vyos:~$ show flow-accounting interface eth0
```

IN_IFACE	SRC_MAC	DST_MAC	SRC_IP				DST_IP
→	SRC_PORT	DST_PORT	PROTOCOL	TOS	PACKETS	FLows	BYTES
-----	-----	-----	-----	-----	-----	-----	-----
eth0	00:53:01:a8:28:ac	ff:ff:ff:ff:ff:ff	192.0.2.2				255.255.
→255.255	5678	5678	udp	0	1	1	178
eth0	00:53:01:b2:2f:34	33:33:ff:00:00:00	fe80::253:01ff:feb2:2f34				
→ff02::1:ff00:0		0	0	ipv6-icmp	0	2	1
→144							
eth0	00:53:01:1a:b4:53	33:33:ff:00:00:00	fe80::253:01ff:fe1a:b453				
→ff02::1:ff00:0		0	0	ipv6-icmp	0	1	1
→72

### 8.11.5 FRR

VyOS uses [FRRouting](<https://frrouting.org/>) as the control plane for dynamic and static routing. The routing daemon behavior can be adjusted during runtime, but require either a restart of the routing daemon, or a reboot of the system.

#### set system frr bmp

Enable BMP (BGP Monitoring Protocol) support

#### set system frr descriptors <numer>

This allows the operator to control the number of open file descriptors each daemon is allowed to start with. If the operator plans to run bgp with several thousands of peers then this is where we would modify FRR to allow this to happen.

#### set system frr irdp

Enable ICMP Router Discovery Protocol support

#### set system frr snmp <daemon>

Enable SNMP support for an individual routing daemon.

Supported daemons:

- bgpd
- isisd
- ldpd
- ospf6d
- ospfd
- ripd
- zebra

### 8.11.6 Host Information

This section describes the system's host information and how to configure them, it covers the following topics:

- Host name
- Domain
- IP address
- Aliases

## Hostname

A hostname is the label (name) assigned to a network device (a host) on a network and is used to distinguish one device from another on specific networks or over the internet. On the other hand this will be the name which appears on the command line prompt.

**set system host-name <hostname>**

The hostname can be up to 63 characters. A hostname must start and end with a letter or digit, and have as interior characters only letters, digits, or a hyphen.

The default hostname used is *vyos*.

## Domain Name

A domain name is the label (name) assigned to a computer network and is thus unique. VyOS appends the domain name as a suffix to any unqualified name. For example, if you set the domain name *example.com*, and you would ping the unqualified name of *crux*, then VyOS qualifies the name to *crux.example.com*.

**set system domain-name <domain>**

Configure system domain name. A domain name must start and end with a letter or digit, and have as interior characters only letters, digits, or a hyphen.

## Static Hostname Mapping

How an IP address is assigned to an interface in *Ethernet*. This section shows how to statically map an IP address to a hostname for local (meaning on this VyOS instance) name resolution. This is the VyOS equivalent to */etc/hosts* file entries.

---

**Bemerkung:** Do *not* manually edit */etc/hosts*. This file will automatically be regenerated on boot based on the settings in this section, which means you'll lose all your manual edits. Instead, configure static host mappings as follows.

---

**set system static-host-mapping host-name <hostname> inet <address>**

Create a static hostname mapping which will always resolve the name *<hostname>* to IP address *<address>*.

**set system static-host-mapping host-name <hostname> alias <alias>**

Create named *<alias>* for the configured static mapping for *<hostname>*. Thus the address configured as **set system static-host-mapping host-name <hostname> inet <address>** can be reached via multiple names.

Multiple aliases can be specified per host-name.

## 8.11.7 IP

### System configuration commands

**set system ip disable-forwarding**

Use this command to disable IPv4 forwarding on all interfaces.

**set system ip disable-directed-broadcast**

Use this command to disable IPv4 directed broadcast forwarding on all interfaces.

If set, IPv4 directed broadcast forwarding will be completely disabled regardless of whether per-interface directed broadcast forwarding is enabled or not.

**set system ip arp table-size <number>**

Use this command to define the maximum number of entries to keep in the ARP cache (1024, 2048, 4096, 8192, 16384, 32768).

**set system ip multipath layer4-hashing**

Use this command to use Layer 4 information for IPv4 ECMP hashing.

## Zebra/Kernel route filtering

Zebra supports prefix-lists and Route Maps to match routes received from other FRR components. The permit/deny facilities provided by these commands can be used to filter which routes zebra will install in the kernel.

**set system ip protocol <protocol> route-map <route-map>**

Apply a route-map filter to routes for the specified protocol. The following protocols can be used: any, babel, bgp, connected, eigrp, isis, kernel, ospf, rip, static, table

---

**Bemerkung:** If you choose any as the option that will cause all protocols that are sending routes to zebra.

---

## Nexthop Tracking

Nexthop tracking resolve nexthops via the default route by default. This is enabled by default for a traditional profile of FRR which we use. It and can be disabled if you do not want to e.g. allow BGP to peer across the default route.

**set system ip nht no-resolve-via-default**

Do not allow IPv4 nexthop tracking to resolve via the default route. This parameter is configured per-VRF, so the command is also available in the VRF subnode.

## Operational commands

### show commands

See below the different parameters available for the IPv4 **show** command:

```
vyos@vyos:~$ show ip
Possible completions:
  access-list      Show all IP access-lists
  as-path-access-list
                    Show all as-path-access-lists
  bgp              Show Border Gateway Protocol (BGP) information
  community-list
                    Show IP community-lists
  extcommunity-list
                    Show extended IP community-lists
  forwarding       Show IP forwarding status
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

groups	Show IP multicast group membership
igmp	Show IGMP (Internet Group Management Protocol) information
large-community-list	Show IP large-community-lists
multicast	Show IP multicast
ospf	Show IPv4 Open Shortest Path First (OSPF) routing information
pim	Show PIM (Protocol Independent Multicast) information
ports	Show IP ports in use by various system services
prefix-list	Show all IP prefix-lists
protocol	Show IP route-maps per protocol
rip	Show Routing Information Protocol (RIP) information
route	Show IP routes

## reset commands

And the different IPv4 **reset** commands available:

```
vyos@vyos:~$ reset ip
Possible completions:
  arp          Reset Address Resolution Protocol (ARP) cache
  bgp          Clear Border Gateway Protocol (BGP) statistics or status
  igmp         IGMP clear commands
  multicast    IP multicast routing table
  route        Reset IP route
```

## 8.11.8 IPv6

### System configuration commands

#### set system ipv6 disable-forwarding

Use this command to disable IPv6 forwarding on all interfaces.

#### set system ipv6 neighbor table-size <number>

Use this command to define the maximum number of entries to keep in the Neighbor cache (1024, 2048, 4096, 8192, 16384, 32768).

#### set system ipv6 strict-dad

Use this command to disable IPv6 operation on interface when Duplicate Address Detection fails on Link-Local address.

#### set system ipv6 multipath layer4-hashing

Use this command to use Layer 4 information for ECMP hashing.

## Zebra/Kernel route filtering

Zebra supports prefix-lists and Route Maps to match routes received from other FRR components. The permit/deny facilities provided by these commands can be used to filter which routes zebra will install in the kernel.

**set system ipv6 protocol <protocol> route-map <route-map>**

Apply a route-map filter to routes for the specified protocol. The following protocols can be used: any, babel, bgp, connected, isis, kernel, ospfv3, ripng, static, table

---

**Bemerkung:** If you choose any as the option that will cause all protocols that are sending routes to zebra.

---

## Nexthop Tracking

Nexthop tracking resolve nexthops via the default route by default. This is enabled by default for a traditional profile of FRR which we use. It and can be disabled if you do not want to e.g. allow BGP to peer across the default route.

**set system ipv6 nht no-resolve-via-default**

Do not allow IPv6 nexthop tracking to resolve via the default route. This parameter is configured per-VRF, so the command is also available in the VRF subnode.

## Operational commands

### Show commands

**show ipv6 neighbors**

Use this command to show IPv6 Neighbor Discovery Protocol information.

**show ipv6 groups**

Use this command to show IPv6 multicast group membership.

**show ipv6 forwarding**

Use this command to show IPv6 forwarding status.

**show ipv6 route**

Use this command to show IPv6 routes.

Check the many parameters available for the *show ipv6 route* command:

```
vyos@vyos:~$ show ipv6 route
Possible completions:
<Enter>          Execute the current command
<X:X::X:X>       Show IPv6 routes of given address or prefix
<X:X::X:X/M>
bgp              Show IPv6 BGP routes
cache           Show kernel IPv6 route cache
connected       Show IPv6 connected routes
forward         Show kernel IPv6 route table
isis            Show IPv6 ISIS routes
kernel          Show IPv6 kernel routes
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

ospfv3	Show IPv6 OSPF6 routes
ripng	Show IPv6 RIPNG routes
static	Show IPv6 static routes
summary	Show IPv6 routes summary
table	Show IP routes in policy table
tag	Show only routes with tag
vrf	Show IPv6 routes in VRF

### show ipv6 prefix-list

Use this command to show all IPv6 prefix lists

There are different parameters for getting prefix-list information:

```
vyos@vyos:~$ show ipv6 prefix-list
Possible completions:
<Enter>      Execute the current command
<WORD>      Show specified IPv6 prefix-list
detail      Show detail of IPv6 prefix-lists
summary     Show summary of IPv6 prefix-lists
```

### show ipv6 access-list

Use this command to show all IPv6 access lists

You can also specify which IPv6 access-list should be shown:

```
vyos@vyos:~$ show ipv6 access-list
Possible completions:
<Enter>      Execute the current command
<text>      Show specified IPv6 access-list
```

### show ipv6 ospfv3

Use this command to get information about OSPFv3.

You can get more specific OSPFv3 information by using the parameters shown below:

```
vyos@vyos:~$ show ipv6 ospfv3
Possible completions:
<Enter>      Execute the current command
area        Show OSPFv3 spf-tree information
border-routers
            Show OSPFv3 border-router (ABR and ASBR) information
database    Show OSPFv3 Link state database information
interface    Show OSPFv3 interface information
linkstate    Show OSPFv3 linkstate routing information
neighbor     Show OSPFv3 neighbor information
redistribute Show OSPFv3 redistribute External information
route        Show OSPFv3 routing table information
```

### show ipv6 ripng

Use this command to get information about the RIPNG protocol

### show ipv6 ripng status

Use this command to show the status of the RIPNG protocol

## Reset commands

**reset bgp ipv6 <address>**

Use this command to clear Border Gateway Protocol statistics or status.

**reset ipv6 neighbors <address | interface>**

Use this command to reset IPv6 Neighbor Discovery Protocol cache for an address or interface.

**reset ipv6 route cache**

Use this command to flush the kernel IPv6 route cache. An address can be added to flush it only for that route.

### 8.11.9 System Display (LCD)

The system LCD LCD (Liquid-crystal display) option is for users running VyOS on hardware that features an LCD display. This is typically a small display built in an 19 inch rack-mountable appliance. Those displays are used to show runtime data.

To configure your LCD display you must first identify the used hardware, and connectivity of the display to your system. This can be any serial port (*ttySxx*) or serial via USB or even old parallel port interfaces.

## Configuration

**set system lcd device <device>**

This is the name of the physical interface used to connect to your LCD display. Tab completion is supported and it will list you all available serial interface.

For serial via USB port information please refer to: [USB](#).

**set system lcd model <model>**

This is the LCD model used in your system.

At the time of this writing the following displays are supported:

- Crystalfontz CFA-533
- Crystalfontz CFA-631
- Crystalfontz CFA-633
- Crystalfontz CFA-635

---

**Bemerkung:** We can't support all displays from the beginning. If your display type is missing, please create a feature request via [Phabricator](#).

---

### 8.11.10 Login/User Management

The default VyOS user account (*vyos*), as well as newly created user accounts, have all capabilities to configure the system. All accounts have sudo capabilities and therefore can operate as root on the system.

Both local administered and remote administered RADIUS (Remote Authentication Dial-In User Service) accounts are supported.

#### Local

**set system login user <name> full-name „<string>“**

Create new system user with username <name> and real-name specified by <string>.

**set system login user <name> authentication plaintext-password <password>**

Specify the plaintext password user by user <name> on this system. The plaintext password will be automatically transferred into a secure hashed password and not saved anywhere in plaintext.

**set system login user <name> authentication encrypted-password <password>**

Setup encrypted password for given username. This is useful for transferring a hashed password from system to system.

**set system login user <name> disable**

Disable (lock) account. User will not be able to log in.

#### Key Based Authentication

It is highly recommended to use SSH key authentication. By default there is only one user (*vyos*), and you can assign any number of keys to that user. You can generate a ssh key with the `ssh-keygen` command on your local machine, which will (by default) save it as `~/.ssh/id_rsa.pub`.

Every SSH key comes in three parts:

```
ssh-rsa AAAAB3NzaC1yc2EAAAABAA...VBD5lKwEWB username@host.example.com
```

Only the type (`ssh-rsa`) and the key (`AAAAB3N...`) are used. Note that the key will usually be several hundred characters long, and you will need to copy and paste it. Some terminal emulators may accidentally split this over several lines. Be attentive when you paste it that it only pastes as a single line. The third part is simply an identifier, and is for your own reference.

**Siehe auch:**

SSH *Operation*

**set system login user <username> authentication public-keys <identifier> key <key>**

Assign the SSH public key portion <key> identified by per-key <identifier> to the local user <username>.

**set system login user <username> authentication public-keys <identifier> type <type>**

Every SSH public key portion referenced by <identifier> requires the configuration of the <type> of public-key used. This type can be any of:

- `ecdsa-sha2-nistp256`
- `ecdsa-sha2-nistp384`
- `ecdsa-sha2-nistp521`
- `ssh-dss`

- ssh-ed25519
- ssh-rsa

---

**Bemerkung:** You can assign multiple keys to the same user by using a unique identifier per SSH key.

---

**set system login user <username> authentication public-keys <identifier> options <options>**

Set the options for this public key. See the ssh authorized\_keys man page for details of what you can specify here. To place a " character in the options field, use &quot;, for example `from=&quot;10.0.0.0/24&quot;` to restrict where the user may connect from when using this key.

### MFA/2FA authentication using OTP (one time passwords)

It is possible to enhance authentication security by using the 2FA (Two-factor authentication)/MFA (Multi-factor authentication) feature together with OTP (One-Time-Pad) on VyOS. 2FA/MFA is configured independently per each user. If an OTP key is configured for a user, 2FA/MFA is automatically enabled for that particular user. If a user does not have an OTP key configured, there is no 2FA/MFA check for that user.

**set system login user <username> authentication otp key <key>**

Enable OTP 2FA for user *username* with default settings, using the BASE32 encoded 2FA/MFA key specified by *<key>*.

### Optional/default settings

**set system login user <username> authentication otp rate-limit <limit>** default: 3

Limit logins to *<limit>* per every *rate-time* seconds. Rate limit must be between 1 and 10 attempts.

**set system login user <username> authentication otp rate-time <seconds>** default: 30

Limit logins to *rate-limit* attempts per every *<seconds>*. Rate time must be between 15 and 600 seconds.

**set system login user <username> authentication otp window-size <size>** default: 3

Set window of concurrently valid codes.

By default, a new token is generated every 30 seconds by the mobile application. In order to compensate for possible time-skew between the client and the server, an extra token before and after the current time is allowed. This allows for a time skew of up to 30 seconds between authentication server and client.

For example, if problems with poor time synchronization are experienced, the window can be increased from its default size of 3 permitted codes (one previous code, the current code, the next code) to 17 permitted codes (the 8 previous codes, the current code, and the 8 next codes). This will permit for a time skew of up to 4 minutes between client and server.

The window size must be between 1 and 21.

## OTP-key generation

The following command can be used to generate the OTP key as well as the CLI commands to configure them:

```
generate system login username <username> otp-key hotp-time rate-limit <1-10> rate-time  
<15-600> window-size <1-21>
```

An example of key generation:

```
vyos@vyos:~$ generate system login username otptester otp-key hotp-time rate-limit 2  
↪rate-time 20 window-size 5  
# You can share it with the user, he just needs to scan the QR in his OTP app  
# username:  otptester  
# OTP KEY:   J5A64ERPMGJOZXY6FMHHLKXXKANNI6TCY  
# OTP URL:   otpauth://totp/otptester@vyos?secret=J5A64ERPMGJOZXY6FMHHLKXXKANNI6TCY&  
↪digits=6&period=30
```

# To add this OTP key to configuration, run the following commands:

```
set system login user otptester authentication otp key 'J5A64ERPMGJOZXY6FMHHLKXXKANNI6TCY'  
set system login user otptester authentication otp rate-limit '2'  
set system login user otptester authentication otp rate-time '20'  
set system login user otptester authentication otp window-size '5'
```

## Display OTP key for user

To display the configured OTP user key, use the command:

```
sh system login authentication user <username> otp <full|key-b32|qrcode|uri>
```

An example:

```
vyos@vyos:~$ sh system login authentication user otptester otp full
# You can share it with the user, he just needs to scan the QR in his OTP app
# username: otptester
# OTP KEY: J5A64ERPMGJOZXY6FMHHLKXXKANNI6TCY
# OTP URL: otpauth://totp/otptester@vyos?secret=J5A64ERPMGJOZXY6FMHHLKXXKANNI6TCY&
↳ digits=6&period=30
```

# To add this OTP key to configuration, run the following commands:

```
set system login user otptester authentication otp key 'J5A64ERPMGJOZXY6FMHHLKXXKANNI6TCY'
set system login user otptester authentication otp rate-limit '2'
set system login user otptester authentication otp rate-time '20'
set system login user otptester authentication otp window-size '5'
```

## RADIUS

In large deployments it is not reasonable to configure each user individually on every system. VyOS supports using RADIUS servers as backend for user authentication.

### Configuration

**set system login radius server <address> key <secret>**

Specify the IP <address> of the RADIUS server user with the pre-shared-secret given in <secret>.

Multiple servers can be specified.

**set system login radius server <address> port <port>**

Configure the discrete port under which the RADIUS server can be reached.

This defaults to 1812.

**set system login radius server <address> disable**

Temporary disable this RADIUS server. It won't be queried.

**set system login radius server <address> timeout <timeout>**

Setup the <timeout> in seconds when querying the RADIUS server.

**set system login radius source-address <address>**

RADIUS servers could be hardened by only allowing certain IP addresses to connect. As of this the source address of each RADIUS query can be configured.

If unset, incoming connections to the RADIUS server will use the nearest interface address pointing towards the server - making it error prone on e.g. OSPF networks when a link fails and a backup route is taken.

**set system login radius vrf <name>**

Source all connections to the RADIUS servers from given VRF <name>.

### Configuration Example

```
set system login radius server 192.168.0.2 key 'test-vyos'
set system login radius server 192.168.0.2 port '1812'
set system login radius server 192.168.0.2 timeout '5'
set system login radius source-address '192.168.0.1'
```

If there is no communication between VyOS and RADIUS server users can authenticate from local user accounts. During authentication from the local accounts users can observe some timeouts. Timeout in seconds depends on the configured timeout option.

---

**Hinweis:** If you want to have admin users to authenticate via RADIUS it is essential to sent the Cisco-AV-Pair shell:priv-lvl=15 attribute. Without the attribute you will only get regular, non privileged, system users.

---

## TACACS+

In addition to RADIUS, TACACS (Terminal Access Controller Access Control System) can also be found in large deployments.

TACACS is defined in [RFC 8907](#).

### Configuration

**set system login tacacs server <address> key <secret>**

Specify the IP <address> of the TACACS server user with the pre-shared-secret given in <secret>.

Multiple servers can be specified.

**set system login tacacs server <address> port <port>**

Configure the discrete port under which the TACACS server can be reached.

This defaults to 49.

**set system login tacacs server <address> disable**

Temporary disable this TACACS server. It won't be queried.

**set system login tacacs server <address> timeout <timeout>**

Setup the <timeout> in seconds when querying the TACACS server.

**set system login tacacs source-address <address>**

TACACS servers could be hardened by only allowing certain IP addresses to connect. As of this the source address of each TACACS query can be configured.

If unset, incoming connections to the TACACS server will use the nearest interface address pointing towards the server - making it error prone on e.g. OSPF networks when a link fails and a backup route is taken.

**set system login tacacs vrf <name>**

Source all connections to the TACACS servers from given VRF <name>.

### Configuration Example

```
set system login tacacs server 192.168.0.2 key 'test-vyos'
set system login tacacs server 192.168.0.2 port '49'
set system login tacacs source-address '192.168.0.1'
```

If there is no communication between VyOS and TACACS server users can authenticate from local user accounts.

## Login Banner

You are able to set post-login or pre-login banner messages to display certain information for this system.

**set system login banner pre-login <message>**

Configure <message> which is shown during SSH connect and before a user is logged in.

**set system login banner post-login <message>**

Configure <message> which is shown after user has logged in to the system.

---

**Bemerkung:** To create a new line in your login message you need to escape the new line character by using `\\n`.

---

## Limits

Login limits

**set system login max-login-session <number>**

Set a limit on the maximum number of concurrent logged-in users on the system.

This option must be used with `timeout` option.

**set system login timeout <timeout>**

Configure session timeout after which the user will be logged out.

## Example

In the following example, both *User1* and *User2* will be able to SSH into VyOS as user `vyos` using their very own keys. *User1* is restricted to only be able to connect from a single IP address. In addition if password base login is wanted for the `vyos` user a 2FA/MFA keycode is required in addition to the password.

```
set system login user vyos authentication public-keys 'User1' key "AAAAB3Nz...KwEW"
set system login user vyos authentication public-keys 'User1' type ssh-rsa
set system login user vyos authentication public-keys 'User1' options "from=&quot;192.
↪168.0.100&quot;"

set system login user vyos authentication public-keys 'User2' key "AAAAQ39x...fbV3"
set system login user vyos authentication public-keys 'User2' type ssh-rsa

set system login user vyos authentication otp key OHZ30J7U2N25BK4G7SOFFJTZDTCFUUE2
set system login user vyos authentication plaintext-password vyos
```

## TACACS Example

We use a container providing the TACACS server in this example.

Load the container image in op-mode.

```
add container image lfkeitel/tacacs_plus:latest

set container network tac-test prefix '100.64.0.0/24'

set container name tacacs1 image 'lfkeitel/tacacs_plus:latest'
set container name tacacs1 network tac-test address '100.64.0.11'

set container name tacacs2 image 'lfkeitel/tacacs_plus:latest'
set container name tacacs2 network tac-test address '100.64.0.12'

set system login tacacs server 100.64.0.11 key 'tac_plus_key'
set system login tacacs server 100.64.0.12 key 'tac_plus_key'

commit
```

You can now SSH into your system using admin/admin as a default user supplied from the lfkeitel/tacacs\_plus:latest container.

### 8.11.11 System DNS

**Warnung:** If you are configuring a VRF for management purposes, there is currently no way to force system DNS traffic via a specific VRF.

This section describes configuring DNS on the system, namely:

- DNS name servers
- Domain search order

#### DNS name servers

**set system name-server <address>**

Use this command to specify a DNS server for the system to be used for DNS lookups. More than one DNS server can be added, configuring one at a time. Both IPv4 and IPv6 addresses are supported.

## Example

In this example, some *OpenNIC* servers are used, two IPv4 addresses and two IPv6 addresses:

```
set system name-server 176.9.37.132
set system name-server 195.10.195.195
set system name-server 2a01:4f8:161:3441::1
set system name-server 2a00:f826:8:2::195
```

## Domain search order

In order for the system to use and complete unqualified host names, a list can be defined which will be used for domain searches.

**set system domain-search <domain>**

Use this command to define domains, one at a time, so that the system uses them to complete unqualified host names. Maximum: 6 entries.

**Bemerkung:** Domain names can include letters, numbers, hyphens and periods with a maximum length of 253 characters.

## Example

The system is configured to attempt domain completion in the following order: vyos.io (first), vyos.net (second) and vyos.network (last):

```
set system domain-search vyos.io
set system domain-search vyos.net
set system domain-search vyos.network
```

## 8.11.12 Option

This chapter describe the possibilities of advanced system behavior.

### General

**set system option ctrl-alt-delete <ignore | reboot | poweroff>**

Action which will be run once the ctrl-alt-del keystroke is received.

**set system option reboot-on-panic**

Automatically reboot system on kernel panic after 60 seconds.

**set system option startup-beep**

Play an audible beep to the system speaker when system is ready.

**set system option root-partition-auto-resize**

Enables the root partition auto-extension and resizes to the maximum available space on system boot.

## Kernel

### **set system option kernel disable-mitigations**

Disable all optional CPU mitigations. This improves system performance, but it may also expose users to several CPU vulnerabilities.

This will add the following option to the Kernel commandline:

- mitigations=off

---

**Bemerkung:** Setting will only become active with the next reboot!

---

### **set system option kernel disable-power-saving**

Disable CPU power saving mechanisms also known as C states.

This will add the following two options to the Kernel commandline:

- intel\_idle.max\_cstate=0 Disable intel\_idle and fall back on acpi\_idle
- processor.max\_cstate=1 Limit processor to maximum C-state 1

---

**Bemerkung:** Setting will only become active with the next reboot!

---

## HTTP client

### **set system option http-client source-address <address>**

Several commands utilize cURL to initiate transfers. Configure the local source IPv4/IPv6 address used for all cURL operations.

### **set system option http-client source-interface <interface>**

Several commands utilize curl to initiate transfers. Configure the local source interface used for all CURL operations.

---

**Bemerkung:** *source-address* and *source-interface* can not be used at the same time.

---

## SSH client

### **set system option ssh-client source-address <address>**

Use the specified address on the local machine as the source address of the connection. Only useful on systems with more than one address.

### **set system option ssh-client source-interface <interface>**

Use the address of the specified interface on the local machine as the source address of the connection.

## Keyboard Layout

When starting a VyOS live system (the installation CD) the configured keyboard layout defaults to US. As this might not suite everyone's use case you can adjust the used keyboard layout on the system console.

```
set system option keyboard-layout <us | fr | de | fi | no | dk>
```

Change system keyboard layout to given language.

Defaults to us.

---

**Bemerkung:** Changing the keymap only has an effect on the system console, using SSH or Serial remote access to the device is not affected as the keyboard layout here corresponds to your access system.

---

## Performance

As more and more routers run on Hypervisors, expecially with a NOS (Network Operating System) as VyOS, it makes fewer and fewer sense to use static resource bindings like `smp-affinity` as present in VyOS 1.2 and earlier to pin certain interrupt handlers to specific CPUs.

We now utilize *tuned* for dynamic resource balancing based on profiles.

**Siehe auch:**

<https://access.redhat.com/sites/default/files/attachments/201501-perf-brief-low-latency-tuning-rhel7-v2.1.pdf>

```
set system option performance < throughput | latency >
```

Configure one of the predefined system performance profiles.

- **throughput:** A server profile focused on improving network throughput. This profile favors performance over power savings by setting `intel_pstate` and `max_perf_pct=100` and increasing kernel network buffer sizes.

It enables transparent huge pages, and uses `cpupower` to set the performance `cpufreq` governor. It also sets `kernel.sched_min_granularity_ns` to 10 us, `kernel.sched_wakeup_granularity_ns` to 15 uss, and `vm.dirty_ratio` to 40%.

- **latency:** A server profile focused on lowering network latency. This profile favors performance over power savings by setting `intel_pstate` and `min_perf_pct=100`.

It disables transparent huge pages, and automatic NUMA balancing. It also uses `cpupower` to set the performance `cpufreq` governor, and requests a `cpu_dma_latency` value of 1. It also sets `busy_read` and `busy_poll` times to 50 us, and `tcp_fastopen` to 3.

### 8.11.13 System Proxy

Some IT environments require the use of a proxy to connect to the Internet. Without this configuration VyOS updates could not be installed directly by using the `add system image` command (*Update VyOS*).

```
set system proxy url <url>
```

Set proxy for all connections initiated by VyOS, including HTTP, HTTPS, and FTP (anonymous ftp).

```
set system proxy port <port>
```

Configure proxy port if it does not listen to the default port 80.

```
set system proxy username <username>
```

Some proxys require/support the „basic“ HTTP authentication scheme as per [RFC 7617](#), thus a username can be configured.

**set system proxy password <password>**

Some proxys require/support the „basic“ HTTP authentication scheme as per [RFC 7617](#), thus a password can be configured.

### 8.11.14 sFlow

VyOS supports sFlow accounting for both IPv4 and IPv6 traffic. The system acts as a flow exporter, and you are free to use it with any compatible collector.

sFlow is a technology that enables monitoring of network traffic by sending sampled packets to a collector device.

The sFlow accounting based on hsfowd <https://sflow.net/>

#### Configuration

**set system sflow agent-address <address>**

Configure sFlow agent IPv4 or IPv6 address

**set system sflow agent-interface <interface>**

Configure agent IP address associated with this interface.

**set system sflow drop-monitor-limit <limit>**

Dropped packets reported on DROPMON Netlink channel by Linux kernel are exported via the standard sFlow v5 extension for reporting dropped packets

**set system sflow interface <interface>**

Configure and enable collection of flow information for the interface identified by <interface>.

You can configure multiple interfaces which would participate in sflow accounting.

**set system sflow polling <sec>**

Configure schedule counter-polling in seconds (default: 30)

**set system sflow sampling-rate <rate>**

Use this command to configure the sampling rate for sFlow accounting (default: 1000)

**set system sflow server <address> port <port>**

Configure address of sFlow collector. sFlow server at <address> can be both listening on an IPv4 or IPv6 address.

#### Example

```
set system sflow agent-address '192.0.2.14'
set system sflow agent-interface 'eth0'
set system sflow drop-monitor-limit '50'
set system sflow interface 'eth0'
set system sflow interface 'eth1'
set system sflow polling '30'
set system sflow sampling-rate '1000'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set system sflow server 192.0.2.1 port '6343'
set system sflow server 203.0.113.23 port '6343'
```

### 8.11.15 Syslog

Per default VyOSs has minimal syslog logging enabled which is stored and rotated locally. Errors will be always logged to a local file, which includes *local7* error messages, emergency messages will be sent to the console, too.

To configure syslog, you need to switch into configuration mode.

#### Logging

Syslog supports logging to multiple targets, those targets could be a plain file on your VyOS installation itself, a serial console or a remote syslog server which is reached via IP (Internet Protocol) UDP/TCP.

#### Console

```
set system syslog console facility <keyword> level <keyword>
```

Log syslog messages to `/dev/console`, for an explanation on *Facilities* keywords and *Severity Level* keywords see tables below.

#### Custom File

```
set system syslog file <filename> facility <keyword> level <keyword>
```

Log syslog messages to file specified via `<filename>`, for an explanation on *Facilities* keywords and *Severity Level* keywords see tables below.

```
set system syslog file <filename> archive size <size>
```

Syslog will write `<size>` kilobytes into the file specified by `<filename>`. After this limit has been reached, the custom file is „rotated“ by logrotate and a new custom file is created.

```
set system syslog file <filename> archive file <number>
```

Syslog uses logrotate to rotate logfiles after a number of gives bytes. We keep as many as `<number>` rotated file before they are deleted on the system.

#### Remote Host

Logging to a remote host leaves the local logging configuration intact, it can be configured in parallel to a custom file or console logging. You can log to multiple hosts at the same time, using either TCP or UDP. The default is sending the messages via port 514/UDP.

```
set system syslog host <address> facility <keyword> level <keyword>
```

Log syslog messages to remote host specified by `<address>`. The address can be specified by either FQDN or IP address. For an explanation on *Facilities* keywords and *Severity Level* keywords see tables below.

```
set system syslog host <address> facility <keyword> protocol <udp|tcp>
```

Configure protocol used for communication to remote syslog host. This can be either UDP or TCP.

```
set system syslog vrf <name>
```

Specify name of the VRF instance.

## Local User Account

```
set system syslog user <username> facility <keyword> level <keyword>
```

If logging to a local user account is configured, all defined log messages are display on the console if the local user is logged in, if the user is not logged in, no messages are being displayed. For an explanation on [Facilities](#) keywords and [Severity Level](#) keywords see tables below.

## Facilities

List of facilities used by syslog. Most facilities names are self explanatory. Facilities local0 - local7 common usage is f.e. as network logs facilities for nodes and network equipment. Generally it depends on the situation how to classify logs and put them to facilities. See facilities more as a tool rather than a directive to follow.

Facilities can be adjusted to meet the needs of the user:

Facility Code	Keyword	Description
	all	All facilities
0	kern	Kernel messages
1	user	User-level messages
2	mail	Mail system
3	daemon	System daemons
4	auth	Security/authentication messages
5	syslog	Messages generated internally by syslogd
6	lpr	Line printer subsystem
7	news	Network news subsystem
8	uucp	UUCP subsystem
9	cron	Clock daemon
10	security	Security/authentication messages
11	ftp	FTP daemon
12	ntp	NTP subsystem
13	logaudit	Log audit
14	logalert	Log alert
15	clock	clock daemon (note 2)
16	local0	local use 0 (local0)
17	local1	local use 1 (local1)
18	local2	local use 2 (local2)
19	local3	local use 3 (local3)
20	local4	local use 4 (local4)
21	local5	local use 5 (local5)
22	local6	use 6 (local6)
23	local7	local use 7 (local7)

## Severity Level

Value	Severity	Key-word	Description
0	Emergency	all emerg	Log everything System is unusable - a panic condition
1	Alert	alert	Action must be taken immediately - A condition that should be corrected immediately, such as a corrupted system database.
2	Critical	crit	Critical conditions - e.g. hard drive errors.
3	Error	err	Error conditions
4	Warning	warning	Warning conditions
5	Notice	notice	Normal but significant conditions - conditions that are not error conditions, but that may require special handling.
6	Informational	info	Informational messages
7	Debug	debug	Debug-level messages - Messages that contain information normally of use only when debugging a program.

## Display Logs

**show log [all | authorization | cluster | conntrack-sync | ...]**

Display log files of given category on the console. Use tab completion to get a list of available categories. Those categories could be: all, authorization, cluster, conntrack-sync, dhcp, directory, dns, file, firewall, https, image lldp, nat, openvpn, snmp, tail, vpn, vrrp

If no option is specified, this defaults to *all*.

**show log image <name> [all | authorization | directory | file <file name> | tail <lines>]**

Log messages from a specified image can be displayed on the console. Details of allowed parameters:

all	Display contents of all master log files of the specified image
authorization	Display all authorization attempts of the specified image
directory	Display list of all user-defined log files of the specified image
file <file name>	Display contents of a specified user-defined log file of the specified image
tail	Display last lines of the system log of the specified image
<lines>	Number of lines to be displayed, default 10

When no options/parameters are used, the contents of the main syslog file are displayed.

---

**Hinweis:** Use `show log | strip-private` if you want to hide private data when sharing your logs.

---

## Delete Logs

### **delete log file <text>**

Deletes the specified user-defined file <text> in the /var/log/user directory

Note that deleting the log file does not stop the system from logging events. If you use this command while the system is logging events, old log events will be deleted, but events after the delete operation will be recorded in the new file. To delete the file altogether, first delete logging to the file using system syslog *Custom File* command, and then delete the file.

## 8.11.16 Sysctl

This chapter describes how to configure kernel parameters at runtime.

sysctl is used to modify kernel parameters at runtime. The parameters available are those listed under /proc/sys/.

### **set system sysctl parameter <parameter> value <value>**

## 8.11.17 Task Scheduler

The task scheduler allows you to execute tasks on a given schedule. It makes use of UNIX *cron*.

---

**Bemerkung:** All scripts executed this way are executed as root user - this may be dangerous. Together with *Command Scripting* this can be used for automating (re-)configuration.

---

### **set system task-scheduler task <task> interval <interval>**

Specify the time interval when <task> should be executed. The interval is specified as number with one of the following suffixes:

- none - Execution interval in minutes
- m - Execution interval in minutes
- h - Execution interval in hours
- d - Execution interval in days

---

**Bemerkung:** If suffix is omitted, minutes are implied.

---

### **set system task-scheduler task <task> crontab-spec <spec>**

Set execution time in common *cron* time format. A cron <spec> of 30 \*/6 \* \* \* would execute the <task> at minute 30 past every 6th hour.

### **set system task-scheduler task <task> executable path <path>**

Specify absolute <path> to script which will be run when <task> is executed.

### **set system task-scheduler task <task> executable arguments <args>**

Arguments which will be passed to the executable.

### 8.11.18 Time Zone

Time Zone setting is very important as e.g all your logfile entries will be based on the configured zone. Without proper time zone configuration it will be very difficult to compare logfiles from different systems.

**set system time-zone <timezone>**

Specify the systems <timezone> as the Region/Location that best defines your location. For example, specifying US/Pacific sets the time zone to US Pacific time.

Command completion can be used to list available time zones. The adjustment for daylight time will take place automatically based on the time of year.

### 8.11.19 Updates

VyOS supports online checking for updates

#### Configuration

**set system update-check auto-check**

Configure auto-checking for new images

**set system update-check url <url>**

Configure a URL that contains information about images.

#### Example

```
set system update-check auto-check
set system update-check url 'https://raw.githubusercontent.com/vyos/vyos-rolling-nightly-
↳ builds/main/version.json'
```

Check:

```
vyos@r4:~$ show system updates
Current version: 1.5-rolling-202312220023

Update available: 1.5-rolling-202312250024
Update URL: https://github.com/vyos/vyos-rolling-nightly-builds/releases/download/1.5-
↳ rolling-202312250024/1.5-rolling-202312250024-amd64.iso
vyos@r4:~$

vyos@r4:~$ add system image latest
```

## 8.11.20 Default Gateway/Route

In the past (VyOS 1.1) used a gateway-address configured under the system tree (`set system gateway-address <address>`), this is no longer supported and existing configurations are migrated to the new CLI command.

### Configuration

**set protocols static route 0.0.0.0/0 next-hop <address>**

Specify static route into the routing table sending all non local traffic to the nexthop address *<address>*.

**delete protocols static route 0.0.0.0/0**

Delete default route from the system.

### Operation

**show ip route 0.0.0.0**

Show routing table entry for the default route.

```
vyos@vyos:~$ show ip route 0.0.0.0
Routing entry for 0.0.0.0/0
  Known via "static", distance 10, metric 0, best
  Last update 09:46:30 ago
  * 172.18.201.254, via eth0.201
```

**Siehe auch:**

Configuration of *Static*

## 8.12 Traffic Policy

### 8.12.1 QoS

The generic name of Quality of Service or Traffic Control involves things like shaping traffic, scheduling or dropping packets, which are the kind of things you may want to play with when you have, for instance, a bandwidth bottleneck in a link and you want to somehow prioritize some type of traffic over another.

`tc` is a powerful tool for Traffic Control found at the Linux kernel. However, its configuration is often considered a cumbersome task. Fortunately, VyOS eases the job through its CLI, while using `tc` as backend.

### How to make it work

In order to have VyOS Traffic Control working you need to follow 2 steps:

1. **Create a traffic policy.**
2. **Apply the traffic policy to an interface ingress or egress.**

But before learning to configure your policy, we will warn you about the different units you can use and also show you what *classes* are and how they work, as some policies may require you to configure them.

## Units

When configuring your traffic policy, you will have to set data rate values, watch out the units you are managing, it is easy to get confused with the different prefixes and suffixes you can use. VyOS will always show you the different units you can use.

## Prefixes

They can be **decimal** prefixes.

```
kbit (10^3)    kilobit per second
mbit (10^6)    megabit per second
gbit (10^9)    gigabit per second
tbit (10^12)   terabit per second

kbits (8*10^3) kilobyte per second
mbits (8*10^6) megabyte per second
gbits (8*10^9) gigabyte per second
tbits (8*10^12) terabyte per second
```

Or **binary** prefixes.

```
kibit (2^10 = 1024) kibibit per second
mibit (2^20 = 1024^2) mebibit per second
gibit (2^30 = 1024^3) gibibit per second
tbit (2^40 = 1024^4) tebibit per second

kibps (1024*8)      kibibyte (KiB) per second
mibps (1024^2*8)    mebibyte (MiB) per second
gibps (1024^3*8)    gibibyte (GiB) per second
tibps (1024^4*8)    tebibyte (TiB) per second
```

## Suffixes

A *bit* is written as **bit**,

```
kbit (kilobits per second)
mbit (megabits per second)
gbit (gigabits per second)
tbit (terabits per second)
```

while a *byte* is written as a single **b**.

```
kbps (kilobytes per second)
mbps (megabytes per second)
gbps (gigabytes per second)
```

## Classes

In the *Creating a traffic policy* section you will see that some of the policies use *classes*. Those policies let you distribute traffic into different classes according to different parameters you can choose. So, a class is just a specific type of traffic you select.

The ultimate goal of classifying traffic is to give each class a different treatment.

## Matching traffic

In order to define which traffic goes into which class, you define filters (that is, the matching criteria). Packets go through these matching rules (as in the rules of a firewall) and, if a packet matches the filter, it is assigned to that class.

In VyOS, a class is identified by a number you can choose when configuring it.

---

**Bemerkung:** The meaning of the Class ID is not the same for every type of policy. Normally policies just need a meaningless number to identify a class (Class ID), but that does not apply to every policy. The number of a class in a Priority Queue it does not only identify it, it also defines its priority.

---

```
set qos policy <policy> <policy-name> class <class-ID> match <class-matching-rule-name>
```

In the command above, we set the type of policy we are going to work with and the name we choose for it; a class (so that we can differentiate some traffic) and an identifiable number for that class; then we configure a matching rule (or filter) and a name for it.

A class can have multiple match filters:

```
set qos policy shaper MY-SHAPER class 30 match HTTP
set qos policy shaper MY-SHAPER class 30 match HTTPs
```

A match filter can contain multiple criteria and will match traffic if all those criteria are true.

For example:

```
set qos policy shaper MY-SHAPER class 30 match HTTP ip protocol tcp
set qos policy shaper MY-SHAPER class 30 match HTTP ip source port 80
```

This will match TCP traffic with source port 80.

There are many parameters you will be able to use in order to match the traffic you want for a class:

- **Ethernet (protocol, destination address or source address)**
- **Interface name**
- **IPv4 (DSCP value, maximum packet length, protocol, source address, destination address, source port, destination port or TCP flags)**
- **IPv6 (DSCP value, maximum payload length, protocol, source address, destination address, source port, destination port or TCP flags)**
- **Firewall mark**
- **VLAN ID**

When configuring your filter, you can use the Tab key to see the many different parameters you can configure.

```
vyos@vyos# set qos policy shaper MY-SHAPER class 30 match MY-FIRST-FILTER
```

Possible completions:

description	Description
> ether	Ethernet header match
interface	Interface to use
> ip	Match IP protocol header
> ipv6	Match IPV6 protocol header
mark	Match on mark applied by firewall
vif	Virtual Local Area Network (VLAN) ID for this match

As shown in the example above, one of the possibilities to match packets is based on marks done by the firewall, [that can give you a great deal of flexibility](#).

You can also write a description for a filter:

```
set qos policy shaper MY-SHAPER class 30 match MY-FIRST-FILTER description "My filter_
↪description"
```

---

**Bemerkung:** An IPv4 TCP filter will only match packets with an IPv4 header length of 20 bytes (which is the majority of IPv4 packets anyway).

---

---

**Bemerkung:** IPv6 TCP filters will only match IPv6 packets with no header extension, see [https://en.wikipedia.org/wiki/IPv6\\_packet#Extension\\_headers](https://en.wikipedia.org/wiki/IPv6_packet#Extension_headers)

---

## Default

Often you will also have to configure your *default* traffic in the same way you do with a class. *Default* can be considered a class as it behaves like that. It contains any traffic that did not match any of the defined classes, so it is like an open class, a class without matching filters.

## Class treatment

Once a class has a filter configured, you will also have to define what you want to do with the traffic of that class, what specific Traffic-Control treatment you want to give it. You will have different possibilities depending on the Traffic Policy you are configuring.

```
vyos@vyos# set qos policy shaper MY-SHAPER class 30
```

Possible completions:

bandwidth	Available bandwidth for this policy (default: auto)
burst	Burst size for this class (default: 15k)
ceiling	Bandwidth limit for this class
codel-quantum	Deficit in the fair queuing algorithm (default 1514)
description	Description
flows	Number of flows into which the incoming packets are classified(default_
↪1024)	
interval	Interval used to measure the delay (default 100)
+> match	Class matching rule name

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

priority	Priority for rule evaluation
queue-limit	Maximum queue size
queue-type	Queue type for default traffic (default: fq-codel)
set-dscp	Change the Differentiated Services (DiffServ) field in the IP header
target	Acceptable minimum standing/persistent queue delay (default: 5)

For instance, with `set qos policy shaper MY-SHAPER class 30 set-dscp EF` you would be modifying the DSCP field value of packets in that class to Expedite Forwarding.

DSCP values as per [RFC 2474](#) and [RFC 4595](#):

Binary value	Configured value	Drop rate	Description
101110	46	.	Expedited forwarding (EF)
000000	0	.	Best effort traffic, default
001010	10	Low	Assured Forwarding(AF) 11
001100	12	Medium	Assured Forwarding(AF) 12
001110	14	High	Assured Forwarding(AF) 13
010010	18	Low	Assured Forwarding(AF) 21
010100	20	Medium	Assured Forwarding(AF) 22
010110	22	High	Assured Forwarding(AF) 23
011010	26	Low	Assured Forwarding(AF) 31
011100	28	Medium	Assured Forwarding(AF) 32
011110	30	High	Assured Forwarding(AF) 33
100010	34	Low	Assured Forwarding(AF) 41
100100	36	Medium	Assured Forwarding(AF) 42
100110	38	High	Assured Forwarding(AF) 43

## Embedding one policy into another one

Often we need to embed one policy into another one. It is possible to do so on classful policies, by attaching a new policy into a class. For instance, you might want to apply different policies to the different classes of a Round-Robin policy you have configured.

A common example is the case of some policies which, in order to be effective, they need to be applied to an interface that is directly connected where the bottleneck is. If your router is not directly connected to the bottleneck, but some hop before it, you can emulate the bottleneck by embedding your non-shaping policy into a classful shaping one so that it takes effect.

You can configure a policy into a class through the `queue-type` setting.

```
set qos policy shaper FQ-SHAPER bandwidth 4gbit
set qos policy shaper FQ-SHAPER default bandwidth 100%
set qos policy shaper FQ-SHAPER default queue-type fq-codel
```

As shown in the last command of the example above, the *queue-type* setting allows these combinations. You will be able to use it in many policies.

---

**Bemerkung:** Some policies already include other embedded policies inside. That is the case of *Shaper*: each of its classes use fair-queue unless you change it.

---

## Creating a traffic policy

VyOS lets you control traffic in many different ways, here we will cover every possibility. You can configure as many policies as you want, but you will only be able to apply one policy per interface and direction (inbound or outbound).

Some policies can be combined, you will be able to *embed* a different policy that will be applied to a class of the main policy.

---

**Hinweis:** If you are looking for a policy for your outbound traffic but you don't know which one you need and you don't want to go through every possible policy shown here, **our bet is that highly likely you are looking for a *Shaper* policy and you want to *set its queues* as FQ-CoDel.**

---

## Drop Tail

**Queueing discipline:** PFIFO (Packet First In First Out).

**Applies to:** Outbound traffic.

This the simplest queue possible you can apply to your traffic. Traffic must go through a finite queue before it is actually sent. You must define how many packets that queue can contain.

When a packet is to be sent, it will have to go through that queue, so the packet will be placed at the tail of it. When the packet completely goes through it, it will be dequeued emptying its place in the queue and being eventually handed to the NIC to be actually sent out.

Despite the Drop-Tail policy does not slow down packets, if many packets are to be sent, they could get dropped when trying to get enqueued at the tail. This can happen if the queue has still not been able to release enough packets from its head.

This is the policy that requires the lowest resources for the same amount of traffic. But **very likely you do not need it as you cannot get much from it. Sometimes it is used just to enable logging.**

```
set qos policy drop-tail <policy-name> queue-limit <number-of-packets>
```

Use this command to configure a drop-tail policy (PFIFO). Choose a unique name for this policy and the size of the queue by setting the number of packets it can contain (maximum 4294967295).

## Fair Queue

**Queueing discipline:** SFQ (Stochastic Fairness Queueing).

**Applies to:** Outbound traffic.

Fair Queue is a work-conserving scheduler which schedules the transmission of packets based on flows, that is, it balances traffic distributing it through different sub-queues in order to ensure fairness so that each flow is able to send data in turn, preventing any single one from drowning out the rest.

```
set qos policy fair-queue <policy-name>
```

Use this command to create a Fair-Queue policy and give it a name. It is based on the Stochastic Fairness Queueing and can be applied to outbound traffic.

In order to separate traffic, Fair Queue uses a classifier based on source address, destination address and source port. The algorithm enqueues packets to hash buckets based on those three parameters. Each of these buckets should represent a unique flow. Because multiple flows may get hashed to the same bucket, the hashing algorithm is perturbed at configurable intervals so that the unfairness lasts only for a short while. Perturbation may however cause some inadvertent packet reordering to occur. An advisable value could be 10 seconds.

One of the uses of Fair Queue might be the mitigation of Denial of Service attacks.

```
set qos policy fair-queue <policy-name> hash-interval <seconds>
```

Use this command to define a Fair-Queue policy, based on the Stochastic Fairness Queueing, and set the number of seconds at which a new queue algorithm perturbation will occur (maximum 4294967295).

When dequeuing, each hash-bucket with data is queried in a round robin fashion. You can configure the length of the queue.

```
set qos policy fair-queue <policy-name> queue-limit <limit>
```

Use this command to define a Fair-Queue policy, based on the Stochastic Fairness Queueing, and set the number of maximum packets allowed to wait in the queue. Any other packet will be dropped.

---

**Bemerkung:** Fair Queue is a non-shaping (work-conserving) policy, so it will only be useful if your outgoing interface is really full. If it is not, VyOS will not own the queue and Fair Queue will have no effect. If there is bandwidth available on the physical link, you can *embed* Fair-Queue into a classful shaping policy to make sure it owns the queue.

---

## FQ-CoDel

**Queueing discipline** Fair/Flow Queue CoDel.

**Applies to:** Outbound Traffic.

The FQ-CoDel policy distributes the traffic into 1024 FIFO queues and tries to provide good service between all of them. It also tries to keep the length of all the queues short.

FQ-CoDel fights bufferbloat and reduces latency without the need of complex configurations. It has become the new default Queueing Discipline for the interfaces of some GNU/Linux distributions.

It uses a stochastic model to classify incoming packets into different flows and is used to provide a fair share of the bandwidth to all the flows using the queue. Each flow is managed by the CoDel queueing discipline. Reordering within a flow is avoided since CoDel internally uses a FIFO queue.

FQ-CoDel is based on a modified Deficit Round Robin (*DRR*) queue scheduler with the CoDel Active Queue Management (AQM) algorithm operating on each queue.

---

**Bemerkung:** FQ-Codel is a non-shaping (work-conserving) policy, so it will only be useful if your outgoing interface is really full. If it is not, VyOS will not own the queue and FQ-Codel will have no effect. If there is bandwidth available on the physical link, you can *embed* FQ-Codel into a classful shaping policy to make sure it owns the queue. If you are not sure if you need to embed your FQ-CoDel policy into a Shaper, do it.

---

FQ-CoDel is tuned to run ok with its default parameters at 10Gbit speeds. It might work ok too at other speeds without configuring anything, but here we will explain some cases when you might want to tune its parameters.

When running it at 1Gbit and lower, you may want to reduce the *queue-limit* to 1000 packets or less. In rates like 10Mbit, you may want to set it to 600 packets.

If you are using FQ-CoDel embedded into *Shaper* and you have large rates (100Mbit and above), you may consider increasing *quantum* to 8000 or higher so that the scheduler saves CPU.

On low rates (below 40Mbit) you may want to tune *quantum* down to something like 300 bytes.

At very low rates (below 3Mbit), besides tuning *quantum* (300 keeps being ok) you may also want to increase *target* to something like 15ms and increase *interval* to something around 150 ms.

**set qos policy fq-codel <policy name> codel-quantum <bytes>**

Use this command to configure an fq-codel policy, set its name and the maximum number of bytes (default: 1514) to be dequeued from a queue at once.

**set qos policy fq-codel <policy name> flows <number-of-flows>**

Use this command to configure an fq-codel policy, set its name and the number of sub-queues (default: 1024) into which packets are classified.

**set qos policy fq-codel <policy name> interval <milliseconds>**

Use this command to configure an fq-codel policy, set its name and the time period used by the control loop of CoDel to detect when a persistent queue is developing, ensuring that the measured minimum delay does not become too stale (default: 100ms).

**set qos policy fq-codel <policy-name> queue-limit <number-of-packets>**

Use this command to configure an fq-codel policy, set its name, and define a hard limit on the real queue size. When this limit is reached, new packets are dropped (default: 10240 packets).

**set qos policy fq-codel <policy-name> target <milliseconds>**

Use this command to configure an fq-codel policy, set its name, and define the acceptable minimum standing/persistent queue delay. This minimum delay is identified by tracking the local minimum queue delay that packets experience (default: 5ms).

## Example

A simple example of an FQ-CoDel policy working inside a Shaper one.

```
set qos policy shaper FQ-CODEL-SHAPER bandwidth 2gbit
set qos policy shaper FQ-CODEL-SHAPER default bandwidth 100%
set qos policy shaper FQ-CODEL-SHAPER default queue-type fq-codel
```

## Limiter

**Queueing discipline:** Ingress policer.

**Applies to:** Inbound traffic.

Limiter is one of those policies that uses *classes* (Ingress qdisc is actually a classless policy but filters do work in it).

The limiter performs basic ingress policing of traffic flows. Multiple classes of traffic can be defined and traffic limits can be applied to each class. Although the policer uses a token bucket mechanism internally, it does not have the capability to delay a packet as a shaping mechanism does. Traffic exceeding the defined bandwidth limits is directly dropped. A maximum allowed burst can be configured too.

You can configure classes (up to 4090) with different settings and a default policy which will be applied to any traffic not matching any of the configured classes.

---

**Bemerkung:** In the case you want to apply some kind of **shaping** to your **inbound** traffic, check the *ingress-shaping* section.

---

**set qos policy limiter <policy-name> class <class ID> match <match-name> description <description>**

Use this command to configure an Ingress Policer, defining its name, a class identifier (1-4090), a class matching rule name and its description.

Once the matching rules are set for a class, you can start configuring how you want matching traffic to behave.

**set qos policy limiter <policy-name> class <class-ID> bandwidth <rate>**

Use this command to configure an Ingress Policer, defining its name, a class identifier (1-4090) and the maximum allowed bandwidth for this class.

**set qos policy limiter <policy-name> class <class-ID> burst <burst-size>**

Use this command to configure an Ingress Policer, defining its name, a class identifier (1-4090) and the burst size in bytes for this class (default: 15).

**set qos policy limiter <policy-name> default bandwidth <rate>**

Use this command to configure an Ingress Policer, defining its name and the maximum allowed bandwidth for its default policy.

**set qos policy limiter <policy-name> default burst <burst-size>**

Use this command to configure an Ingress Policer, defining its name and the burst size in bytes (default: 15) for its default policy.

**set qos policy limiter <policy-name> class <class ID> priority <value>**

Use this command to configure an Ingress Policer, defining its name, a class identifier (1-4090), and the priority (0-20, default 20) in which the rule is evaluated (the lower the number, the higher the priority).

## Network Emulator

**Queueing discipline:** netem (Network Emulator) + TBF (Token Bucket Filter).

**Applies to:** Outbound traffic.

VyOS Network Emulator policy emulates the conditions you can suffer in a real network. You will be able to configure things like rate, burst, delay, packet loss, packet corruption or packet reordering.

This could be helpful if you want to test how an application behaves under certain network conditions.

**set qos policy network-emulator <policy-name> bandwidth <rate>**

Use this command to configure the maximum rate at which traffic will be shaped in a Network Emulator policy. Define the name of the policy and the rate.

**set qos policy network-emulator <policy-name> burst <burst-size>**

Use this command to configure the burst size of the traffic in a Network Emulator policy. Define the name of the Network Emulator policy and its traffic burst size (it will be configured through the Token Bucket Filter qdisc). Default: 15kb. It will only take effect if you have configured its bandwidth too.

**set qos policy network-emulator <policy-name> delay <delay>**

Use this command to configure a Network Emulator policy defining its name and the fixed amount of time you want to add to all packet going out of the interface. The latency will be added through the Token Bucket Filter qdisc. It will only take effect if you have configured its bandwidth too. You can use secs, ms and us. Default: 50ms.

**set qos policy network-emulator <policy-name> corruption <percent>**

Use this command to emulate noise in a Network Emulator policy. Set the policy name and the percentage of corrupted packets you want. A random error will be introduced in a random position for the chosen percent of packets.

**set qos policy network-emulator <policy-name> loss <percent>**

Use this command to emulate packet-loss conditions in a Network Emulator policy. Set the policy name and the percentage of loss packets your traffic will suffer.

**set traffic-policy network-emulator <policy-name> reordering <percent>**

Use this command to emulate packet-reordering conditions in a Network Emulator policy. Set the policy name and the percentage of reordered packets your traffic will suffer.

**set traffic-policy network-emulator <policy-name> queue-limit <limit>**

Use this command to define the length of the queue of your Network Emulator policy. Set the policy name and the maximum number of packets (1-4294967295) the queue may hold queued at a time.

## Priority Queue

**Queueing discipline:** PRIO.

**Applies to:** Outbound traffic.

The Priority Queue is a classful scheduling policy. It does not delay packets (Priority Queue is not a shaping policy), it simply dequeues packets according to their priority.

---

**Bemerkung:** Priority Queue, as other non-shaping policies, is only useful if your outgoing interface is really full. If it is not, VyOS will not own the queue and Priority Queue will have no effect. If there is bandwidth available on the physical link, you can *embed* Priority Queue into a classful shaping policy to make sure it owns the queue. In that case packets can be prioritized based on DSCP.

---

Up to seven queues -defined as *classes* with different priorities- can be configured. Packets are placed into queues based on associated match criteria. Packets are transmitted from the queues in priority order. If classes with a higher priority are being filled with packets continuously, packets from lower priority classes will only be transmitted after traffic volume from higher priority classes decreases.

---

**Bemerkung:** In Priority Queue we do not define classes with a meaningless class ID number but with a class priority number (1-7). The lower the number, the higher the priority.

---

As with other policies, you can define different type of matching rules for your classes:

```
vyos@vyos# set qos policy priority-queue MY-PRIO class 3 match MY-MATCH-RULE
Possible completions:
  description  Description
> ether        Ethernet header match
  interface    Interface to use
> ip           Match IP protocol header
> ipv6         Match IPV6 protocol header
  mark         Match on mark applied by firewall
  vif          Virtual Local Area Network (VLAN) ID for this match
```

As with other policies, you can *embed* other policies into the classes (and default) of your Priority Queue policy through the queue-type setting:

```
vyos@vyos# set qos policy priority-queue MY-PRIO class 3 queue-type
Possible completions:
  drop-tail      First-In-First-Out (FIFO) (default)
  fq-codel       Fair Queue Codel
  fair-queue     Stochastic Fair Queue (SFQ)
  priority       Priority queueing
  random-detect  Random Early Detection (RED)
```

**set qos policy priority-queue <policy-name> class <class-ID> queue-limit <limit>**

Use this command to configure a Priority Queue policy, set its name, set a class with a priority from 1 to 7 and define a hard limit on the real queue size. When this limit is reached, new packets are dropped.

## Random-Detect

**Queueing discipline:** Generalized Random Early Drop.

**Applies to:** Outbound traffic.

A simple Random Early Detection (RED) policy would start randomly dropping packets from a queue before it reaches its queue limit thus avoiding congestion. That is good for TCP connections as the gradual dropping of packets acts as a signal for the sender to decrease its transmission rate.

In contrast to simple RED, VyOS' Random-Detect uses a Generalized Random Early Detect policy that provides different virtual queues based on the IP Precedence value so that some virtual queues can drop more packets than others.

This is achieved by using the first three bits of the ToS (Type of Service) field to categorize data streams and, in accordance with the defined precedence parameters, a decision is made.

IP precedence as defined in [RFC 791](#):

Precedence	Priority
7	Network Control
6	Internetwork Control
5	CRITIC/ECP
4	Flash Override
3	Flash
2	Immediate
1	Priority
0	Routine

Random-Detect could be useful for heavy traffic. One use of this algorithm might be to prevent a backbone overload. But only for TCP (because dropped packets could be retransmitted), not for UDP.

**set qos policy random-detect <policy-name> bandwidth <bandwidth>**

Use this command to configure a Random-Detect policy, set its name and set the available bandwidth for this policy. It is used for calculating the average queue size after some idle time. It should be set to the bandwidth of your interface. Random Detect is not a shaping policy, this command will not shape.

**set qos policy random-detect <policy-name> precedence <IP-precedence-value>  
average-packet <bytes>**

Use this command to configure a Random-Detect policy and set its name, then state the IP Precedence for the virtual queue you are configuring and what the size of its average-packet should be (in bytes, default: 1024).

---

**Bemerkung:** When configuring a Random-Detect policy: **the higher the precedence number, the higher the priority.**

---

**set qos policy random-detect <policy-name> precedence <IP-precedence-value>  
mark-probability <value>**

Use this command to configure a Random-Detect policy and set its name, then state the IP Precedence for the virtual queue you are configuring and what its mark (drop) probability will be. Set the probability by giving the N value of the fraction 1/N (default: 10).

**set qos policy random-detect <policy-name> precedence <IP-precedence-value>  
maximum-threshold <packets>**

Use this command to configure a Random-Detect policy and set its name, then state the IP Precedence for the virtual queue you are configuring and what its maximum threshold for random detection will be (from 0 to 4096 packets, default: 18). At this size, the marking (drop) probability is maximal.

```
set qos policy random-detect <policy-name> precedence <IP-precedence-value>
minimum-threshold <packets>
```

Use this command to configure a Random-Detect policy and set its name, then state the IP Precedence for the virtual queue you are configuring and what its minimum threshold for random detection will be (from 0 to 4096 packets). If this value is exceeded, packets start being eligible for being dropped.

The default values for the minimum-threshold depend on IP precedence:

Precedence	default min-threshold
7	16
6	15
5	14
4	13
3	12
2	11
1	10
0	9

```
set qos policy random-detect <policy-name> precedence <IP-precedence-value> queue-limit
<packets>
```

Use this command to configure a Random-Detect policy and set its name, then name the IP Precedence for the virtual queue you are configuring and what the maximum size of its queue will be (from 1 to 1-4294967295 packets). Packets are dropped when the current queue length reaches this value.

If the average queue size is lower than the **min-threshold**, an arriving packet will be placed in the queue.

In the case the average queue size is between **min-threshold** and **max-threshold**, then an arriving packet would be either dropped or placed in the queue, it will depend on the defined **mark-probability**.

If the current queue size is larger than **queue-limit**, then packets will be dropped. The average queue size depends on its former average size and its current one.

If **max-threshold** is set but **min-threshold is not**, then **\*\*min-threshold** is scaled to 50% of **max-threshold**.

In principle, values must be **min-threshold < max-threshold < queue-limit**.

## Rate Control

**Queueing discipline:** Token Bucket Filter.

**Applies to:** Outbound traffic.

Rate-Control is a classless policy that limits the packet flow to a set rate. It is a pure shaper, it does not schedule traffic. Traffic is filtered based on the expenditure of tokens. Tokens roughly correspond to bytes.

Short bursts can be allowed to exceed the limit. On creation, the Rate-Control traffic is stocked with tokens which correspond to the amount of traffic that can be burst in one go. Tokens arrive at a steady rate, until the bucket is full.

```
set qos policy rate-control <policy-name> bandwidth <rate>
```

Use this command to configure a Rate-Control policy, set its name and the rate limit you want to have.

**set qos policy rate-control <policy-name> burst <burst-size>**

Use this command to configure a Rate-Control policy, set its name and the size of the bucket in bytes which will be available for burst.

As a reference: for 10mbit/s on Intel, you might need at least 10kbyte buffer if you want to reach your configured rate.

A very small buffer will soon start dropping packets.

**set qos policy rate-control <policy-name> latency**

Use this command to configure a Rate-Control policy, set its name and the maximum amount of time a packet can be queued (default: 50 ms).

Rate-Control is a CPU-friendly policy. You might consider using it when you just simply want to slow traffic down.

**Round Robin**

**Queueing discipline:** Deficit Round Robin.

**Applies to:** Outbound traffic.

The round-robin policy is a classful scheduler that divides traffic in different *classes* you can configure (up to 4096). You can *embed* a new policy into each of those classes (default included).

Each class is assigned a deficit counter (the number of bytes that a flow is allowed to transmit when it is its turn) initialized to quantum. Quantum is a parameter you configure which acts like a credit of fix bytes the counter receives on each round. Then the Round-Robin policy starts moving its Round Robin pointer through the queues. If the deficit counter is greater than the packet's size at the head of the queue, this packet will be sent and the value of the counter will be decremented by the packet size. Then, the size of the next packet will be compared to the counter value again, repeating the process. Once the queue is empty or the value of the counter is insufficient, the Round-Robin pointer will move to the next queue. If the queue is empty, the value of the deficit counter is reset to 0.

At every round, the deficit counter adds the quantum so that even large packets will have their opportunity to be de-queued.

**set qos policy round-robin <policy name> class <class-ID> quantum <packets>**

Use this command to configure a Round-Robin policy, set its name, set a class ID, and the quantum for that class. The deficit counter will add that value each round.

**set qos policy round-robin <policy name> class <class ID> queue-limit <packets>**

Use this command to configure a Round-Robin policy, set its name, set a class ID, and the queue size in packets.

As with other policies, Round-Robin can *embed* another policy into a class through the `queue-type` setting.

```
vyos@vyos# set qos policy round-robin DRR class 10 queue-type
```

Possible completions:

drop-tail	First-In-First-Out (FIFO) (default)
fq-codel	Fair Queue Codel
fair-queue	Stochastic Fair Queue (SFQ)
priority	Priority queueing based
random-detect	Random Early Detection (RED)

## Shaper

**Queueing discipline:** Hierarchical Token Bucket.

**Applies to:** Outbound traffic.

The Shaper policy does not guarantee a low delay, but it does guarantee bandwidth to different traffic classes and also lets you decide how to allocate more traffic once the guarantees are met.

Each class can have a guaranteed part of the total bandwidth defined for the whole policy, so all those shares together should not be higher than the policy's whole bandwidth.

If guaranteed traffic for a class is met and there is room for more traffic, the ceiling parameter can be used to set how much more bandwidth could be used. If guaranteed traffic is met and there are several classes willing to use their ceilings, the priority parameter will establish the order in which that additional traffic will be allocated. Priority can be any number from 0 to 7. The lower the number, the higher the priority.

**set qos policy shaper <policy-name> bandwidth <rate>**

Use this command to configure a Shaper policy, set its name and the maximum bandwidth for all combined traffic.

**set qos policy shaper <policy-name> class <class-ID> bandwidth <rate>**

Use this command to configure a Shaper policy, set its name, define a class and set the guaranteed traffic you want to allocate to that class.

**set qos policy shaper <policy-name> class <class-ID> burst <bytes>**

Use this command to configure a Shaper policy, set its name, define a class and set the size of the [token bucket](#) in bytes, which will be available to be sent at ceiling speed (default: 15Kb).

**set qos policy shaper <policy-name> class <class-ID> ceiling <bandwidth>**

Use this command to configure a Shaper policy, set its name, define a class and set the maximum speed possible for this class. The default ceiling value is the bandwidth value.

**set qos policy shaper <policy-name> class <class-ID> priority <0-7>**

Use this command to configure a Shaper policy, set its name, define a class and set the priority for usage of available bandwidth once guarantees have been met. The lower the priority number, the higher the priority. The default priority value is 0, the highest priority.

As with other policies, Shaper can [embed](#) other policies into its classes through the queue-type setting and then configure their parameters.

```
vyos@vyos# set qos policy shaper HTB class 10 queue-type
```

Possible completions:

fq-codel	Fair Queue Codel (default)
fair-queue	Stochastic Fair Queue (SFQ)
drop-tail	First-In-First-Out (FIFO)
priority	Priority queueing
random-detect	Random Early Detection (RED)

```
vyos@vyos# set qos policy shaper HTB class 10
```

Possible completions:

bandwidth	Available bandwidth for this policy (default: auto)
burst	Burst size for this class (default: 15k)

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

ceiling	Bandwidth limit for this class
codel-quantum	Deficit in the fair queuing algorithm (default 1514)
description	Description
flows	Number of flows into which the incoming packets are classified (default ↵ ↵ 1024)
interval	Interval used to measure the delay (default 100)
+> match	Class matching rule name
priority	Priority for rule evaluation
queue-limit	Maximum queue size (packets)
queue-type	Queue type for default traffic (default: fq-codel)
set-dscp	Change the Differentiated Services (DiffServ) field in the IP header
target	Acceptable minimum standing/persistent queue delay (default: 5)

**Bemerkung:** If you configure a class for **VoIP traffic**, don't give it any *ceiling*, otherwise new VoIP calls could start when the link is available and get suddenly dropped when other classes start using their assigned *bandwidth* share.

## Example

A simple example of Shaper using priorities.

```
set qos policy shaper MY-HTB bandwidth '50mbit'
set qos policy shaper MY-HTB class 10 bandwidth '20%'
set qos policy shaper MY-HTB class 10 match DSCP ip dscp 'EF'
set qos policy shaper MY-HTB class 10 queue-type 'fq-codel'
set qos policy shaper MY-HTB class 20 bandwidth '10%'
set qos policy shaper MY-HTB class 20 ceiling '50%'
set qos policy shaper MY-HTB class 20 match PORT666 ip destination port '666'
set qos policy shaper MY-HTB class 20 priority '3'
set qos policy shaper MY-HTB class 20 queue-type 'fair-queue'
set qos policy shaper MY-HTB class 30 bandwidth '10%'
set qos policy shaper MY-HTB class 30 ceiling '50%'
set qos policy shaper MY-HTB class 30 match ADDRESS30 ip source address '192.168.30.0/24'
set qos policy shaper MY-HTB class 30 priority '5'
set qos policy shaper MY-HTB class 30 queue-type 'fair-queue'
set qos policy shaper MY-HTB default bandwidth '10%'
set qos policy shaper MY-HTB default ceiling '100%'
set qos policy shaper MY-HTB default priority '7'
set qos policy shaper MY-HTB default queue-type 'fair-queue'
```

## CAKE

**Queueing discipline:** Deficit mode.

**Applies to:** Outbound traffic.

**Common Applications Kept Enhanced** (CAKE) is a comprehensive queue management system, implemented as a queue discipline (qdisc) for the Linux kernel. It is designed to replace and improve upon the complex hierarchy of simple qdiscs presently required to effectively tackle the bufferbloat problem at the network edge.

**set qos policy cake <text> bandwidth <value>**

Set the shaper bandwidth, either as an explicit bitrate or a percentage of the interface bandwidth.

**set qos policy cake <text> description**

Set a description for the shaper.

**set qos policy cake <text> flow-isolation blind**

Disables flow isolation, all traffic passes through a single queue.

**set qos policy cake <text> flow-isolation dst-host**

Flows are defined only by destination address.

**set qos policy cake <text> flow-isolation dual-dst-host**

Flows are defined by the 5-tuple. Fairness is applied first over destination addresses, then over individual flows.

**set qos policy cake <text> flow-isolation dual-src-host**

Flows are defined by the 5-tuple. Fairness is applied first over source addresses, then over individual flows.

**set qos policy cake <text> flow-isolation flow**

Flows are defined by the entire 5-tuple (source IP address, source port, destination IP address, destination port, transport protocol).

**set qos policy cake <text> flow-isolation host**

Flows are defined by source-destination host pairs.

**set qos policy cake <text> flow-isolation nat**

Perform NAT lookup before applying flow-isolation rules.

**set qos policy cake <text> flow-isolation src-host**

Flows are defined only by source address.

**set qos policy cake <text> flow-isolation triple-isolate**

**(Default)** Flows are defined by the 5-tuple, fairness is applied over source and destination addresses and also over individual flows.

**set qos policy cake <text> rtt**

Defines the round-trip time used for active queue management (AQM) in milliseconds. The default value is 100.

## Applying a traffic policy

Once a traffic-policy is created, you can apply it to an interface:

```
set qos interface eth0 egress WAN-OUT
```

You can only apply one policy per interface and direction, but you could reuse a policy on different interfaces and directions:

```
set qos interface eth0 ingress WAN-IN
set qos interface eth0 egress WAN-OUT
set qos interface eth1 ingress LAN-IN
set qos interface eth1 egress LAN-OUT
set qos interface eth2 ingress LAN-IN
set qos interface eth2 egress LAN-OUT
set qos interface eth3 ingress TWO-WAY-POLICY
set qos interface eth3 egress TWO-WAY-POLICY
set qos interface eth4 ingress TWO-WAY-POLICY
set qos interface eth4 egress TWO-WAY-POLICY
```

## The case of ingress shaping

**Applies to:** Inbound traffic.

For the ingress traffic of an interface, there is only one policy you can directly apply, a **Limiter** policy. You cannot apply a shaping policy directly to the ingress traffic of any interface because shaping only works for outbound traffic.

This workaround lets you apply a shaping policy to the ingress traffic by first redirecting it to an in-between virtual interface ([Intermediate Functional Block](#)). There, in that virtual interface, you will be able to apply any of the policies that work for outbound traffic, for instance, a shaping one.

That is how it is possible to do the so-called „ingress shaping“.

```
set qos policy shaper MY-INGRESS-SHAPING bandwidth 1000kbit
set qos policy shaper MY-INGRESS-SHAPING default bandwidth 1000kbit
set qos policy shaper MY-INGRESS-SHAPING default queue-type fair-queue

set qos interface ifb0 egress MY-INGRESS-SHAPING
set interfaces ethernet eth0 redirect ifb0

set interfaces input ifb0
```

**Warnung:** Do not configure IFB as the first step. First create everything else of your traffic-policy, and then you can configure IFB. Otherwise you might get the RTNETLINK answer: File exists error, which can be solved with `sudo ip link delete ifb0`.

## 8.13 VPN

### 8.13.1 IPsec

GRE (Generic Routing Encapsulation), GRE/IPsec (or IPsec/IPsec, SIT/IPsec, or any other stateless tunnel protocol over IPsec) is the usual way to protect the traffic inside a tunnel.

An advantage of this scheme is that you get a real interface with its own address, which makes it easier to setup static routes or use dynamic routing protocols without having to modify IPsec policies. The other advantage is that it greatly simplifies router to router communication, which can be tricky with plain IPsec because the external outgoing address of the router usually doesn't match the IPsec policy of typical site-to-site setup and you need to add special configuration for it, or adjust the source address for outgoing traffic of your applications. GRE/IPsec has no such problem and is completely transparent for the applications.

GRE/IPsec and IPsec are widely accepted standards, which make this scheme easy to implement between VyOS and virtually any other router.

For simplicity we'll assume that the protocol is GRE, it's not hard to guess what needs to be changed to make it work with a different protocol. We assume that IPsec will use pre-shared secret authentication and will use AES128/SHA1 for the cipher and hash. Adjust this as necessary.

---

**Bemerkung:** VMware users should ensure that a VMXNET3 adapter is used. E1000 adapters have known issues with GRE processing.

---

### IKE (Internet Key Exchange) Attributes

IKE performs mutual authentication between two parties and establishes an IKE security association (SA) that includes shared secret information that can be used to efficiently establish SAs for Encapsulating Security Payload (ESP) or Authentication Header (AH) and a set of cryptographic algorithms to be used by the SAs to protect the traffic that they carry. <https://datatracker.ietf.org/doc/html/rfc5996>

In VyOS, IKE attributes are specified through IKE groups. Multiple proposals can be specified in a single group.

VyOS IKE group has the next options:

- `close-action` defines the action to take if the remote peer unexpectedly closes a CHILD\_SA;
- `none` set action to none (default);
- `trap` installs a trap policy for the CHILD\_SA;
- `start` tries to immediately re-create the CHILD\_SA;
- `dead-peer-detection` controls the use of the Dead Peer Detection protocol (DPD, RFC 3706) where R\_U\_THERE notification messages (IKEv1) or empty INFORMATIONAL messages (IKEv2) are periodically sent in order to check the liveliness of the IPsec peer:
  - `action` keep-alive failure action:
  - `trap` installs a trap policy, which will catch matching traffic and tries to re-negotiate the tunnel on-demand;
  - `clear` closes the CHILD\_SA and does not take further action (default);
  - `restart` immediately tries to re-negotiate the CHILD\_SA under a fresh IKE\_SA;
  - `interval` keep-alive interval in seconds <2-86400> (default 30);
  - `timeout` keep-alive timeout in seconds <2-86400> (default 120) IKEv1 only

- `ikev2-reauth` whether rekeying of an IKE\_SA should also reauthenticate the peer. In IKEv1, reauthentication is always done. Setting this parameter enables remote host re-authentication during an IKE rekey.
- `key-exchange` which protocol should be used to initialize the connection If not set both protocols are handled and connections will use IKEv2 when initiating, but accept any protocol version when responding:
- `ikev1` use IKEv1 for Key Exchange;
- `ikev2` use IKEv2 for Key Exchange;
- `lifetime` IKE lifetime in seconds <0-86400> (default 28800);
- `disable-mobike` disables MOBIKE Support. MOBIKE is only available for IKEv2 and enabled by default.
- `mode` IKEv1 Phase 1 Mode Selection:
- `main` use Main mode for Key Exchanges in the IKEv1 Protocol (Recommended Default);
- `aggressive` use Aggressive mode for Key Exchanges in the IKEv1 protocol aggressive mode is much more insecure compared to Main mode;
- `proposal` the list of proposals and their parameters:
- `dh-group` dh-group;
- `encryption` encryption algorithm;
- `hash` hash algorithm.
- `prf` pseudo-random function.

### ESP (Encapsulating Security Payload) Attributes

ESP is used to provide confidentiality, data origin authentication, connectionless integrity, an anti-replay service (a form of partial sequence integrity), and limited traffic flow confidentiality. <https://datatracker.ietf.org/doc/html/rfc4303>

In VyOS, ESP attributes are specified through ESP groups. Multiple proposals can be specified in a single group.

VyOS ESP group has the next options:

- `compression` Enables the IPComp(IP Payload Compression) protocol which allows compressing the content of IP packets.
- `life-bytes` ESP life in bytes <1024-26843545600000>. Number of bytes transmitted over an IPsec SA before it expires;
- `life-packets` ESP life in packets <1000-26843545600000>. Number of packets transmitted over an IPsec SA before it expires;
- `lifetime` ESP lifetime in seconds <30-86400> (default 3600). How long a particular instance of a connection (a set of encryption/authentication keys for user packets) should last, from successful negotiation to expiry;
- `mode` the type of the connection:
- `tunnel` tunnel mode (default);
- `transport` transport mode;
- `pfs` whether Perfect Forward Secrecy of keys is desired on the connection's keying channel and defines a Diffie-Hellman group for PFS;
- `enable` Inherit Diffie-Hellman group from IKE group (default);
- `disable` Disable PFS;
- `< dh-group >` defines a Diffie-Hellman group for PFS;

- proposal ESP-group proposal with number <1-65535>;
- encryption encryption algorithm (default 128 bit AES-CBC);
- hash hash algorithm (default sha1).

### Options (Global IPsec settings) Attributes

- options
- disable-route-autoinstall Do not automatically install routes to remote networks;
- flexvpn Allows FlexVPN vendor ID payload (IKEv2 only). Send the Cisco FlexVPN vendor ID payload (IKEv2 only), which is required in order to make Cisco brand devices allow negotiating a local traffic selector (from strongSwan's point of view) that is not the assigned virtual IP address if such an address is requested by strongSwan. Sending the Cisco FlexVPN vendor ID prevents the peer from narrowing the initiator's local traffic selector and allows it to e.g. negotiate a TS of 0.0.0.0/0 == 0.0.0.0/0 instead. This has been tested with a „tunnel mode ipsec ipv4“ Cisco template but should also work for GRE encapsulation;
- interface Interface Name to use. The name of the interface on which virtual IP addresses should be installed. If not specified the addresses will be installed on the outbound interface;
- virtual-ip Allows to install virtual-ip addresses. Comma separated list of virtual IPs to request in IKEv2 configuration payloads or IKEv1 Mode Config. The wildcard addresses 0.0.0.0 and :: request an arbitrary address, specific addresses may be defined. The responder may return a different address, though, or none at all. Define the virtual-address option to configure the IP address in site-to-site hierarchy.

### IPsec policy matching GRE

The first and arguably cleaner option is to make your IPsec policy match GRE packets between external addresses of your routers. This is the best option if both routers have static external addresses.

Suppose the LEFT router has external address 192.0.2.10 on its eth0 interface, and the RIGHT router is 203.0.113.45

On the LEFT:

```
# GRE tunnel
set interfaces tunnel tun0 encapsulation gre
set interfaces tunnel tun0 source-address 192.0.2.10
set interfaces tunnel tun0 remote 203.0.113.45
set interfaces tunnel tun0 address 10.10.10.1/30

## IPsec
set vpn ipsec interface eth0

# Pre-shared-secret
set vpn ipsec authentication psk vyos id 192.0.2.10
set vpn ipsec authentication psk vyos id 203.0.113.45
set vpn ipsec authentication psk vyos secret MYSECRETKEY

# IKE group
set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group '2'
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption 'aes128'
set vpn ipsec ike-group MyIKEGroup proposal 1 hash 'sha1'

# ESP group
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set vpn ipsec esp-group MyESPGroup proposal 1 encryption 'aes128'
set vpn ipsec esp-group MyESPGroup proposal 1 hash 'sha1'

# IPsec tunnel
set vpn ipsec site-to-site peer right authentication mode pre-shared-secret
set vpn ipsec site-to-site peer right authentication remote-id 203.0.113.45

set vpn ipsec site-to-site peer right ike-group MyIKEGroup
set vpn ipsec site-to-site peer right default-esp-group MyESPGroup

set vpn ipsec site-to-site peer right local-address 192.0.2.10
set vpn ipsec site-to-site peer right remote-address 203.0.113.45

# This will match all GRE traffic to the peer
set vpn ipsec site-to-site peer right tunnel 1 protocol gre

```

On the RIGHT, setup by analogy and swap local and remote addresses.

### Source tunnel from dummy interface

The scheme above doesn't work when one of the routers has a dynamic external address though. The classic workaround for this is to setup an address on a loopback interface and use it as a source address for the GRE tunnel, then setup an IPsec policy to match those loopback addresses.

We assume that the LEFT router has static 192.0.2.10 address on eth0, and the RIGHT router has a dynamic address on eth0.

The peer names RIGHT and LEFT are used as informational text.

### Setting up the GRE tunnel

On the LEFT:

```

set interfaces dummy dum0 address 192.168.99.1/32

set interfaces tunnel tun0 encapsulation gre
set interfaces tunnel tun0 address 10.10.10.1/30
set interfaces tunnel tun0 source-address 192.168.99.1
set interfaces tunnel tun0 remote 192.168.99.2

```

On the RIGHT:

```

set interfaces dummy dum0 address 192.168.99.2/32

set interfaces tunnel tun0 encapsulation gre
set interfaces tunnel tun0 address 10.10.10.2/30
set interfaces tunnel tun0 source-address 192.168.99.2
set interfaces tunnel tun0 remote 192.168.99.1

```

### Setting up IPsec

However, now you need to make IPsec work with dynamic address on one side. The tricky part is that pre-shared secret authentication doesn't work with dynamic address, so we'll have to use RSA keys.

First, on both routers run the operational command „generate pki key-pair install <key-pair name>“. You may choose different length than 2048 of course.

```
vyos@left# run generate pki key-pair install ipsec-LEFT
Enter private key type: [rsa, dsa, ec] (Default: rsa)
Enter private key bits: (Default: 2048)
Note: If you plan to use the generated key on this router, do not encrypt the private_
key.
Do you want to encrypt the private key with a passphrase? [y/N] N
Configure mode commands to install key pair:
Do you want to install the public key? [Y/n] Y
set pki key-pair ipsec-LEFT public key 'MIIBIjANBgkqh...'
Do you want to install the private key? [Y/n] Y
set pki key-pair ipsec-LEFT private key 'MIIEvgIBADAN...'
[edit]
```

Configuration commands for the private and public key will be displayed on the screen which needs to be set on the router first. Note the command with the public key (set pki key-pair ipsec-LEFT public key ,MIIBIjANBgkqh...'). Then do the same on the opposite router:

```
vyos@left# run generate pki key-pair install ipsec-RIGHT
```

Note the command with the public key (set pki key-pair ipsec-RIGHT public key ,FAAOCAQ8AMII...').

Now the noted public keys should be entered on the opposite routers.

On the LEFT:

```
set pki key-pair ipsec-RIGHT public key 'FAAOCAQ8AMII...'
```

On the RIGHT:

```
set pki key-pair ipsec-LEFT public key 'MIIBIjANBgkqh...'
```

Now you are ready to setup IPsec. You'll need to use an ID instead of address for the peer.

On the LEFT (static address):

```
set vpn ipsec interface eth0

set vpn ipsec esp-group MyESPGroup proposal 1 encryption aes128
set vpn ipsec esp-group MyESPGroup proposal 1 hash sha1

set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group 2
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption aes128
set vpn ipsec ike-group MyIKEGroup proposal 1 hash sha1

set vpn ipsec site-to-site peer RIGHT authentication local-id LEFT
set vpn ipsec site-to-site peer RIGHT authentication mode rsa
set vpn ipsec site-to-site peer RIGHT authentication rsa local-key ipsec-LEFT
set vpn ipsec site-to-site peer RIGHT authentication rsa remote-key ipsec-RIGHT
set vpn ipsec site-to-site peer RIGHT authentication remote-id RIGHT
set vpn ipsec site-to-site peer RIGHT default-esp-group MyESPGroup
set vpn ipsec site-to-site peer RIGHT ike-group MyIKEGroup
set vpn ipsec site-to-site peer RIGHT local-address 192.0.2.10
set vpn ipsec site-to-site peer RIGHT connection-type respond
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set vpn ipsec site-to-site peer RIGHT tunnel 1 local prefix 192.168.99.1/32 #
↳ Additional loopback address on the local
set vpn ipsec site-to-site peer RIGHT tunnel 1 remote prefix 192.168.99.2/32 #
↳ Additional loopback address on the remote
```

On the RIGHT (dynamic address):

```
set vpn ipsec interface eth0

set vpn ipsec esp-group MyESPGroup proposal 1 encryption aes128
set vpn ipsec esp-group MyESPGroup proposal 1 hash sha1

set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group 2
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption aes128
set vpn ipsec ike-group MyIKEGroup proposal 1 hash sha1

set vpn ipsec site-to-site peer LEFT authentication local-id RIGHT
set vpn ipsec site-to-site peer LEFT authentication mode rsa
set vpn ipsec site-to-site peer LEFT authentication rsa local-key ipsec-RIGHT
set vpn ipsec site-to-site peer LEFT authentication rsa remote-key ipsec-LEFT
set vpn ipsec site-to-site peer LEFT authentication remote-id LEFT
set vpn ipsec site-to-site peer LEFT connection-type initiate
set vpn ipsec site-to-site peer LEFT default-esp-group MyESPGroup
set vpn ipsec site-to-site peer LEFT ike-group MyIKEGroup
set vpn ipsec site-to-site peer LEFT local-address any
set vpn ipsec site-to-site peer LEFT remote-address 192.0.2.10
set vpn ipsec site-to-site peer LEFT tunnel 1 local prefix 192.168.99.2/32 # Additional
↳ loopback address on the local
set vpn ipsec site-to-site peer LEFT tunnel 1 remote prefix 192.168.99.1/32 # Additional
↳ loopback address on the remote
```

## IKEv2 IPsec road-warriors remote-access VPN

Internet Key Exchange version 2, IKEv2 for short, is a request/response protocol developed by both Cisco and Microsoft. It is used to establish and secure IPv4/IPv6 connections, be it a site-to-site VPN or from a road-warrior connecting to a hub site. IKEv2, when run in point-to-multipoint, or remote-access/road-warrior mode, secures the server-side with another layer by using an x509 signed server certificate.

Key exchange and payload encryption is still done using IKE and ESP proposals as known from IKEv1 but the connections are faster to establish, more reliable, and also support roaming from IP to IP (called MOBIKE which makes sure your connection does not drop when changing networks from e.g. WIFI to LTE and back).

This feature closely works together with *PKI* subsystem as you required a x509 certificate.

This example uses CACert as certificate authority.

```
set pki ca CACert_Class_3_Root certificate
↳ 'MIIGPTCCBCWgAwIBAgIDF0IoMA0GCSqGSIb3DQEBAQUAMHkxEDA0BgNVBAoTB1Jvb3QgQ0ExHjAcBgNVBAsTFWh0dHA6Ly93d3cu

→ '

```

After you obtained your server certificate you can import it from a file on the local filesystem, or paste it into the CLI. Please note that when entering the certificate manually you need to strip the -----BEGIN KEY----- and -----END KEY----- tags. Also, the certificate or key needs to be presented in a single line without line breaks (\n).

To import it from the filesystem use:

```
import pki certificate <name> file /path/to/cert.pem
```

In our example the certificate name is called vyos:

```
set pki certificate vyos certificate 'MIIE45s...'
set pki certificate vyos private key 'MIIEvgI...'
```

After the PKI certs are all set up we can start configuring our IPSec/IKE proposals used for key-exchange end data encryption. The used encryption ciphers and integrity algorithms vary from operating system to operating system. The ones used in this post are validated to work on both Windows 10 and iOS/iPadOS 14 to 17.

```
set vpn ipsec esp-group ESP-RW compression 'disable'
set vpn ipsec esp-group ESP-RW lifetime '3600'
set vpn ipsec esp-group ESP-RW pfs 'disable'
set vpn ipsec esp-group ESP-RW proposal 10 encryption 'aes128gcm128'
set vpn ipsec esp-group ESP-RW proposal 10 hash 'sha256'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set vpn ipsec ike-group IKE-RW key-exchange 'ikev2'
set vpn ipsec ike-group IKE-RW lifetime '7200'
set vpn ipsec ike-group IKE-RW mobike 'enable'
set vpn ipsec ike-group IKE-RW proposal 10 dh-group '14'
set vpn ipsec ike-group IKE-RW proposal 10 encryption 'aes128gcm128'
set vpn ipsec ike-group IKE-RW proposal 10 hash 'sha256'

```

Every connection/remote-access pool we configure also needs a pool where we can draw our client IP addresses from. We provide one IPv4 and IPv6 pool. Authorized clients will receive an IPv4 address from the 192.0.2.128/25 prefix and an IPv6 address from the 2001:db8:2000::/64 prefix. We can also send some DNS nameservers down to our clients used on their connection.

```

set vpn ipsec remote-access pool ra-rw-ipv4 name-server '192.0.2.1'
set vpn ipsec remote-access pool ra-rw-ipv4 prefix '192.0.2.128/25'
set vpn ipsec remote-access pool ra-rw-ipv6 name-server '2001:db8:1000::1'
set vpn ipsec remote-access pool ra-rw-ipv6 prefix '2001:db8:2000::/64'

```

VyOS supports multiple IKEv2 remote-access connections. Every connection can have its dedicated IKE/ESP ciphers, certificates or local listen address for e.g. inbound load balancing.

We configure a new connection named `rw` for road-warrior, that identifies itself as 192.0.2.1 to the clients and uses the `vyos` certificate signed by the `CAcert_Class3_Root` intermediate CA. We select our previously specified IKE/ESP groups and also link the IP address pool to draw addresses from.

```

set vpn ipsec remote-access connection rw authentication id '192.0.2.1'
set vpn ipsec remote-access connection rw authentication server-mode 'x509'
set vpn ipsec remote-access connection rw authentication x509 ca-certificate 'CAcert_
↳Class3_Root'
set vpn ipsec remote-access connection rw authentication x509 certificate 'vyos'
set vpn ipsec remote-access connection rw esp-group 'ESP-RW'
set vpn ipsec remote-access connection rw ike-group 'IKE-RW'
set vpn ipsec remote-access connection rw local-address '192.0.2.1'
set vpn ipsec remote-access connection rw pool 'ra-rw-ipv4'
set vpn ipsec remote-access connection rw pool 'ra-rw-ipv6'

```

VyOS also supports (currently) two different modes of authentication, local and RADIUS. To create a new local user named `vyos` with password `vyos` use the following commands.

```

set vpn ipsec remote-access connection rw authentication client-mode 'eap-mschap2'
set vpn ipsec remote-access connection rw authentication local-users username vyos_
↳password 'vyos'

```

If you feel better forwarding all authentication requests to your enterprises RADIUS server, use the commands below.

```

set vpn ipsec remote-access connection rw authentication client-mode 'eap-radius'
set vpn ipsec remote-access radius server 192.0.2.2 key 'secret'

```

Configuring VyOS to act as your IPSec access concentrator is one thing, but you probably need to setup your client connecting to the server so they can talk to the IPSec gateway.

Windows 10 does not allow a user to choose the integrity and encryption ciphers using the GUI and it uses some older proposals by default. A user can only change the proposals on the client side by configuring the IPSec connection profile via PowerShell.

We generate a connection profile used by Windows clients that will connect to the „rw“ connection on our VyOS server on the VPN servers IP address/fqdn *vpn.vyos.net*.

**Bemerkung:** Microsoft Windows expects the server name to be also used in the server's certificate common name, so it's best to use this DNS name for your VPN connection.

```
vyos@vyos:~$ generate ipsec profile windows-remote-access rw remote vpn.vyos.net

==== <snip> ====
Add-VpnConnection -Name "VyOS IKEv2 VPN" -ServerAddress "vpn.vyos.net" -TunnelType
↪ "Ikev2"
Set-VpnConnectionIPsecConfiguration -ConnectionName "VyOS IKEv2 VPN" -
↪ AuthenticationTransformConstants GCMAES128 -CipherTransformConstants GCMAES128 -
↪ EncryptionMethod GCMAES128 -IntegrityCheckMethod SHA256128 -PfsGroup None -DHGroup
↪ "Group14" -PassThru -Force
==== </snip> ====
```

As both Microsoft Windows and Apple iOS/iPadOS only support a certain set of encryption ciphers and integrity algorithms we will validate the configured IKE/ESP proposals and only list the compatible ones to the user — if multiple are defined. If there are no matching proposals found — we can not generate a profile for you.

When first connecting to the new VPN the user is prompted to enter proper credentials.

Like on Microsoft Windows, Apple iOS/iPadOS out of the box does not expose all available VPN options via the device GUI.

If you want, need, and should use more advanced encryption ciphers (default is still 3DES) you need to provision your device using a so-called „Device Profile“. A profile is a simple text file containing XML nodes with a *.mobileconfig* file extension that can be sent and opened on any device from an E-Mail.

Profile generation happens from the operational level and is as simple as issuing the following command to create a profile to connect to the IKEv2 access server at *vpn.vyos.net* with the configuration for the *rw* remote-access connection group.

**Bemerkung:** Apple iOS/iPadOS expects the server name to be also used in the server's certificate common name, so it's best to use this DNS name for your VPN connection.

```
vyos@vyos:~$ generate ipsec profile ios-remote-access rw remote vpn.vyos.net

==== <snip> ====
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/
↪ PropertyList-1.0.dtd">
<plist version="1.0">
...
</plist>
==== </snip> ====
```

In the end, an XML structure is generated which can be saved as *vyos.mobileconfig* and sent to the device by E-Mail where it later can be imported.

During profile import, the user is asked to enter its IPSec credentials (username and password) which is stored on the mobile.

### 8.13.2 L2TP

VyOS utilizes `accel-ppp` to provide L2TP server functionality. It can be used with local authentication or a connected RADIUS server.

#### Configuring L2TP Server

```
set vpn l2tp remote-access authentication mode local
set vpn l2tp remote-access authentication local-users username test password 'test'
set vpn l2tp remote-access client-ip-pool L2TP-POOL range 192.168.255.2-192.168.255.254
set vpn l2tp remote-access default-pool 'L2TP-POOL'
set vpn l2tp remote-access outside-address 192.0.2.2
set vpn l2tp remote-access gateway-address 192.168.255.1
```

**set vpn l2tp remote-access authentication mode <local | radius>**

Set authentication backend. The configured authentication backend is used for all queries.

- **radius:** All authentication queries are handled by a configured RADIUS server.
- **local:** All authentication queries are handled locally.

**set vpn l2tp remote-access authentication local-users username <user> password <pass>**

Create <user> for local authentication on this system. The users password will be set to <pass>.

**set vpn l2tp remote-access client-ip-pool <POOL-NAME> range <x.x.x.x-x.x.x.x | x.x.x.x/x>**

Use this command to define the first IP address of a pool of addresses to be given to l2tp clients. If notation `x.x.x.x-x.x.x.x`, it must be within a /24 subnet. If notation `x.x.x.x/x` is used there is possibility to set host/netmask.

**set vpn l2tp remote-access default-pool <POOL-NAME>**

Use this command to define default address pool name.

**set vpn l2tp remote-access gateway-address <gateway>**

Specifies single <gateway> IP address to be used as local address of PPP interfaces.

#### Configuring IPsec

```
set vpn ipsec interface eth0
set vpn l2tp remote-access ipsec-settings authentication mode pre-shared-secret
set vpn l2tp remote-access ipsec-settings authentication pre-shared-secret <secret>
```

**set vpn ipsec interface <INTERFACE>**

Use this command to define IPsec interface.

**set vpn l2tp remote-access ipsec-settings authentication mode <pre-shared-secret | x509>**

Set mode for IPsec authentication between VyOS and L2TP clients.

**set vpn l2tp remote-access ipsec-settings authentication mode <pre-shared-secret | x509>**

Set predefined shared secret phrase.

If a local firewall policy is in place on your external interface you will need to allow the ports below:

- UDP port 500 (IKE)

- IP protocol number 50 (ESP)
- UDP port 1701 for IPsec

As well as the below to allow NAT-traversal (when NAT is detected by the VPN client, ESP is encapsulated in UDP for NAT-traversal):

- UDP port 4500 (NAT-T)

Example:

```
set firewall name OUTSIDE-LOCAL rule 40 action 'accept'
set firewall name OUTSIDE-LOCAL rule 40 protocol 'esp'
set firewall name OUTSIDE-LOCAL rule 41 action 'accept'
set firewall name OUTSIDE-LOCAL rule 41 destination port '500'
set firewall name OUTSIDE-LOCAL rule 41 protocol 'udp'
set firewall name OUTSIDE-LOCAL rule 42 action 'accept'
set firewall name OUTSIDE-LOCAL rule 42 destination port '4500'
set firewall name OUTSIDE-LOCAL rule 42 protocol 'udp'
set firewall name OUTSIDE-LOCAL rule 43 action 'accept'
set firewall name OUTSIDE-LOCAL rule 43 destination port '1701'
set firewall name OUTSIDE-LOCAL rule 43 ipsec 'match-ipsec'
set firewall name OUTSIDE-LOCAL rule 43 protocol 'udp'
```

To allow VPN-clients access via your external address, a NAT rule is required:

```
set nat source rule 110 outbound-interface name 'eth0'
set nat source rule 110 source address '192.168.255.0/24'
set nat source rule 110 translation address masquerade
```

## Configuring RADIUS authentication

To enable RADIUS based authentication, the authentication mode needs to be changed within the configuration. Previous settings like the local users, still exists within the configuration, however they are not used if the mode has been changed from local to radius. Once changed back to local, it will use all local accounts again.

```
set vpn l2tp remote-access authentication mode radius
```

```
set vpn l2tp remote-access authentication radius server <server> key <secret>
```

Configure RADIUS <server> and its required shared <secret> for communicating with the RADIUS server.

Since the RADIUS server would be a single point of failure, multiple RADIUS servers can be setup and will be used subsequently. For example:

```
set vpn l2tp remote-access authentication radius server 10.0.0.1 key 'foo'
set vpn l2tp remote-access authentication radius server 10.0.0.2 key 'foo'
```

---

**Bemerkung:** Some RADIUS servers use an access control list which allows or denies queries, make sure to add your VyOS router to the allowed client list.

---

## RADIUS source address

If you are using OSPF as IGP, always the closest interface connected to the RADIUS server is used. With VyOS 1.2 you can bind all outgoing RADIUS requests to a single source IP e.g. the loopback interface.

```
set vpn l2tp remote-access authentication radius source-address <address>
```

Source IPv4 address used in all RADIUS server queries.

---

**Bemerkung:** The source-address must be configured on one of VyOS interface. Best practice would be a loopback or dummy interface.

---

## RADIUS advanced options

```
set vpn l2tp remote-access authentication radius server <server> port <port>
```

Configure RADIUS <server> and its required port for authentication requests.

```
set vpn l2tp remote-access authentication radius server <server> fail-time <time>
```

Mark RADIUS server as offline for this given <time> in seconds.

```
set vpn l2tp remote-access authentication radius server <server> disable
```

Temporary disable this RADIUS server.

```
set vpn l2tp remote-access authentication radius acct-timeout <timeout>
```

Timeout to wait reply for Interim-Update packets. (default 3 seconds)

```
set vpn l2tp remote-access authentication radius dynamic-author server <address>
```

Specifies IP address for Dynamic Authorization Extension server (DM/CoA)

```
set vpn l2tp remote-access authentication radius dynamic-author port <port>
```

Port for Dynamic Authorization Extension server (DM/CoA)

```
set vpn l2tp remote-access authentication radius dynamic-author key <secret>
```

Secret for Dynamic Authorization Extension server (DM/CoA)

```
set vpn l2tp remote-access authentication radius max-try <number>
```

Maximum number of tries to send Access-Request/Accounting-Request queries

```
set vpn l2tp remote-access authentication radius timeout <timeout>
```

Timeout to wait response from server (seconds)

```
set vpn l2tp remote-access authentication radius nas-identifier <identifier>
```

Value to send to RADIUS server in NAS-Identifier attribute and to be matched in DM/CoA requests.

```
set vpn l2tp remote-access authentication radius nas-ip-address <address>
```

Value to send to RADIUS server in NAS-IP-Address attribute and to be matched in DM/CoA requests. Also DM/CoA server will bind to that address.

```
set vpn l2tp remote-access authentication radius source-address <address>
```

Source IPv4 address used in all RADIUS server queries.

```
set vpn l2tp remote-access authentication radius rate-limit attribute <attribute>
```

Specifies which RADIUS server attribute contains the rate limit information. The default attribute is *Filter-Id*.

---

**Bemerkung:** If you set a custom RADIUS attribute you must define it on both dictionaries at RADIUS server and client.

---

**set vpn l2tp remote-access authentication radius rate-limit enable**

Enables bandwidth shaping via RADIUS.

**set vpn l2tp remote-access authentication radius rate-limit vendor**

Specifies the vendor dictionary, dictionary needs to be in /usr/share/accel-ppp/radius.

Received RADIUS attributes have a higher priority than parameters defined within the CLI configuration, refer to the explanation below.

### Allocation clients ip addresses by RADIUS

If the RADIUS server sends the attribute *Framed-IP-Address* then this IP address will be allocated to the client and the option *default-pool* within the CLI config is being ignored.

If the RADIUS server sends the attribute *Framed-Pool*, IP address will be allocated from a predefined IP pool whose name equals the attribute value.

If the RADIUS server sends the attribute *Stateful-IPv6-Address-Pool*, IPv6 address will be allocated from a predefined IPv6 pool *prefix* whose name equals the attribute value.

If the RADIUS server sends the attribute *Delegated-IPv6-Prefix-Pool*, IPv6 delegation prefix will be allocated from a predefined IPv6 pool *delegate* whose name equals the attribute value.

---

**Bemerkung:** *Stateful-IPv6-Address-Pool* and *Delegated-IPv6-Prefix-Pool* are defined in RFC6911. If they are not defined in your RADIUS server, add new [dictionary](#).

---

User interface can be put to VRF context via RADIUS Access-Accept packet, or change it via RADIUS CoA. *Accel-VRF-Name* is used from these purposes. It is custom [ACCEL-PPP attribute](#). Define it in your RADIUS server.

### Renaming clients interfaces by RADIUS

If the RADIUS server uses the attribute *NAS-Port-Id*, ppp tunnels will be renamed.

---

**Bemerkung:** The value of the attribute *NAS-Port-Id* must be less than 16 characters, otherwise the interface won't be renamed.

---

## Configuring LNS (L2TP Network Server)

LNS are often used to connect to a LAC (L2TP Access Concentrator).

```
set vpn l2tp remote-access lns host-name <hostname>
```

Sent to the client (LAC) in the Host-Name attribute

```
set vpn l2tp remote-access lns shared-secret <secret>
```

Tunnel password used to authenticate the client (LAC)

To explain the usage of LNS follow our blueprint [PPPoE over L2TP](#).

## IPv6

```
set vpn l2tp remote-access ppp-options ipv6 <require | prefer | allow | deny>
```

Specifies IPv6 negotiation preference.

- **require** - Require IPv6 negotiation
- **prefer** - Ask client for IPv6 negotiation, do not fail if it rejects
- **allow** - Negotiate IPv6 only if client requests
- **deny** - Do not negotiate IPv6 (default value)

```
set vpn l2tp remote-access client-ipv6-pool <IPv6-POOL-NAME> prefix <address> mask <number-of-bits>
```

Use this comand to set the IPv6 address pool from which an l2tp client will get an IPv6 prefix of your defined length (mask) to terminate the l2tp endpoint at their side. The mask length can be set from 48 to 128 bit long, the default value is 64.

```
set vpn l2tp remote-access client-ipv6-pool <IPv6-POOL-NAME> delegate <address> delegation-prefix <number-of-bits>
```

Use this command to configure DHCPv6 Prefix Delegation (RFC3633) on l2tp. You will have to set your IPv6 pool and the length of the delegation prefix. From the defined IPv6 pool you will be handing out networks of the defined length (delegation-prefix). The length of the delegation prefix can be set from 32 to 64 bit long.

```
set vpn l2tp remote-access default-ipv6-pool <IPv6-POOL-NAME>
```

Use this command to define default IPv6 address pool name.

```
set vpn l2tp remote-access ppp-options ipv6 allow
set vpn l2tp remote-access client-ipv6-pool IPv6-POOL delegate '2001:db8:8003::/48'
↪delegation-prefix '56'
set vpn l2tp remote-access client-ipv6-pool IPv6-POOL prefix '2001:db8:8002::/48' mask
↪'64'
set vpn l2tp remote-access default-ipv6-pool IPv6-POOL
```

## IPv6 Advanced Options

**set vpn l2tp remote-access ppp-options ipv6-accept-peer-interface-id**

Accept peer interface identifier. By default is not defined.

**set vpn l2tp remote-access ppp-options ipv6-interface-id <random | x:x:x:x>**

Specifies fixed or random interface identifier for IPv6. By default is fixed.

- **random** - Random interface identifier for IPv6
- **x:x:x:x** - Specify interface identifier for IPv6

**set vpn l2tp remote-access ppp-options ipv6-interface-id <random | x:x:x:x>**

Specifies peer interface identifier for IPv6. By default is fixed.

- **random** - Random interface identifier for IPv6
- **x:x:x:x** - Specify interface identifier for IPv6
- **ipv4-addr** - Calculate interface identifier from IPv4 address.
- **calling-sid** - Calculate interface identifier from calling-station-id.

## Scripting

**set vpn l2tp remote-access extended-scripts on-change <path\_to\_script>**

Script to run when session interface changed by RADIUS CoA handling

**set vpn l2tp remote-access extended-scripts on-down <path\_to\_script>**

Script to run when session interface going to terminate

**set vpn l2tp remote-access extended-scripts on-pre-up <path\_to\_script>**

Script to run before session interface comes up

**set vpn l2tp remote-access extended-scripts on-up <path\_to\_script>**

Script to run when session interface is completely configured and started

## Advanced Options

### Authentication Advanced Options

**set vpn l2tp remote-access authentication local-users username <user> disable**

Disable <user> account.

**set vpn l2tp remote-access authentication local-users username <user> static-ip <address>**

Assign static IP address to <user> account.

**set vpn l2tp remote-access authentication local-users username <user> rate-limit download <bandwidth>**

Download bandwidth limit in kbit/s for <user>.

**set vpn l2tp remote-access authentication local-users username <user> rate-limit upload <bandwidth>**

Upload bandwidth limit in kbit/s for *<user>*.

```
set vpn l2tp remote-access authentication protocols <pap | chap | mschap | mschap-v2>
```

Require the peer to authenticate itself using one of the following protocols: pap, chap, mschap, mschap-v2.

### Client IP Pool Advanced Options

```
set vpn l2tp remote-access client-ip-pool <POOL-NAME> next-pool <NEXT-POOL-NAME>
```

Use this command to define the next address pool name.

### PPP Advanced Options

```
set vpn l2tp remote-access ppp-options disable-ccp
```

Disable Compression Control Protocol (CCP). CCP is enabled by default.

```
set vpn l2tp remote-access ppp-options interface-cache <number>
```

Specifies number of interfaces to keep in cache. It means that don't destroy interface after corresponding session is destroyed, instead place it to cache and use it later for new sessions repeatedly. This should reduce kernel-level interface creation/deletion rate lack. Default value is **0**.

```
set vpn l2tp remote-access ppp-options ipv4 <require | prefer | allow | deny>
```

Specifies IPv4 negotiation preference.

- **require** - Require IPv4 negotiation
- **prefer** - Ask client for IPv4 negotiation, do not fail if it rejects
- **allow** - Negotiate IPv4 only if client requests (Default value)
- **deny** - Do not negotiate IPv4

```
set vpn l2tp remote-access ppp-options lcp-echo-failure <number>
```

Defines the maximum *<number>* of unanswered echo requests. Upon reaching the value *<number>*, the session will be reset. Default value is **3**.

```
set vpn l2tp remote-access ppp-options lcp-echo-interval <interval>
```

If this option is specified and is greater than 0, then the PPP module will send LCP pings of the echo request every *<interval>* seconds. Default value is **30**.

```
set vpn l2tp remote-access ppp-options lcp-echo-timeout
```

Specifies timeout in seconds to wait for any peer activity. If this option specified it turns on adaptive lcp echo functionality and „lcp-echo-failure“ is not used. Default value is **0**.

```
set vpn l2tp remote-access ppp-options min-mtu <number>
```

Defines minimum acceptable MTU. If client will try to negotiate less then specified MTU then it will be NAKed or disconnected if rejects greater MTU. Default value is **100**.

```
set vpn l2tp remote-access ppp-options mppe <require | prefer | deny>
```

Specifies MPPE negotiation preference.

- **require** - ask client for mppe, if it rejects drop connection
- **prefer** - ask client for mppe, if it rejects don't fail. (Default value)

- **deny** - deny mppe

Default behavior - don't ask client for mppe, but allow it if client wants. Please note that RADIUS may override this option by MS-MPPE-Encryption-Policy attribute.

**set vpn l2tp remote-access ppp-options mru <number>**

Defines preferred MRU. By default is not defined.

## Global Advanced options

**set vpn l2tp remote-access description <description>**

Set description.

**set vpn l2tp remote-access limits burst <value>**

Burst count

**set vpn l2tp remote-access limits connection-limit <value>**

Acceptable rate of connections (e.g. 1/min, 60/sec)

**set vpn l2tp remote-access limits timeout <value>**

Timeout in seconds

**set vpn l2tp remote-access mtu**

Maximum Transmission Unit (MTU) (default: **1436**)

**set vpn l2tp remote-access max-concurrent-sessions**

Maximum number of concurrent session start attempts

**set vpn l2tp remote-access name-server <address>**

Connected client should use <address> as their DNS server. This command accepts both IPv4 and IPv6 addresses. Up to two nameservers can be configured for IPv4, up to three for IPv6.

**set vpn l2tp remote-access shaper fwmark <1-2147483647>**

Match firewall mark value

**set vpn l2tp remote-access snmp master-agent**

Enable SNMP

**set vpn l2tp remote-access wins-server <address>**

Windows Internet Name Service (WINS) servers propagated to client

## Monitoring

```
vyos@vyos:~$ show l2tp-server sessions
ifname | username |      ip      | ip6 | ip6-dp | calling-sid | rate-limit | state | 
--uptime | rx-bytes | tx-bytes
-----+-----+-----+-----+-----+-----+-----+-----+
l2tp0 | test      | 192.168.255.3 |     |         | 192.168.0.36 |           | active | 
02:01:47 | 7.7 KiB  | 1.2 KiB
```

```
vyos@vyos:~$ show l2tp-server statistics
uptime: 0.02:49:49
cpu: 0%
mem(rss/virt): 5920/100892 kB

```

### 8.13.3 OpenConnect

OpenConnect-compatible server feature is available from this release. Openconnect VPN supports SSL connection and offers full network access. SSL VPN network extension connects the end-user system to the corporate network with access controls based only on network layer information, such as destination IP address and port number. So, it provides safe communication for all types of device traffic across public networks and private networks, also encrypts the traffic with SSL protocol.

The remote user will use the openconnect client to connect to the router and will receive an IP address from a VPN pool, allowing full access to the network.

## Configuration

### SSL Certificates

We need to generate the certificate which authenticates users who attempt to access the network resource through the SSL VPN tunnels. The following commands will create a self signed certificates and will be stored in configuration:

```
run generate pki ca install <CA name>
run generate pki certificate sign <CA name> install <Server name>
```

We can also create the certificates using Certbot which is an easy-to-use client that fetches a certificate from Let's Encrypt an open certificate authority launched by the EFF, Mozilla, and others and deploys it to a web server.

```
sudo certbot certonly --standalone --preferred-challenges http -d <domain name>
```

### Server Configuration

```
set vpn openconnect authentication local-users username <user> password <pass>
set vpn openconnect authentication mode <local password|radius>
set vpn openconnect network-settings client-ip-settings subnet <subnet>
set vpn openconnect network-settings name-server <address>
set vpn openconnect network-settings name-server <address>
set vpn openconnect ssl ca-certificate <pki-ca-name>
set vpn openconnect ssl certificate <pki-cert-name>
set vpn openconnect ssl passphrase <pki-password>
```

### 2FA OTP support

Instead of password only authentication, 2FA password authentication + OTP key can be used. Alternatively, OTP authentication only, without a password, can be used. To do this, an OTP configuration must be added to the configuration above:

```
set vpn openconnect authentication mode local <password-otp|otp>
set vpn openconnect authentication local-users username <user> otp <key>
set vpn openconnect authentication local-users username <user> interval <interval>
↳(optional)>
set vpn openconnect authentication local-users username <user> otp-length <otp-length>
↳(optional)>
set vpn openconnect authentication local-users username <user> token-type <token-type>
↳(optional)>
```

For generating an OTP key in VyOS, you can use the CLI command (operational mode):

```
generate openconnect username <user> otp-key hotp-time
```

## Verification

```
vyos@vyos:~$ sh openconnect-server sessions
```

interface	username	ip	remote IP	RX	TX	state	↳
↳uptime							
-----	-----	-----	-----	-----	-----	-----	-----
↳---							
sslvpn0	tst	172.20.20.198	192.168.6.1	0 bytes	152 bytes	connected	3s

**Bemerkung:** It is compatible with Cisco (R) AnyConnect (R) clients.

### Example

## SSL Certificates generation

Follow the instructions to generate CA cert (in configuration mode):

```
vyos@vyos# run generate pki ca install ca-ocserv
Enter private key type: [rsa, dsa, ec] (Default: rsa)
Enter private key bits: (Default: 2048)
Enter country code: (Default: GB) US
Enter state: (Default: Some-State) Delaware
Enter locality: (Default: Some-City) Mycity
Enter organization name: (Default: VyOS) MyORG
Enter common name: (Default: vyos.io) oc-ca
Enter how many days certificate will be valid: (Default: 1825) 3650
Note: If you plan to use the generated key on this router, do not encrypt the private_
key.
Do you want to encrypt the private key with a passphrase? [y/N] N
2 value(s) installed. Use "compare" to see the pending changes, and "commit" to apply.
[edit]
```

Follow the instructions to generate server cert (in configuration mode):

```
vyos@vyos# run generate pki certificate sign ca-ocserv install srv-ocserv
Do you already have a certificate request? [y/N] N
Enter private key type: [rsa, dsa, ec] (Default: rsa)
Enter private key bits: (Default: 2048)
Enter country code: (Default: GB) US
Enter state: (Default: Some-State) Delaware
Enter locality: (Default: Some-City) Mycity
Enter organization name: (Default: VyOS) MyORG
Enter common name: (Default: vyos.io) oc-srv
Do you want to configure Subject Alternative Names? [y/N] N
Enter how many days certificate will be valid: (Default: 365) 1830
Enter certificate type: (client, server) (Default: server)
Note: If you plan to use the generated key on this router, do not encrypt the private_
key.
Do you want to encrypt the private key with a passphrase? [y/N] N
2 value(s) installed. Use "compare" to see the pending changes, and "commit" to apply.
[edit]
```

Each of the install command should be applied to the configuration and committed before using under the openconnect configuration:

```
vyos@vyos# commit
[edit]
vyos@vyos# save
Saving configuration to '/config/config.boot'...
Done
[edit]
```

## Openconnect Configuration

Simple setup with one user added and password authentication:

```
set vpn openconnect authentication local-users username tst password 'OC_bad_Secret'
set vpn openconnect authentication mode local password
set vpn openconnect network-settings client-ip-settings subnet '172.20.20.0/24'
set vpn openconnect network-settings name-server '10.1.1.1'
set vpn openconnect network-settings name-server '10.1.1.2'
set vpn openconnect ssl ca-certificate 'ca-ocserv'
set vpn openconnect ssl certificate 'srv-ocserv'
```

To enable the HTTP security headers in the configuration file, use the command:

```
set vpn openconnect http-security-headers
```

## Adding a 2FA with an OTP-key

First the OTP keys must be generated and sent to the user and to the configuration:

```
vyos@vyos:~$ generate openconnect username tst otp-key hotp-time
# You can share it with the user, he just needs to scan the QR in his OTP app
# username:  tst
# OTP KEY:  5PA4SGYTQSGOB03H3EQSSNCUNZAYAPH2
# OTP URL:  otpauth://totp/tst@vyos?secret=5PA4SGYTQSGOB03H3EQSSNCUNZAYAPH2&digits=6&
↳ period=30
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
# To add this OTP key to configuration, run the following commands:
set vpn openconnect authentication local-users username tst otp key
↪ 'ebc1c91b13848ce0bb67d9212934546e41803cfa'
```

Next it is necessary to configure 2FA for OpenConnect:

```
set vpn openconnect authentication mode local password-otp
set vpn openconnect authentication local-users username tst otp key
↪ 'ebc1c91b13848ce0bb67d9212934546e41803cfa'
```

Now when connecting the user will first be asked for the password and then the OTP key.

**Warnung:** When using Time-based one-time password (TOTP) (OTP HOTP-time), be sure that the time on the server and the OTP token generator are synchronized by NTP

To display the configured OTP user settings, use the command:

```
show openconnect-server user <username> otp <full|key-b32|key-hex|qrcode|uri>
```

## Identity Based Configuration

OpenConnect supports a subset of its configuration options to be applied on a per user/group basis, for configuration purposes we refer to this functionality as „Identity based config“. The following [OpenConnect Server Manual](#) outlines the set of configuration options that are allowed. This can be leveraged to apply different sets of configs to different users or groups of users.

```
sudo mkdir -p /config/auth/ocserv/config-per-user
sudo touch /config/auth/ocserv/default-user.conf

set vpn set vpn openconnect authentication identity-based-config mode user
set vpn openconnect authentication identity-based-config directory /config/auth/ocserv/
↪ config-per-user
set vpn openconnect authentication identity-based-config default-config /config/auth/
↪ ocserv/default-user.conf
```

**Warnung:** The above directory and default-config must be a child directory of /config/auth, since files outside this directory are not persisted after an image upgrade.

Once you commit the above changes you can create a config file in the /config/auth/ocserv/config-per-user directory that matches a username of a user you have created e.g. „tst“. Now when logging in with the „tst“ user the config options you set in this file will be loaded.

Be sure to set a sane default config in the default config file, this will be loaded in the case that a user is authenticated and no file is found in the configured directory matching the users username/group.

```
sudo nano /config/auth/ocserv/config-per-user/tst
```

The same configuration options apply when Identity based config is configured in group mode except that group mode can only be used with RADIUS authentication.

**Warnung:** OpenConnect server matches the filename in a case sensitive manner, make sure the username/group name you configure matches the filename exactly.

## Configuring RADIUS accounting

OpenConnect can be configured to send accounting information to a RADIUS server to capture user session data such as time of connect/disconnect, data transferred, and so on.

Configure an accounting server and enable accounting with:

```
set vpn openconnect accounting mode radius
set vpn openconnect accounting radius server 172.20.20.10
set vpn openconnect accounting radius server 172.20.20.10 port 1813
set vpn openconnect accounting radius server 172.20.20.10 key your_radius_secret
```

**Warnung:** The RADIUS accounting feature must be used with the OpenConnect authentication mode RADIUS. It cannot be used with local authentication. You must configure the OpenConnect authentication mode to „radius“.

An example of the data captured by a FREERADIUS server with sql accounting:

```
mysql> SELECT username, nasipaddress, acctstarttime, acctstoptime, acctinputoctets,
↪acctoutputoctets, callingstationid, framedipaddress, connectinfo_start FROM radacct;
+-----+-----+-----+-----+-----+-----+-----+-----+
↪+-----+-----+-----+-----+-----+-----+-----+-----+
↪-----+
| username | nasipaddress | acctstarttime | acctstoptime | acctinputoctets |
↪| acctoutputoctets | callingstationid | framedipaddress | connectinfo_start |
↪| |
+-----+-----+-----+-----+-----+-----+-----+-----+
↪+-----+-----+-----+-----+-----+-----+-----+-----+
↪-----+
| test | 198.51.100.15 | 2023-01-13 00:59:15 | 2023-01-13 00:59:21 | 10606 |
↪| 152 | 192.168.6.1 | 172.20.20.198 | Open AnyConnect VPN Agent |
↪v8.05-1 |
+-----+-----+-----+-----+-----+-----+-----+-----+
↪+-----+-----+-----+-----+-----+-----+-----+-----+
↪-----+
```

### 8.13.4 PPTP-Server

The Point-to-Point Tunneling Protocol (*PPTP*) has been implemented in VyOS only for backwards compatibility. PPTP has many well known security issues and you should use one of the many other new VPN implementations.

#### Configuring PPTP Server

```
set vpn pptp remote-access authentication mode local
set vpn pptp remote-access authentication local-users username test password 'test'
set vpn pptp remote-access client-ip-pool PPTP-POOL range 192.168.255.2-192.168.255.254
set vpn pptp remote-access default-pool 'PPTP-POOL'
set vpn pptp remote-access outside-address 192.0.2.2
set vpn pptp remote-access gateway-address 192.168.255.1
```

**set vpn pptp remote-access authentication mode <local | radius>**

Set authentication backend. The configured authentication backend is used for all queries.

- **radius:** All authentication queries are handled by a configured RADIUS server.
- **local:** All authentication queries are handled locally.
- **noauth:** Authentication disabled.

**set vpn pptp remote-access authentication local-users username <user> password <pass>**

Create <user> for local authentication on this system. The users password will be set to <pass>.

**set vpn pptp remote-access client-ip-pool <POOL-NAME> range <x.x.x.x-x.x.x.x | x.x.x.x/x>**

Use this command to define the first IP address of a pool of addresses to be given to PPTP clients. If notation x.x.x.x-x.x.x.x, it must be within a /24 subnet. If notation x.x.x.x/x is used there is possibility to set host/netmask.

**set vpn pptp remote-access default-pool <POOL-NAME>**

Use this command to define default address pool name.

**set vpn pptp remote-access gateway-address <gateway>**

Specifies single <gateway> IP address to be used as local address of PPP interfaces.

#### Configuring RADIUS authentication

To enable RADIUS based authentication, the authentication mode needs to be changed within the configuration. Previous settings like the local users, still exists within the configuration, however they are not used if the mode has been changed from local to radius. Once changed back to local, it will use all local accounts again.

```
set vpn pptp remote-access authentication mode radius
```

**set vpn pptp remote-access authentication radius server <server> key <secret>**

Configure RADIUS <server> and its required shared <secret> for communicating with the RADIUS server.

Since the RADIUS server would be a single point of failure, multiple RADIUS servers can be setup and will be used subsequently. For example:

```
set vpn pptp remote-access authentication radius server 10.0.0.1 key 'foo'
set vpn pptp remote-access authentication radius server 10.0.0.2 key 'foo'
```

**Bemerkung:** Some RADIUS servers use an access control list which allows or denies queries, make sure to add your VyOS router to the allowed client list.

---

## RADIUS source address

If you are using OSPF as IGP, always the closest interface connected to the RADIUS server is used. You can bind all outgoing RADIUS requests to a single source IP e.g. the loopback interface.

```
set vpn pptp remote-access authentication radius source-address <address>
```

Source IPv4 address used in all RADIUS server queries.

**Bemerkung:** The source-address must be configured on one of VyOS interface. Best practice would be a loopback or dummy interface.

---

## RADIUS advanced options

```
set vpn pptp remote-access authentication radius server <server> port <port>
```

Configure RADIUS <server> and its required port for authentication requests.

```
set vpn pptp remote-access authentication radius server <server> fail-time <time>
```

Mark RADIUS server as offline for this given <time> in seconds.

```
set vpn pptp remote-access authentication radius server <server> disable
```

Temporary disable this RADIUS server.

```
set vpn pptp remote-access authentication radius acct-timeout <timeout>
```

Timeout to wait reply for Interim-Update packets. (default 3 seconds)

```
set vpn pptp remote-access authentication radius dynamic-author server <address>
```

Specifies IP address for Dynamic Authorization Extension server (DM/CoA)

```
set vpn pptp remote-access authentication radius dynamic-author port <port>
```

Port for Dynamic Authorization Extension server (DM/CoA)

```
set vpn pptp remote-access authentication radius dynamic-author key <secret>
```

Secret for Dynamic Authorization Extension server (DM/CoA)

```
set vpn pptp remote-access authentication radius max-try <number>
```

Maximum number of tries to send Access-Request/Accounting-Request queries

```
set vpn pptp remote-access authentication radius timeout <timeout>
```

Timeout to wait response from server (seconds)

```
set vpn pptp remote-access authentication radius nas-identifier <identifier>
```

Value to send to RADIUS server in NAS-Identifier attribute and to be matched in DM/CoA requests.

```
set vpn pptp remote-access authentication radius nas-ip-address <address>
```

Value to send to RADIUS server in NAS-IP-Address attribute and to be matched in DM/CoA requests. Also DM/CoA server will bind to that address.

**set vpn pptp remote-access authentication radius source-address <address>**

Source IPv4 address used in all RADIUS server queries.

**set vpn pptp remote-access authentication radius rate-limit attribute <attribute>**

Specifies which RADIUS server attribute contains the rate limit information. The default attribute is *Filter-Id*.

---

**Bemerkung:** If you set a custom RADIUS attribute you must define it on both dictionaries at RADIUS server and client.

---

**set vpn pptp remote-access authentication radius rate-limit enable**

Enables bandwidth shaping via RADIUS.

**set vpn pptp remote-access authentication radius rate-limit vendor**

Specifies the vendor dictionary, dictionary needs to be in /usr/share/accel-ppp/radius.

Received RADIUS attributes have a higher priority than parameters defined within the CLI configuration, refer to the explanation below.

### Allocation clients ip addresses by RADIUS

If the RADIUS server sends the attribute Framed-IP-Address then this IP address will be allocated to the client and the option default-pool within the CLI config is being ignored.

If the RADIUS server sends the attribute Framed-Pool, IP address will be allocated from a predefined IP pool whose name equals the attribute value.

If the RADIUS server sends the attribute Stateful-IPv6-Address-Pool, IPv6 address will be allocated from a predefined IPv6 pool prefix whose name equals the attribute value.

If the RADIUS server sends the attribute Delegated-IPv6-Prefix-Pool, IPv6 delegation prefix will be allocated from a predefined IPv6 pool delegate whose name equals the attribute value.

---

**Bemerkung:** Stateful-IPv6-Address-Pool and Delegated-IPv6-Prefix-Pool are defined in RFC6911. If they are not defined in your RADIUS server, add new [dictionary](#).

---

User interface can be put to VRF context via RADIUS Access-Accept packet, or change it via RADIUS CoA. Accel-VRF-Name is used from these purposes. It is custom [ACCEL-PPP attribute](#). Define it in your RADIUS server.

### Renaming clients interfaces by RADIUS

If the RADIUS server uses the attribute NAS-Port-Id, ppp tunnels will be renamed.

---

**Bemerkung:** The value of the attribute NAS-Port-Id must be less than 16 characters, otherwise the interface won't be renamed.

---

## IPv6

**set vpn pptp remote-access ppp-options ipv6 <require | prefer | allow | deny>**

Specifies IPv6 negotiation preference.

- **require** - Require IPv6 negotiation
- **prefer** - Ask client for IPv6 negotiation, do not fail if it rejects
- **allow** - Negotiate IPv6 only if client requests
- **deny** - Do not negotiate IPv6 (default value)

**set vpn pptp remote-access client-ipv6-pool <IPv6-POOL-NAME> prefix <address> mask <number-of-bits>**

Use this command to set the IPv6 address pool from which an PPTP client will get an IPv6 prefix of your defined length (mask) to terminate the PPTP endpoint at their side. The mask length can be set from 48 to 128 bit long, the default value is 64.

**set vpn pptp remote-access client-ipv6-pool <IPv6-POOL-NAME> delegate <address> delegation-prefix <number-of-bits>**

Use this command to configure DHCPv6 Prefix Delegation (RFC3633) on PPTP. You will have to set your IPv6 pool and the length of the delegation prefix. From the defined IPv6 pool you will be handing out networks of the defined length (delegation-prefix). The length of the delegation prefix can be set from 32 to 64 bit long.

**set vpn pptp remote-access default-ipv6-pool <IPv6-POOL-NAME>**

Use this command to define default IPv6 address pool name.

```
set vpn pptp remote-access ppp-options ipv6 allow
set vpn pptp remote-access client-ipv6-pool IPv6-POOL delegate '2001:db8:8003::/48'
↪ delegation-prefix '56'
set vpn pptp remote-access client-ipv6-pool IPv6-POOL prefix '2001:db8:8002::/48' mask
↪ '64'
set vpn pptp remote-access default-ipv6-pool IPv6-POOL
```

## IPv6 Advanced Options

**set vpn pptp remote-access ppp-options ipv6-accept-peer-interface-id**

Accept peer interface identifier. By default is not defined.

**set vpn pptp remote-access ppp-options ipv6-interface-id <random | x:x:x:x>**

Specifies fixed or random interface identifier for IPv6. By default is fixed.

- **random** - Random interface identifier for IPv6
- **x:x:x:x** - Specify interface identifier for IPv6

**set vpn pptp remote-access ppp-options ipv6-interface-id <random | x:x:x:x>**

Specifies peer interface identifier for IPv6. By default is fixed.

- **random** - Random interface identifier for IPv6
- **x:x:x:x** - Specify interface identifier for IPv6
- **ipv4-addr** - Calculate interface identifier from IPv4 address.
- **calling-sid** - Calculate interface identifier from calling-station-id.

## Scripting

**set vpn pptp remote-access extended-scripts on-change <path\_to\_script>**

Script to run when session interface changed by RADIUS CoA handling

**set vpn pptp remote-access extended-scripts on-down <path\_to\_script>**

Script to run when session interface going to terminate

**set vpn pptp remote-access extended-scripts on-pre-up <path\_to\_script>**

Script to run before session interface comes up

**set vpn pptp remote-access extended-scripts on-up <path\_to\_script>**

Script to run when session interface is completely configured and started

## Advanced Options

### Authentication Advanced Options

**set vpn pptp remote-access authentication local-users username <user> disable**

Disable <user> account.

**set vpn pptp remote-access authentication local-users username <user> static-ip <address>**

Assign static IP address to <user> account.

**set vpn pptp remote-access authentication local-users username <user> rate-limit download <bandwidth>**

Download bandwidth limit in kbit/s for <user>.

**set vpn pptp remote-access authentication local-users username <user> rate-limit upload <bandwidth>**

Upload bandwidth limit in kbit/s for <user>.

**set vpn pptp remote-access authentication protocols <pap | chap | mschap | mschap-v2>**

Require the peer to authenticate itself using one of the following protocols: pap, chap, mschap, mschap-v2.

### Client IP Pool Advanced Options

**set vpn pptp remote-access client-ip-pool <POOL-NAME> next-pool <NEXT-POOL-NAME>**

Use this command to define the next address pool name.

## PPP Advanced Options

**set vpn pptp remote-access ppp-options disable-ccp**

Disable Compression Control Protocol (CCP). CCP is enabled by default.

**set vpn pptp remote-access ppp-options interface-cache <number>**

Specifies number of interfaces to keep in cache. It means that don't destroy interface after corresponding session is destroyed, instead place it to cache and use it later for new sessions repeatedly. This should reduce kernel-level interface creation/deletion rate lack. Default value is **0**.

**set vpn pptp remote-access ppp-options ipv4 <require | prefer | allow | deny>**

Specifies IPv4 negotiation preference.

- **require** - Require IPv4 negotiation
- **prefer** - Ask client for IPv4 negotiation, do not fail if it rejects
- **allow** - Negotiate IPv4 only if client requests (Default value)
- **deny** - Do not negotiate IPv4

**set vpn pptp remote-access ppp-options lcp-echo-failure <number>**

Defines the maximum <number> of unanswered echo requests. Upon reaching the value <number>, the session will be reset. Default value is **3**.

**set vpn pptp remote-access ppp-options lcp-echo-interval <interval>**

If this option is specified and is greater than 0, then the PPP module will send LCP pings of the echo request every <interval> seconds. Default value is **30**.

**set vpn pptp remote-access ppp-options lcp-echo-timeout**

Specifies timeout in seconds to wait for any peer activity. If this option specified it turns on adaptive lcp echo functionality and „lcp-echo-failure“ is not used. Default value is **0**.

**set vpn pptp remote-access ppp-options min-mtu <number>**

Defines minimum acceptable MTU. If client will try to negotiate less then specified MTU then it will be NAKed or disconnected if rejects greater MTU. Default value is **100**.

**set vpn pptp remote-access ppp-options mppe <require | prefer | deny>**

Specifies MPPE negotiation preference.

- **require** - ask client for mppe, if it rejects drop connection
- **prefer** - ask client for mppe, if it rejects don't fail. (Default value)
- **deny** - deny mppe

Default behavior - don't ask client for mppe, but allow it if client wants. Please note that RADIUS may override this option by MS-MPPE-Encryption-Policy attribute.

**set vpn pptp remote-access ppp-options mru <number>**

Defines preferred MRU. By default is not defined.

## Global Advanced options

**set vpn pptp remote-access description <description>**

Set description.

**set vpn pptp remote-access limits burst <value>**

Burst count

**set vpn pptp remote-access limits connection-limit <value>**

Acceptable rate of connections (e.g. 1/min, 60/sec)

**set vpn pptp remote-access limits timeout <value>**

Timeout in seconds

**set vpn pptp remote-access mtu**

Maximum Transmission Unit (MTU) (default: **1436**)

**set vpn pptp remote-access max-concurrent-sessions**

Maximum number of concurrent session start attempts

**set vpn pptp remote-access name-server <address>**

Connected client should use <address> as their DNS server. This command accepts both IPv4 and IPv6 addresses. Up to two nameservers can be configured for IPv4, up to three for IPv6.

**set vpn pptp remote-access shaper fwmark <1-2147483647>**

Match firewall mark value

**set vpn pptp remote-access snmp master-agent**

Enable SNMP

**set vpn pptp remote-access wins-server <address>**

Windows Internet Name Service (WINS) servers propagated to client

## Monitoring

**show pptp-server sessions**

Use this command to locally check the active sessions in the PPTP server.

```
vyos@vyos:~$ show pptp-server sessions
ifname | username | ip | ip6 | ip6-dp | calling-sid | rate-limit | state |
↳ uptime | rx-bytes | tx-bytes
-----+-----+-----+-----+-----+-----+-----+-----+
↳ -----+-----+-----+
pptp0 | test | 10.0.0.2 | | | 192.168.10.100 | | active |
↳ 00:01:26 | 6.9 KiB | 220 B
```

```
vyos@vyos:~$ show pptp-server statistics
uptime: 0.00:04:52
cpu: 0%

### 8.13.5 RSA-Keys

RSA can be used for services such as key exchanges and for encryption purposes. To make IPSec work with dynamic address on one/both sides, we will have to use RSA keys for authentication. They are very fast and easy to setup.

First, on both routers run the operational command „generate pki key-pair install <key-pair nam>>“. You may choose different length than 2048 of course.

```
vyos@left# run generate pki key-pair install ipsec-LEFT
Enter private key type: [rsa, dsa, ec] (Default: rsa)
Enter private key bits: (Default: 2048)
Note: If you plan to use the generated key on this router, do not encrypt the private_
↪key.
Do you want to encrypt the private key with a passphrase? [y/N] N
Configure mode commands to install key pair:
Do you want to install the public key? [Y/n] Y
set pki key-pair ipsec-LEFT public key 'MIIBIjANBgkqh...'
Do you want to install the private key? [Y/n] Y
set pki key-pair ipsec-LEFT private key 'MIIEvgIBADAN...'
[edit]
```

Configuration commands will display. Note the command with the public key (set pki key-pair ipsec-LEFT public key ,MIIBIjANBgkqh...'). Then do the same on the opposite router:

```
vyos@left# run generate pki key-pair install ipsec-RIGHT
```

Note the command with the public key (set pki key-pair ipsec-RIGHT public key ,FAAOCAQ8AMII...').

The noted public keys should be entered on the opposite routers.

On the LEFT:

```
set pki key-pair ipsec-RIGHT public key 'FAAOCAQ8AMII...'
```

On the RIGHT:

```
set pki key-pair ipsec-LEFT public key 'MIIBIjANBgkqh...'
```

Now you are ready to setup IPsec. The key points:

1. Since both routers do not know their effective public addresses, we set the local-address of the peer to „any“.
2. On the initiator, we set the peer address to its public address, but on the responder we only set the id.
3. On the initiator, we need to set the remote-id option so that it can identify IKE traffic from the responder correctly.
4. On the responder, we need to set the local id so that initiator can know who's talking to it for the point #3 to work.

On the LEFT (static address):

```

set vpn ipsec interface eth0

set vpn ipsec esp-group MyESPGroup proposal 1 encryption aes128
set vpn ipsec esp-group MyESPGroup proposal 1 hash sha1

set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group 2
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption aes128
set vpn ipsec ike-group MyIKEGroup proposal 1 hash sha1

set vpn ipsec site-to-site peer @RIGHT authentication id LEFT
set vpn ipsec site-to-site peer @RIGHT authentication mode rsa
set vpn ipsec site-to-site peer @RIGHT authentication rsa local-key ipsec-LEFT
set vpn ipsec site-to-site peer @RIGHT authentication rsa remote-key ipsec-RIGHT
set vpn ipsec site-to-site peer @RIGHT authentication remote-id RIGHT
set vpn ipsec site-to-site peer @RIGHT default-esp-group MyESPGroup
set vpn ipsec site-to-site peer @RIGHT ike-group MyIKEGroup
set vpn ipsec site-to-site peer @RIGHT local-address 192.0.2.10
set vpn ipsec site-to-site peer @RIGHT connection-type respond
set vpn ipsec site-to-site peer @RIGHT tunnel 1 local prefix 192.168.99.1/32 #_
↪Additional loopback address on the local
set vpn ipsec site-to-site peer @RIGHT tunnel 1 remote prefix 192.168.99.2/32 #_
↪Additional loopback address on the remote

```

On the RIGHT (dynamic address):

```

set vpn ipsec interface eth0

set vpn ipsec esp-group MyESPGroup proposal 1 encryption aes128
set vpn ipsec esp-group MyESPGroup proposal 1 hash sha1

set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group 2
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption aes128
set vpn ipsec ike-group MyIKEGroup proposal 1 hash sha1

set vpn ipsec site-to-site peer 192.0.2.10 authentication id RIGHT
set vpn ipsec site-to-site peer 192.0.2.10 authentication mode rsa
set vpn ipsec site-to-site peer 192.0.2.10 authentication rsa local-key ipsec-RIGHT
set vpn ipsec site-to-site peer 192.0.2.10 authentication rsa remote-key ipsec-LEFT
set vpn ipsec site-to-site peer 192.0.2.10 authentication remote-id LEFT
set vpn ipsec site-to-site peer 192.0.2.10 connection-type initiate
set vpn ipsec site-to-site peer 192.0.2.10 default-esp-group MyESPGroup
set vpn ipsec site-to-site peer 192.0.2.10 ike-group MyIKEGroup
set vpn ipsec site-to-site peer 192.0.2.10 local-address any
set vpn ipsec site-to-site peer 192.0.2.10 tunnel 1 local prefix 192.168.99.2/32 #_
↪Additional loopback address on the local
set vpn ipsec site-to-site peer 192.0.2.10 tunnel 1 remote prefix 192.168.99.1/32 #_
↪Additional loopback address on the remote

```

### 8.13.6 SSTP Server

SSTP is a form of VPN (Virtual Private Network) tunnel that provides a mechanism to transport PPP traffic through an SSL/TLS channel. SSL/TLS provides transport-level security with key negotiation, encryption and traffic integrity checking. The use of SSL/TLS over TCP port 443 allows SSTP to pass through virtually all firewalls and proxy servers except for authenticated web proxies.

SSTP is available for Linux, BSD, and Windows.

VyOS utilizes `accel-ppp` to provide SSTP server functionality. We support both local and RADIUS authentication.

As SSTP provides PPP via a SSL/TLS channel the use of either publically signed certificates as well as a private PKI is required.

#### Configuring SSTP Server

##### Certificates

Using our documentation chapter - *PKI* generate and install CA and Server certificate

```
vyos@vyos:~$ generate pki ca install CA
```

```
vyos@vyos:~$ generate pki certificate sign CA install Server
```

##### Configuration

```
set vpn sstp authentication local-users username test password 'test'
set vpn sstp authentication mode 'local'
set vpn sstp client-ip-pool SSTP-POOL range '10.0.0.2-10.0.0.100'
set vpn sstp default-pool 'SSTP-POOL'
set vpn sstp gateway-address '10.0.0.1'
set vpn sstp ssl ca-certificate 'CA1'
set vpn sstp ssl certificate 'Server'
```

**set vpn sstp authentication mode <local | radius>**

Set authentication backend. The configured authentication backend is used for all queries.

- **radius:** All authentication queries are handled by a configured RADIUS server.
- **local:** All authentication queries are handled locally.

**set vpn sstp authentication local-users username <user> password <pass>**

Create <user> for local authentication on this system. The users password will be set to <pass>.

**set vpn sstp client-ip-pool <POOL-NAME> range <x.x.x.x-x.x.x.x | x.x.x.x/x>**

Use this command to define the first IP address of a pool of addresses to be given to SSTP clients. If notation `x.x.x.x-x.x.x.x`, it must be within a /24 subnet. If notation `x.x.x.x/x` is used there is possibility to set host/netmask.

**set vpn sstp default-pool <POOL-NAME>**

Use this command to define default address pool name.

**set vpn sstp gateway-address <gateway>**

Specifies single *<gateway>* IP address to be used as local address of PPP interfaces.

**set vpn sstp ssl ca-certificate <file>**

Name of installed certificate authority certificate.

**set vpn sstp ssl certificate <file>**

Name of installed server certificate.

## Configuring RADIUS authentication

To enable RADIUS based authentication, the authentication mode needs to be changed within the configuration. Previous settings like the local users, still exists within the configuration, however they are not used if the mode has been changed from local to radius. Once changed back to local, it will use all local accounts again.

```
set vpn sstp authentication mode radius
```

**set vpn sstp authentication radius server <server> key <secret>**

Configure RADIUS *<server>* and its required shared *<secret>* for communicating with the RADIUS server.

Since the RADIUS server would be a single point of failure, multiple RADIUS servers can be setup and will be used subsequently. For example:

```
set vpn sstp authentication radius server 10.0.0.1 key 'foo'
set vpn sstp authentication radius server 10.0.0.2 key 'foo'
```

---

**Bemerkung:** Some RADIUS servers use an access control list which allows or denies queries, make sure to add your VyOS router to the allowed client list.

---

## RADIUS source address

If you are using OSPF as IGP, always the closest interface connected to the RADIUS server is used. You can bind all outgoing RADIUS requests to a single source IP e.g. the loopback interface.

**set vpn sstp authentication radius source-address <address>**

Source IPv4 address used in all RADIUS server queries.

---

**Bemerkung:** The source-address must be configured on one of VyOS interface. Best practice would be a loopback or dummy interface.

---

## RADIUS advanced options

**set vpn sstp authentication radius server <server> port <port>**

Configure RADIUS <server> and its required port for authentication requests.

**set vpn sstp authentication radius server <server> fail-time <time>**

Mark RADIUS server as offline for this given <time> in seconds.

**set vpn sstp authentication radius server <server> disable**

Temporary disable this RADIUS server.

**set vpn sstp authentication radius acct-timeout <timeout>**

Timeout to wait reply for Interim-Update packets. (default 3 seconds)

**set vpn sstp authentication radius dynamic-author server <address>**

Specifies IP address for Dynamic Authorization Extension server (DM/CoA)

**set vpn sstp authentication radius dynamic-author port <port>**

Port for Dynamic Authorization Extension server (DM/CoA)

**set vpn sstp authentication radius dynamic-author key <secret>**

Secret for Dynamic Authorization Extension server (DM/CoA)

**set vpn sstp authentication radius max-try <number>**

Maximum number of tries to send Access-Request/Accounting-Request queries

**set vpn sstp authentication radius timeout <timeout>**

Timeout to wait response from server (seconds)

**set vpn sstp authentication radius nas-identifier <identifier>**

Value to send to RADIUS server in NAS-Identifier attribute and to be matched in DM/CoA requests.

**set vpn sstp authentication radius nas-ip-address <address>**

Value to send to RADIUS server in NAS-IP-Address attribute and to be matched in DM/CoA requests. Also DM/CoA server will bind to that address.

**set vpn sstp authentication radius source-address <address>**

Source IPv4 address used in all RADIUS server queries.

**set vpn sstp authentication radius rate-limit attribute <attribute>**

Specifies which RADIUS server attribute contains the rate limit information. The default attribute is *Filter-Id*.

---

**Bemerkung:** If you set a custom RADIUS attribute you must define it on both dictionaries at RADIUS server and client.

---

**set vpn sstp authentication radius rate-limit enable**

Enables bandwidth shaping via RADIUS.

**set vpn sstp authentication radius rate-limit vendor**

Specifies the vendor dictionary, dictionary needs to be in /usr/share/accel-ppp/radius.

Received RADIUS attributes have a higher priority than parameters defined within the CLI configuration, refer to the explanation below.

### Allocation clients ip addresses by RADIUS

If the RADIUS server sends the attribute `Framed-IP-Address` then this IP address will be allocated to the client and the option `default-pool` within the CLI config is being ignored.

If the RADIUS server sends the attribute `Framed-Pool`, IP address will be allocated from a predefined IP pool whose name equals the attribute value.

If the RADIUS server sends the attribute `Stateful-IPv6-Address-Pool`, IPv6 address will be allocated from a predefined IPv6 pool `prefix` whose name equals the attribute value.

If the RADIUS server sends the attribute `Delegated-IPv6-Prefix-Pool`, IPv6 delegation prefix will be allocated from a predefined IPv6 pool `delegate` whose name equals the attribute value.

---

**Bemerkung:** `Stateful-IPv6-Address-Pool` and `Delegated-IPv6-Prefix-Pool` are defined in RFC6911. If they are not defined in your RADIUS server, add new [dictionary](#).

---

User interface can be put to VRF context via RADIUS Access-Accept packet, or change it via RADIUS CoA. `Accel-VRF-Name` is used from these purposes. It is custom [ACCEL-PPP attribute](#). Define it in your RADIUS server.

### Renaming clients interfaces by RADIUS

If the RADIUS server uses the attribute `NAS-Port-Id`, ppp tunnels will be renamed.

---

**Bemerkung:** The value of the attribute `NAS-Port-Id` must be less than 16 characters, otherwise the interface won't be renamed.

---

## IPv6

**set vpn sstp ppp-options ipv6 <require | prefer | allow | deny>**

Specifies IPv6 negotiation preference.

- **require** - Require IPv6 negotiation
- **prefer** - Ask client for IPv6 negotiation, do not fail if it rejects
- **allow** - Negotiate IPv6 only if client requests
- **deny** - Do not negotiate IPv6 (default value)

**set vpn sstp client-ipv6-pool <IPv6-POOL-NAME> prefix <address> mask <number-of-bits>**

Use this command to set the IPv6 address pool from which an SSTP client will get an IPv6 prefix of your defined length (mask) to terminate the SSTP endpoint at their side. The mask length can be set from 48 to 128 bit long, the default value is 64.

**set vpn sstp client-ipv6-pool <IPv6-POOL-NAME> delegate <address> delegation-prefix <number-of-bits>**

Use this command to configure DHCPv6 Prefix Delegation (RFC3633) on SSTP. You will have to set your IPv6 pool and the length of the delegation prefix. From the defined IPv6 pool you will be handing out networks of the defined length (delegation-prefix). The length of the delegation prefix can be set from 32 to 64 bit long.

**set vpn sstp default-ipv6-pool <IPv6-POOL-NAME>**

Use this command to define default IPv6 address pool name.

```
set vpn sstp ppp-options ipv6 allow
set vpn sstp client-ipv6-pool IPv6-POOL delegate '2001:db8:8003::/48' delegation-prefix
↪ '56'
set vpn sstp client-ipv6-pool IPv6-POOL prefix '2001:db8:8002::/48' mask '64'
set vpn sstp default-ipv6-pool IPv6-POOL
```

## IPv6 Advanced Options

**set vpn sstp ppp-options ipv6-accept-peer-interface-id**

Accept peer interface identifier. By default is not defined.

**set vpn sstp ppp-options ipv6-interface-id <random | x:x:x:x>**

Specifies fixed or random interface identifier for IPv6. By default is fixed.

- **random** - Random interface identifier for IPv6
- **x:x:x:x** - Specify interface identifier for IPv6

**set vpn sstp ppp-options ipv6-interface-id <random | x:x:x:x>**

Specifies peer interface identifier for IPv6. By default is fixed.

- **random** - Random interface identifier for IPv6
- **x:x:x:x** - Specify interface identifier for IPv6
- **ipv4-addr** - Calculate interface identifier from IPv4 address.
- **calling-sid** - Calculate interface identifier from calling-station-id.

## Scripting

**set vpn sstp extended-scripts on-change <path\_to\_script>**

Script to run when session interface changed by RADIUS CoA handling

**set vpn sstp extended-scripts on-down <path\_to\_script>**

Script to run when session interface going to terminate

**set vpn sstp extended-scripts on-pre-up <path\_to\_script>**

Script to run before session interface comes up

**set vpn sstp extended-scripts on-up <path\_to\_script>**

Script to run when session interface is completely configured and started

## Advanced Options

### Authentication Advanced Options

**set vpn sstp authentication local-users username <user> disable**

Disable <user> account.

**set vpn sstp authentication local-users username <user> static-ip <address>**

Assign static IP address to <user> account.

**set vpn sstp authentication local-users username <user> rate-limit download <bandwidth>**

Download bandwidth limit in kbit/s for <user>.

**set vpn sstp authentication local-users username <user> rate-limit upload <bandwidth>**

Upload bandwidth limit in kbit/s for <user>.

**set vpn sstp authentication protocols <pap | chap | mschap | mschap-v2>**

Require the peer to authenticate itself using one of the following protocols: pap, chap, mschap, mschap-v2.

### Client IP Pool Advanced Options

**set vpn sstp client-ip-pool <POOL-NAME> next-pool <NEXT-POOL-NAME>**

Use this command to define the next address pool name.

### PPP Advanced Options

**set vpn sstp ppp-options disable-ccp**

Disable Compression Control Protocol (CCP). CCP is enabled by default.

**set vpn sstp ppp-options interface-cache <number>**

Specifies number of interfaces to keep in cache. It means that don't destroy interface after corresponding session is destroyed, instead place it to cache and use it later for new sessions repeatedly. This should reduce kernel-level interface creation/deletion rate lack. Default value is 0.

**set vpn sstp ppp-options ipv4 <require | prefer | allow | deny>**

Specifies IPv4 negotiation preference.

- **require** - Require IPv4 negotiation
- **prefer** - Ask client for IPv4 negotiation, do not fail if it rejects
- **allow** - Negotiate IPv4 only if client requests (Default value)
- **deny** - Do not negotiate IPv4

**set vpn sstp ppp-options lcp-echo-failure <number>**

Defines the maximum <number> of unanswered echo requests. Upon reaching the value <number>, the session will be reset. Default value is 3.

**set vpn sstp ppp-options lcp-echo-interval <interval>**

If this option is specified and is greater than 0, then the PPP module will send LCP pings of the echo request every <interval> seconds. Default value is 30.

**set vpn sstp ppp-options lcp-echo-timeout**

Specifies timeout in seconds to wait for any peer activity. If this option specified it turns on adaptive lcp echo functionality and „lcp-echo-failure“ is not used. Default value is **0**.

**set vpn sstp ppp-options min-mtu <number>**

Defines minimum acceptable MTU. If client will try to negotiate less then specified MTU then it will be NAKed or disconnected if rejects greater MTU. Default value is **100**.

**set vpn sstp ppp-options mppe <require | prefer | deny>**

Specifies MPPE negotiation preference.

- **require** - ask client for mppe, if it rejects drop connection
- **prefer** - ask client for mppe, if it rejects don't fail. (Default value)
- **deny** - deny mppe

Default behavior - don't ask client for mppe, but allow it if client wants. Please note that RADIUS may override this option by MS-MPPE-Encryption-Policy attribute.

**set vpn sstp ppp-options mru <number>**

Defines preferred MRU. By default is not defined.

**Global Advanced options****set vpn sstp description <description>**

Set description.

**set vpn sstp limits burst <value>**

Burst count

**set vpn sstp limits connection-limit <value>**

Acceptable rate of connections (e.g. 1/min, 60/sec)

**set vpn sstp limits timeout <value>**

Timeout in seconds

**set vpn sstp mtu**

Maximum Transmission Unit (MTU) (default: **1500**)

**set vpn sstp max-concurrent-sessions**

Maximum number of concurrent session start attempts

**set vpn sstp name-server <address>**

Connected client should use <address> as their DNS server. This command accepts both IPv4 and IPv6 addresses. Up to two nameservers can be configured for IPv4, up to three for IPv6.

**set vpn sstp shaper fwmark <1-2147483647>**

Match firewall mark value

**set vpn sstp snmp master-agent**

Enable SNMP

**set vpn sstp wins-server <address>**

Windows Internet Name Service (WINS) servers propagated to client

**set vpn sstp host-name <hostname>**

If this option is given, only SSTP connections to the specified host and with the same TLS SNI will be allowed.

## Configuring SSTP client

Once you have setup your SSTP server there comes the time to do some basic testing. The Linux client used for testing is called `sstpc`. `sstpc` requires a PPP configuration/peer file.

If you use a self-signed certificate, do not forget to install CA on the client side.

The following PPP configuration tests MSCHAP-v2:

```
$ cat /etc/ppp/peers/vyos
usepeerdns
#require-mppe
#require-pap
require-mschap-v2
noauth
lock
refuse-pap
refuse-eap
refuse-chap
refuse-mschap
#refuse-mschap-v2
nobsdcomp
nodeflate
debug
```

You can now „dial“ the peer with the following command: `sstpc --log-level 4 --log-stderr --user vyos --password vyos vpn.example.com -- call vyos`.

A connection attempt will be shown as:

```
$ sstpc --log-level 4 --log-stderr --user vyos --password vyos vpn.example.com -- call_
↪vyos

### 8.13.7 DMVPN

DMVPN (Dynamic Multipoint Virtual Private Network) is a dynamic VPN technology originally developed by Cisco. While their implementation was somewhat proprietary, the underlying technologies are actually standards based. The three technologies are:

- NHRP (Next Hop Resolution Protocol) [RFC 2332](#)
- mGRE (Multipoint Generic Routing Encapsulation) [RFC 1702](#)
- IPSec (IP Security) - too many RFCs to list, but start with [RFC 4301](#)

NHRP provides the dynamic tunnel endpoint discovery mechanism (endpoint registration, and endpoint discovery/lookup), mGRE provides the tunnel encapsulation itself, and the IPSec protocols handle the key exchange, and crypto mechanism.

In short, DMVPN provides the capability for creating a dynamic-mesh VPN network without having to pre-configure (static) all possible tunnel end-point peers.

---

**Bemerkung:** DMVPN only automates the tunnel endpoint discovery and setup. A complete solution also incorporates the use of a routing protocol. BGP is particularly well suited for use with DMVPN.

---

Abb. 6: Baseline DMVPN topology

## Configuration

- Please refer to the [Tunnel](#) documentation for the individual tunnel related options.
- Please refer to the [IPsec](#) documentation for the individual IPsec related options.

**set protocols nhrp tunnel <tunnel> cisco-authentication <secret>**

Enables Cisco style authentication on NHRP packets. This embeds the secret plaintext password to the outgoing NHRP packets. Incoming NHRP packets on this interface are discarded unless the secret password is present. Maximum length of the secret is 8 characters.

**set protocols nhrp tunnel <tunnel> dynamic-map <address> nbma-domain-name <fqdn>**

Specifies that the NBMA (Non-broadcast multiple-access network) addresses of the next hop servers are defined in the domain name nbma-domain-name. For each A record opennhrp creates a dynamic NHS entry.

Each dynamic NHS will get a peer entry with the configured network address and the discovered NBMA address.

The first registration request is sent to the protocol broadcast address, and the server's real protocol address is dynamically detected from the first registration reply.

**set protocols nhrp tunnel <tunnel> holding-time <timeout>**

Specifies the holding time for NHRP Registration Requests and Resolution Replies sent from this interface or shortcut-target. The holdtime is specified in seconds and defaults to two hours.

**set protocols nhrp tunnel <tunnel> map cisco**

If the statically mapped peer is running Cisco IOS, specify the cisco keyword. It is used to fix statically the Registration Request ID so that a matching Purge Request can be sent if NBMA address has changed. This is to work around broken IOS which requires Purge Request ID to match the original Registration Request ID.

**set protocols nhrp tunnel <tunnel> map nbma-address <address>**

Creates static peer mapping of protocol-address to NBMA address.

If the IP prefix mask is present, it directs opennhrp to use this peer as a next hop server when sending Resolution Requests matching this subnet.

This is also known as the HUBs IP address or FQDN.

**set protocols nhrp tunnel <tunnel> map register**

The optional parameter register specifies that Registration Request should be sent to this peer on startup.

This option is required when running a DMVPN spoke.

**set protocols nhrp tunnel <tunnel> multicast <dynamic | nhs>**

Determines how opennhrp daemon should soft switch the multicast traffic. Currently, multicast traffic is captured by opennhrp daemon using a packet socket, and resent back to proper destinations. This means that multicast packet sending is CPU intensive.

Specifying nhs makes all multicast packets to be repeated to each statically configured next hop.

Dynamic instructs to forward to all peers which we have a direct connection with. Alternatively, you can specify the directive multiple times for each protocol-address the multicast traffic should be sent to.

**Warnung:** It is very easy to misconfigure multicast repeating if you have multiple NHSes.

#### **set protocols nhrp tunnel <tunnel> non-caching**

Disables caching of peer information from forwarded NHRP Resolution Reply packets. This can be used to reduce memory consumption on big NBMA subnets.

---

**Bemerkung:** Currently does not do much as caching is not implemented.

---

#### **set protocols nhrp tunnel <tunnel> redirect**

Enable sending of Cisco style NHRP Traffic Indication packets. If this is enabled and opennhrp detects a forwarded packet, it will send a message to the original sender of the packet instructing it to create a direct connection with the destination. This is basically a protocol independent equivalent of ICMP redirect.

#### **set protocols nhrp tunnel <tunnel> shortcut**

Enable creation of shortcut routes.

A received NHRP Traffic Indication will trigger the resolution and establishment of a shortcut route.

#### **set protocols nhrp tunnel <tunnel> shortcut-destination**

This instructs opennhrp to reply with authoritative answers on NHRP Resolution Requests destined to addresses in this interface (instead of forwarding the packets). This effectively allows the creation of shortcut routes to subnets located on the interface.

When specified, this should be the only keyword for the interface.

#### **set protocols nhrp tunnel <tunnel> shortcut-target <address>**

Defines an off-NBMA network prefix for which the GRE interface will act as a gateway. This an alternative to defining local interfaces with shortcut-destination flag.

#### **set protocols nhrp tunnel <tunnel> shortcut-target <address> holding-time <timeout>**

Specifies the holding time for NHRP Registration Requests and Resolution Replies sent from this interface or shortcut-target. The holdtime is specified in seconds and defaults to two hours.

### **Example**

This blueprint uses VyOS as the DMVPN Hub and Cisco (7206VXR) and VyOS as multiple spoke sites. The lab was build using EVE-NG (Emulated Virtual Environment NG).

Each node (Hub and Spoke) uses an IP address from the network 172.16.253.128/29.

The below referenced IP address *192.0.2.1* is used as example address representing a global unicast address under which the HUB can be contacted by each and every individual spoke.

Abb. 7: DMVPN example network

## Configuration

### Hub

```
set interfaces ethernet eth0 address 192.0.2.1/24

set interfaces tunnel tun100 address '172.16.253.134/29'
set interfaces tunnel tun100 encapsulation 'gre'
set interfaces tunnel tun100 source-address '192.0.2.1'
set interfaces tunnel tun100 enable-multicast
set interfaces tunnel tun100 parameters ip key '1'

set protocols nhrp tunnel tun100 cisco-authentication 'secret'
set protocols nhrp tunnel tun100 holding-time '300'
set protocols nhrp tunnel tun100 multicast 'dynamic'
set protocols nhrp tunnel tun100 redirect
set protocols nhrp tunnel tun100 shortcut

set vpn ipsec esp-group ESP-HUB lifetime '1800'
set vpn ipsec esp-group ESP-HUB mode 'transport'
set vpn ipsec esp-group ESP-HUB pfs 'dh-group2'
set vpn ipsec esp-group ESP-HUB proposal 1 encryption 'aes256'
set vpn ipsec esp-group ESP-HUB proposal 1 hash 'sha1'
set vpn ipsec esp-group ESP-HUB proposal 2 encryption '3des'
set vpn ipsec esp-group ESP-HUB proposal 2 hash 'md5'
set vpn ipsec ike-group IKE-HUB key-exchange 'ikev1'
set vpn ipsec ike-group IKE-HUB lifetime '3600'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set vpn ipsec ike-group IKE-HUB proposal 1 dh-group '2'
set vpn ipsec ike-group IKE-HUB proposal 1 encryption 'aes256'
set vpn ipsec ike-group IKE-HUB proposal 1 hash 'sha1'
set vpn ipsec ike-group IKE-HUB proposal 2 dh-group '2'
set vpn ipsec ike-group IKE-HUB proposal 2 encryption 'aes128'
set vpn ipsec ike-group IKE-HUB proposal 2 hash 'sha1'

set vpn ipsec interface 'eth0'

set vpn ipsec profile NHRPVPN authentication mode 'pre-shared-secret'
set vpn ipsec profile NHRPVPN authentication pre-shared-secret 'secret'
set vpn ipsec profile NHRPVPN bind tunnel 'tun100'
set vpn ipsec profile NHRPVPN esp-group 'ESP-HUB'
set vpn ipsec profile NHRPVPN ike-group 'IKE-HUB'

```

**Bemerkung:** Setting this up on AWS will require a „Custom Protocol Rule“ for protocol number „47“ (GRE) Allow Rule in TWO places. Firstly on the VPC Network ACL, and secondly on the security group network ACL attached to the EC2 instance. This has been tested as working for the official AMI image on the AWS Marketplace. (Locate the correct VPC and security group by navigating through the details pane below your EC2 instance in the AWS console).

## Spoke

The individual spoke configurations only differ in the local IP address on the tun10 interface. See the above diagram for the individual IP addresses.

### spoke01-spoke04

```

### 8.13.8 Site-to-Site

Site-to-site mode provides a way to add remote peers, which could be configured to exchange encrypted information between them and VyOS itself or connected/routed networks.

To configure site-to-site connection you need to add peers with the `set vpn ipsec site-to-site peer <name>` command.

The peer name must be an alphanumeric and can have hyphen or underscore as special characters. It is purely informational.

Each site-to-site peer has the next options:

- **authentication** - configure authentication between VyOS and a remote peer. If pre-shared-secret mode is used, the secret key must be defined in `set vpn ipsec authentication` and suboptions:
  - **psk** - Preshared secret key name;
  - **dhcp-interface** - ID for authentication generated from DHCP address dynamically;
  - **id** - static ID's for authentication. In general local and remote address `<x.x.x.x>`, `<h:h:h:h:h:h:h:h>` or `%any`;
  - **secret** - predefined shared secret. Used if configured mode `pre-shared-secret`;
  - **local-id** - ID for the local VyOS router. If defined, during the authentication it will be send to remote peer;
  - **mode** - mode for authentication between VyOS and remote peer:
  - **pre-shared-secret** - use predefined shared secret phrase;
  - **rsa** - use simple shared RSA key.
  - **x509** - use certificates infrastructure for authentication.
  - **remote-id** - define an ID for remote peer, instead of using peer name or address. Useful in case if the remote peer is behind NAT or if mode `x509` is used;
  - **rsa** - options for RSA authentication mode:
  - **local-key** - name of PKI key-pair with local private key
  - **remote-key** - name of PKI key-pair with remote public key
  - **passphrase** - local private key passphrase

- `use-x509-id` - use local ID from x509 certificate. Cannot be used when `id` is defined;
- `x509` - options for x509 authentication mode:
- `ca-certificate` - CA certificate in PKI configuration. Using for authenticating remote peer;
- `certificate` - certificate file in PKI configuration, which will be used for authenticating local router on remote peer;
- `passphrase` - private key passphrase, if needed.
- `connection-type` - how to handle this connection process. Possible variants:
  - `initiate` - does initial connection to remote peer immediately after configuring and after boot. In this mode the connection will not be restarted in case of disconnection, therefore should be used only together with DPD or another session tracking methods;
  - `respond` - does not try to initiate a connection to a remote peer. In this mode, the IPSec session will be established only after initiation from a remote peer. Could be useful when there is no direct connectivity to the peer due to firewall or NAT in the middle of the local and remote side.
  - `none` - loads the connection only, which then can be manually initiated or used as a responder configuration.
- `default-esp-group` - ESP group to use by default for traffic encryption. Might be overwritten by individual settings for tunnel or VTI interface binding;
- `description` - description for this peer;
- `dhcp-interface` - use an IP address, received from DHCP for IPSec connection with this peer, instead of `local-address`;
- `force-udp-encapsulation` - force encapsulation of ESP into UDP datagrams. Useful in case if between local and remote side is firewall or NAT, which not allows passing plain ESP packets between them;
- `ike-group` - IKE group to use for key exchanges;
- `ikev2-reauth` - reauthenticate remote peer during the rekeying process. Can be used only with IKEv2. Create a new `IKE_SA` from the scratch and try to recreate all IPSec SAs;
- `local-address` - local IP address for IPSec connection with this peer. If defined any, then an IP address which configured on interface with default route will be used;
- `remote-address` - remote IP address or hostname for IPSec connection. IPv4 or IPv6 address is used when a peer has a public static IP address. Hostname is a DNS name which could be used when a peer has a public IP address and DNS name, but an IP address could be changed from time to time.
- `replay-window` - IPsec replay window to configure for this `CHILD_SA` (default: 32), a value of 0 disables IPsec replay protection
- `tunnel` - define criteria for traffic to be matched for encrypting and send it to a peer:
  - `disable` - disable this tunnel;
  - `esp-group` - define ESP group for encrypt traffic, defined by this tunnel;
  - `local` - define a local source for match traffic, which should be encrypted and send to this peer;
  - `port` - define port. Have effect only when used together with `prefix`;
  - `prefix` - IP network at local side.
  - `priority` - Add priority for policy-based IPSec VPN tunnels(lowest value more preferable)
  - `protocol` - define the protocol for match traffic, which should be encrypted and send to this peer;
  - `remote` - define the remote destination for match traffic, which should be encrypted and send to this peer;

- **port** - define port. Have effect only when used together with **prefix**;
- **prefix** - IP network at remote side.
- **vti** - use a VTI interface for traffic encryption. Any traffic, which will be send to VTI interface will be encrypted and send to this peer. Using VTI makes IPSec configuration much flexible and easier in complex situation, and allows to dynamically add/delete remote networks, reachable via a peer, as in this mode router don't need to create additional SA/policy for each remote network;
- **bind** - select a VTI interface to bind to this peer;
- **esp-group** - define ESP group for encrypt traffic, passed this VTI interface.
- **virtual-address** - Defines a virtual IP address which is requested by the initiator and one or several IPv4 and/or IPv6 addresses are assigned from multiple pools by the responder.

## Examples:

### IKEv1

#### Example:

- WAN interface on *eth1*
- left subnet: *192.168.0.0/24* site1, server side (i.e. locality, actually there is no client or server roles)
- left local\_ip: *198.51.100.3* # server side WAN IP
- right subnet: *10.0.0.0/24* site2,remote office side
- right local\_ip: *203.0.113.2* # remote office side WAN IP

```
# server config
set vpn ipsec authentication psk OFFICE-B id '198.51.100.3'
set vpn ipsec authentication psk OFFICE-B id '203.0.113.2'
set vpn ipsec authentication psk OFFICE-B secret 'SomePreSharedKey'
set vpn ipsec esp-group office-srv-esp lifetime '1800'
set vpn ipsec esp-group office-srv-esp mode 'tunnel'
set vpn ipsec esp-group office-srv-esp pfs 'enable'
set vpn ipsec esp-group office-srv-esp proposal 1 encryption 'aes256'
set vpn ipsec esp-group office-srv-esp proposal 1 hash 'sha1'
set vpn ipsec ike-group office-srv-ike key-exchange 'ikev1'
set vpn ipsec ike-group office-srv-ike lifetime '3600'
set vpn ipsec ike-group office-srv-ike proposal 1 encryption 'aes256'
set vpn ipsec ike-group office-srv-ike proposal 1 hash 'sha1'
set vpn ipsec interface 'eth1'
set vpn ipsec site-to-site peer OFFICE-B authentication local-id '198.51.100.3'
set vpn ipsec site-to-site peer OFFICE-B authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer OFFICE-B authentication remote-id '203.0.113.2'
set vpn ipsec site-to-site peer OFFICE-B ike-group 'office-srv-ike'
set vpn ipsec site-to-site peer OFFICE-B local-address '198.51.100.3'
set vpn ipsec site-to-site peer OFFICE-B remote-address '203.0.113.2'
set vpn ipsec site-to-site peer OFFICE-B tunnel 0 esp-group 'office-srv-esp'
set vpn ipsec site-to-site peer OFFICE-B tunnel 0 local prefix '192.168.0.0/24'
set vpn ipsec site-to-site peer OFFICE-B tunnel 0 remote prefix '10.0.0.0/21'

# remote office config

If there is SNAT rules on eth1, need to add exclude rule

```

# server side
set nat source rule 10 destination address '10.0.0.0/24'
set nat source rule 10 'exclude'
set nat source rule 10 outbound-interface name 'eth1'
set nat source rule 10 source address '192.168.0.0/24'

# remote office side
set nat source rule 10 destination address '192.168.0.0/24'
set nat source rule 10 'exclude'

```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
set nat source rule 10 outbound-interface name 'eth1'
set nat source rule 10 source address '10.0.0.0/24'
```

To allow traffic to pass through to clients, you need to add the following rules. (if you used the default configuration at the top of this page)

```
# server side
set firewall name OUTSIDE-LOCAL rule 32 action 'accept'
set firewall name OUTSIDE-LOCAL rule 32 source address '10.0.0.0/24'

# remote office side
set firewall name OUTSIDE-LOCAL rule 32 action 'accept'
set firewall name OUTSIDE-LOCAL rule 32 source address '192.168.0.0/24'
```

## IKEv2

Example:

- left local\_ip: 192.168.0.10 # VPN Gateway, behind NAT device
- left public\_ip: 172.18.201.10
- right local\_ip: 172.18.202.10 # right side WAN IP

Imagine the following topology

Abb. 8: IPsec IKEv2 site2site VPN (source ./draw.io/vpn\_s2s\_ikev2.drawio)

**LEFT:** \* WAN interface on *eth0.201* \* *eth0.201* interface IP: *172.18.201.10/24* \* *vti10* interface IP: *10.0.0.2/31* \* *dum0* interface IP: *10.0.11.1/24* (for testing purposes)

**RIGHT:** \* WAN interface on *eth0.202* \* *eth0.201* interface IP: *172.18.202.10/24* \* *vti10* interface IP: *10.0.0.3/31* \* *dum0* interface IP: *10.0.12.1/24* (for testing purposes)

**Bemerkung:** Don't get confused about the used /31 tunnel subnet. [RFC 3021](#) gives you additional information for using /31 subnets on point-to-point links.

```

#### Key Parameters:

- **authentication local-id/remote-id** - IKE identification is used for validation of VPN peer devices during IKE negotiation. If you do not configure local/remote-identity, the device uses the IPv4 or IPv6 address that corresponds to the local/remote peer by default. In certain network setups (like ipsec interface with dynamic address, or behind the NAT), the IKE ID received from the peer does not match the IKE gateway configured on the device. This can lead to a Phase 1 validation failure. So, make sure to configure the local/remote id explicitly and ensure that the IKE ID is the same as the remote-identity configured on the peer device.
- **disable-route-autoinstall** - This option when configured disables the routes installed in the default table 220 for site-to-site ipsec. It is mostly used with VTI configuration.
- **dead-peer-detection action = clear | trap | restart** - R\_U\_THERE notification messages(IKEv1) or empty INFORMATIONAL messages (IKEv2) are periodically sent in order to check the liveness of the IPsec peer. The values clear, trap, and restart all activate DPD and determine the action to perform on a timeout. With clear the connection is closed with no further actions taken. trap installs a trap

policy, which will catch matching traffic and tries to re-negotiate the connection on demand. `restart` will immediately trigger an attempt to re-negotiate the connection.

- `close-action = none | clear | trap | start` - defines the action to take if the remote peer unexpectedly closes a CHILD\_SA (see above for meaning of values). A closeaction should not be used if the peer uses reauthentication or uniqueids.

When the `close-action` option is set on the peers, the connection-type of each peer has to be considered carefully. For example, if the option is set on both peers, then both would attempt to initiate and hold open multiple copies of each child SA. This might lead to instability of the device or cpu/memory utilization.

Below flow-chart could be a quick reference for the close-action combination depending on how the peer is configured.

Abb. 9: Similar combinations are applicable for the dead-peer-detection.

### 8.13.9 IPsec IKEv2 Remote Access VPN

Internet Key Exchange version 2 (IKEv2) is a tunneling protocol, based on IPsec, that establishes a secure VPN communication between VPN devices, and defines negotiation and authentication processes for IPsec security associations (SAs). It is often known as IKEv2/IPsec or IPsec IKEv2 remote-access — or road-warriors as others call it.

Key exchange and payload encryption is done using IKE and ESP proposals as known from IKEv1 but the connections are faster to establish, more reliable, and also support roaming from IP to IP (called MOBIKE which makes sure your connection does not drop when changing networks from e.g. WIFI to LTE and back). Authentication can be achieved with X.509 certificates.

## Setting up certificates:

First of all, we need to create a CA root certificate and server certificate on the server side.

```

vyos@vpn.vyos.net# run generate pki ca install ca_root
Enter private key type: [rsa, dsa, ec] (Default: rsa)
Enter private key bits: (Default: 2048)
Enter country code: (Default: GB)
Enter state: (Default: Some-State)
Enter locality: (Default: Some-City)
Enter organization name: (Default: VyOS)
Enter common name: (Default: vyos.io)
Enter how many days certificate will be valid: (Default: 1825)
Note: If you plan to use the generated key on this router, do not encrypt the private_
↵key.
Do you want to encrypt the private key with a passphrase? [y/N] N
2 value(s) installed. Use "compare" to see the pending changes, and "commit" to apply.
[edit]

vyos@vpn.vyos.net# comp
[pki ca]
+ ca_root {
+   certificate "MIIDnTCCAoWgAwI...."
+   private {
+       key "MIIEvAIBADANBgkqhkiG9...."

vyos@vpn.vyos.net# run generate pki certificate sign ca_root install server_cert
Do you already have a certificate request? [y/N] N
Enter private key type: [rsa, dsa, ec] (Default: rsa)
Enter private key bits: (Default: 2048)
Enter country code: (Default: GB)
Enter state: (Default: Some-State)
Enter locality: (Default: Some-City)
Enter organization name: (Default: VyOS)
Enter common name: (Default: vyos.io) vpn.vyos.net
Do you want to configure Subject Alternative Names? [y/N] N
Enter how many days certificate will be valid: (Default: 365)
Enter certificate type: (client, server) (Default: server)
Note: If you plan to use the generated key on this router, do not encrypt the private_
↵key.
Do you want to encrypt the private key with a passphrase? [y/N] N
2 value(s) installed. Use "compare" to see the pending changes, and "commit" to apply.

vyos@vpn.vyos.net# comp
[pki certificate]
+ server_cert {
+   certificate "MIIDuzCCAqOgAwIBAgIUaSrCPWx....."
+   private {
+       key "MIIEvQIBADANBgkqhkiG9w0BAQEFAASCBA....."
+   }
+ }

```

Once the command is completed, it will add the certificate to the configuration session, to the pki subtree. You can then

review the proposed changes and commit them.

### Setting up IPsec:

After the PKI certs are all set up we can start configuring our IPsec/IKE proposals used for key-exchange and data encryption. The used encryption ciphers and integrity algorithms vary from operating system to operating system. The ones used in this example are validated to work on Windows 10.

```
set vpn ipsec esp-group ESP-RW lifetime '3600'
set vpn ipsec esp-group ESP-RW pfs 'disable'
set vpn ipsec esp-group ESP-RW proposal 10 encryption 'aes128gcm128'
set vpn ipsec esp-group ESP-RW proposal 10 hash 'sha256'

set vpn ipsec ike-group IKE-RW key-exchange 'ikev2'
set vpn ipsec ike-group IKE-RW lifetime '7200'
set vpn ipsec ike-group IKE-RW proposal 10 dh-group '14'
set vpn ipsec ike-group IKE-RW proposal 10 encryption 'aes128gcm128'
set vpn ipsec ike-group IKE-RW proposal 10 hash 'sha256'
```

Every connection/remote-access pool we configure also needs a pool where we can draw our client IP addresses from. We provide one IPv4 and IPv6 pool. Authorized clients will receive an IPv4 address from the configured IPv4 prefix and an IPv6 address from the IPv6 prefix. We can also send some DNS nameservers down to our clients used on their connection.

```
set vpn ipsec remote-access pool ra-rw-ipv4 name-server '192.0.2.1'
set vpn ipsec remote-access pool ra-rw-ipv4 prefix '192.0.2.128/25'

set vpn ipsec remote-access pool ra-rw-ipv6 name-server '2001:db8:1000::1'
set vpn ipsec remote-access pool ra-rw-ipv6 prefix '2001:db8:2000::/64'
```

### Setting up tunnel:

```
set vpn ipsec remote-access connection rw authentication local-id '192.0.2.1'
set vpn ipsec remote-access connection rw authentication server-mode 'x509'
set vpn ipsec remote-access connection rw authentication x509 ca-certificate 'ca_root'
set vpn ipsec remote-access connection rw authentication x509 certificate 'server_cert'
set vpn ipsec remote-access connection rw esp-group 'ESP-RW'
set vpn ipsec remote-access connection rw ike-group 'IKE-RW'
set vpn ipsec remote-access connection rw local-address '192.0.2.1'
set vpn ipsec remote-access connection rw pool 'ra-rw-ipv4'
set vpn ipsec remote-access connection rw pool 'ra-rw-ipv6'
```

VyOS also supports two different modes of authentication, local and RADIUS. To create a new local user named „vyos“ with a password of „vyos“ use the following commands.

```
set vpn ipsec remote-access connection rw authentication client-mode 'eap-mschapv2'
set vpn ipsec remote-access connection rw authentication local-users username vyos
↪password 'vyos'
```

## Client Configuration

Most operating systems include native client support for IPsec IKEv2 VPN connections, and others typically have an app or add-on package which adds the capability. This section covers IPsec IKEv2 client configuration for Windows 10.

VyOS provides a command to generate a connection profile used by Windows clients that will connect to the „rw“ connection on our VyOS server.

**Bemerkung:** Windows expects the server name to be also used in the server’s certificate common name, so it’s best to use this DNS name for your VPN connection.

```
vyos@vpn.vyos.net:~$ generate ipsec profile windows-remote-access rw remote vpn.vyos.net

==== <snip> ====
Add-VpnConnection -Name "VyOS IKEv2 VPN" -ServerAddress "vpn.vyos.net" -TunnelType "Ikev2
↪ "

Set-VpnConnectionIPsecConfiguration -ConnectionName "VyOS IKEv2 VPN" -
↪ AuthenticationTransformConstants GCMAES128 -CipherTransformConstants
GCMAES128 -EncryptionMethod GCMAES128 -IntegrityCheckMethod SHA256128 -PfsGroup None -
↪ DHGroup "Group14" -PassThru -Force
==== </snip> ====
```

Add the commands from Snippet in the Windows side via PowerShell. Also import the root CA cert to the Windows “Trusted Root Certification Authorities” and establish the connection.

### Verification:

```
vyos@vpn.vyos.net:~$ show vpn ipsec remote-access summary
  Connection ID Username Protocol State Uptime Tunnel IP Remote Host
↪ Remote ID IKE Proposal IPsec Proposal
-----
↪ -----
↪ -----
5 vyos IKEv2 UP 37s 192.0.2.129 10.0.0.2
↪ 10.0.0.2 AES_GCM_16-128/PRF_HMAC_SHA2_256/MODP_2048 ESP:AES_GCM_16-128
```

## 8.14 VRF

VRF devices combined with ip rules provides the ability to create virtual routing and forwarding domains (aka VRFs, VRF-lite to be specific) in the Linux network stack. One use case is the multi-tenancy problem where each tenant has their own unique routing tables and in the very least need different default gateways.

### 8.14.1 Configuration

A VRF device is created with an associated route table. Network interfaces are then enslaved to a VRF device.

**set vrf name <name>**

Create new VRF instance with <name>. The name is used when placing individual interfaces into the VRF.

**set vrf name <name> table <id>**

Configured routing table <id> is used by VRF <name>.

---

**Bemerkung:** A routing table ID can not be modified once it is assigned. It can only be changed by deleting and re-adding the VRF instance.

---

**set vrf bind-to-all**

By default the scope of the port bindings for unbound sockets is limited to the default VRF. That is, it will not be matched by packets arriving on interfaces enslaved to a VRF and processes may bind to the same port if they bind to a VRF.

TCP & UDP services running in the default VRF context (ie., not bound to any VRF device) can work across all VRF domains by enabling this option.

#### Zebra/Kernel route filtering

Zebra supports prefix-lists and Route Maps to match routes received from other FRR components. The permit/deny facilities provided by these commands can be used to filter which routes zebra will install in the kernel.

**set vrf <name> ip protocol <protocol> route-map <route-map>**

Apply a route-map filter to routes for the specified protocol.

The following protocols can be used: any, babel, bgp, connected, eigrp, isis, kernel, ospf, rip, static, table

---

**Bemerkung:** If you choose any as the option that will cause all protocols that are sending routes to zebra.

---

**set vrf <name> ipv6 protocol <protocol> route-map <route-map>**

Apply a route-map filter to routes for the specified protocol.

The following protocols can be used: any, babel, bgp, connected, isis, kernel, ospfv3, ripng, static, table

---

**Bemerkung:** If you choose any as the option that will cause all protocols that are sending routes to zebra.

---

## Nexthop Tracking

Nexthop tracking resolve nexthops via the default route by default. This is enabled by default for a traditional profile of FRR which we use. It and can be disabled if you do not want to e.g. allow BGP to peer across the default route.

**set vrf name <name> ip nht no-resolve-via-default**

Do not allow IPv4 nexthop tracking to resolve via the default route. This parameter is configured per-VRF, so the command is also available in the VRF subnode.

**set vrf name <name> ipv6 nht no-resolve-via-default**

Do not allow IPv6 nexthop tracking to resolve via the default route. This parameter is configured per-VRF, so the command is also available in the VRF subnode.

## Interfaces

When VRFs are used it is not only mandatory to create a VRF but also the VRF itself needs to be assigned to an interface.

**set interfaces <dummy | ethernet | bonding | bridge | pppoe> <interface> vrf <name>**

Assign interface identified by <interface> to VRF named <name>.

## Routing

---

**Bemerkung:** VyOS 1.4 (sagitta) introduced dynamic routing support for VRFs.

---

Currently dynamic routing is supported for the following protocols:

- *BGP*
- *IS-IS*
- *OSPF*
- *OSPFv3 (IPv6)*
- *Static*

The CLI configuration is same as mentioned in above articles. The only difference is, that each routing protocol used, must be prefixed with the *vrf name <name>* command.

## Example

The following commands would be required to set options for a given dynamic routing protocol inside a given vrf:

- *BGP*: **set vrf name <name> protocols bgp ...**
- *IS-IS*: **set vrf name <name> protocols isis ...**
- *OSPF*: **set vrf name <name> protocols ospf ...**
- *OSPFv3 (IPv6)*: **set vrf name <name> protocols ospfv3 ...**
- *Static*: **set vrf name <name> protocols static ...**

## 8.14.2 Operation

It is not sufficient to only configure a VRF but VRFs must be maintained, too. For VRF maintenance the following operational commands are in place.

### show vrf

Lists VRFs that have been created

```
vyos@vyos:~$ show vrf
VRF name      state      mac address      flags      interfaces
-----
blue          up        00:53:12:d8:74:24 noarp, master, up, lower_up dum200,
→eth0.302
red          up        00:53:de:02:df:aa noarp, master, up, lower_up dum100,
→eth0.300, bond0.100, peth0
```

**Bemerkung:** Command should probably be extended to list also the real interfaces assigned to this one VRF to get a better overview.

### show vrf <name>

```
vyos@vyos:~$ show vrf name blue
VRF name      state      mac address      flags      interfaces
-----
blue          up        00:53:12:d8:74:24 noarp, master, up, lower_up dum200,
→eth0.302
```

### show ip route vrf <name>

Display IPv4 routing table for VRF identified by <name>.

```
vyos@vyos:~$ show ip route vrf blue
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

VRF blue:
K  0.0.0.0/0 [255/8192] unreachable (ICMP unreachable), 00:00:50
S>* 172.16.0.0/16 [1/0] via 192.0.2.1, dum1, 00:00:02
C>* 192.0.2.0/24 is directly connected, dum1, 00:00:06
```

### show ipv6 route vrf <name>

Display IPv6 routing table for VRF identified by <name>.

```
vyos@vyos:~$ show ipv6 route vrf red
Codes: K - kernel route, C - connected, S - static, R - RIPng,
       O - OSPFv3, I - IS-IS, B - BGP, N - NHRP, T - Table,
       v - VNC, V - VNC-Direct, A - Babel, D - SHARP, F - PBR,
       f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
VRF red:
K   ::/0 [255/8192] unreachable (ICMP unreachable), 00:43:20
C>* 2001:db8::/64 is directly connected, dum1, 00:02:19
C>* fe80::/64 is directly connected, dum1, 00:43:19
K>* ff00::/8 [0/256] is directly connected, dum1, 00:43:19
```

**ping <host> vrf <name>**

The ping command is used to test whether a network host is reachable or not.

Ping uses ICMP protocol's mandatory ECHO\_REQUEST datagram to elicit an ICMP ECHO\_RESPONSE from a host or gateway. ECHO\_REQUEST datagrams (pings) will have an IP and ICMP header, followed by „struct timeval“ and an arbitrary number of pad bytes used to fill out the packet.

When doing fault isolation with ping, you should first run it on the local host, to verify that the local network interface is up and running. Then, continue with hosts and gateways further down the road towards your destination. Round-trip time and packet loss statistics are computed.

Duplicate packets are not included in the packet loss calculation, although the round-trip time of these packets is used in calculating the minimum/ average/maximum round-trip time numbers.

---

**Bemerkung:** Ping command can be interrupted at any given time using <Ctrl>+c. A brief statistic is shown afterwards.

---

```
vyos@vyos:~$ ping 192.0.2.1 vrf red
PING 192.0.2.1 (192.0.2.1) 56(84) bytes of data.
64 bytes from 192.0.2.1: icmp_seq=1 ttl=64 time=0.070 ms
64 bytes from 192.0.2.1: icmp_seq=2 ttl=64 time=0.078 ms
^C
--- 192.0.2.1 ping statistics ---
2 packets transmitted, 2 received, 0% packet loss, time 4ms
rtt min/avg/max/mdev = 0.070/0.074/0.078/0.004 ms
```

**traceroute vrf <name> [ipv4 | ipv6] <host>**

Displays the route packets taken to a network host utilizing VRF instance identified by <name>. When using the IPv4 or IPv6 option, displays the route packets taken to the given hosts IP address family. This option is useful when the host is specified as a hostname rather than an IP address.

**force vrf <name>**

Join a given VRF. This will open a new subshell within the specified VRF.

The prompt is adjusted to reflect this change in both config and op-mode.

```
vyos@vyos:~$ force vrf blue
vyos@vyos(vrf:blue):~$
```

### 8.14.3 Example

#### VRF route leaking

The following example topology was built using EVE-NG.

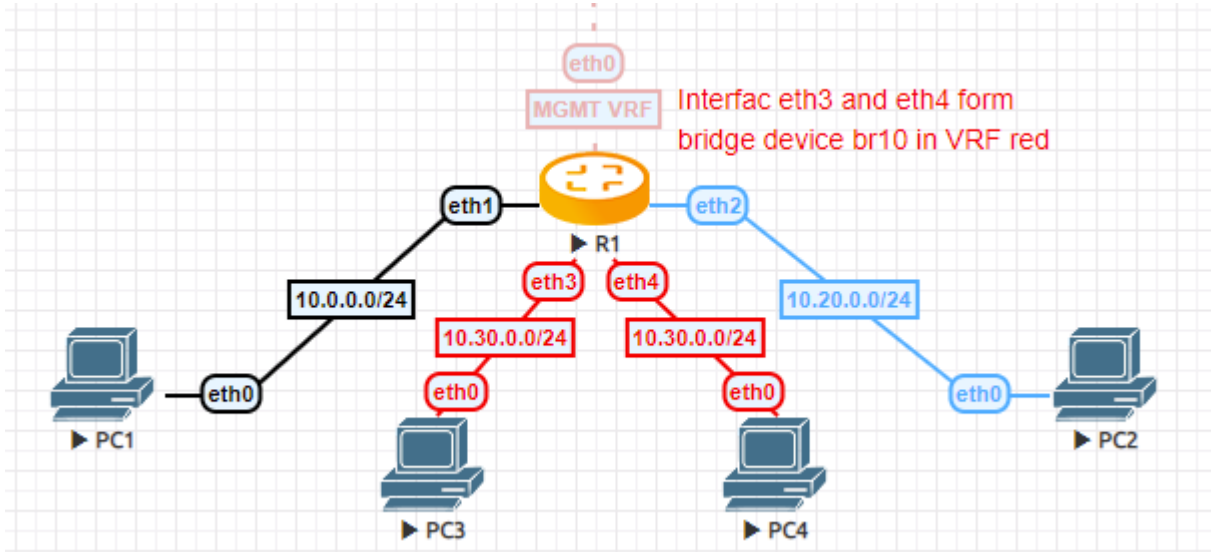

Abb. 10: VRF route leaking

- PC1 is in the default VRF and acting as e.g. a „fileserver“
- PC2 is in VRF blue which is the development department
- PC3 and PC4 are connected to a bridge device on router R1 which is in VRF red. Say this is the HR department.
- R1 is managed through an out-of-band network that resides in VRF mgmt

#### Configuration

```
set interfaces bridge br10 address '10.30.0.254/24'
set interfaces bridge br10 member interface eth3
set interfaces bridge br10 member interface eth4
set interfaces bridge br10 vrf 'red'

set interfaces ethernet eth0 address 'dhcp'
set interfaces ethernet eth0 vrf 'mgmt'
set interfaces ethernet eth1 address '10.0.0.254/24'
set interfaces ethernet eth2 address '10.20.0.254/24'
set interfaces ethernet eth2 vrf 'blue'

set protocols static route 10.20.0.0/24 interface eth2 vrf 'blue'
set protocols static route 10.30.0.0/24 interface br10 vrf 'red'

set service ssh disable-host-validation
set service ssh vrf 'mgmt'
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

set system name-server 'eth0'

set vrf name blue protocols static route 10.0.0.0/24 interface eth1 vrf
↪ 'default'
set vrf name blue table '3000'
set vrf name mgmt table '1000'
set vrf name red protocols static route 10.0.0.0/24 interface eth1 vrf 'default
↪ '
set vrf name red table '2000'

```

## VRF and NAT

### Configuration

```

set interfaces ethernet eth0 address '172.16.50.12/24'
set interfaces ethernet eth0 vrf 'red'

set interfaces ethernet eth1 address '192.168.130.100/24'
set interfaces ethernet eth1 vrf 'blue'

set nat destination rule 110 description 'NAT ssh- INSIDE'
set nat destination rule 110 destination port '2022'
set nat destination rule 110 inbound-interface name 'eth0'
set nat destination rule 110 protocol 'tcp'
set nat destination rule 110 translation address '192.168.130.40'

set nat source rule 100 outbound-interface name 'eth0'
set nat source rule 100 protocol 'all'
set nat source rule 100 source address '192.168.130.0/24'
set nat source rule 100 translation address 'masquerade'

set service ssh vrf 'red'

set vrf bind-to-all
set vrf name blue protocols static route 0.0.0.0/0 next-hop 172.16.50.1 vrf
↪ 'red'
set vrf name blue protocols static route 172.16.50.0/24 interface eth0 vrf 'red
↪ '
set vrf name blue table '1010'

set vrf name red protocols static route 0.0.0.0/0 next-hop 172.16.50.1
set vrf name red protocols static route 192.168.130.0/24 interface eth1 vrf
↪ 'blue'
set vrf name red table '2020'

```

## Operation

After committing the configuration we can verify all leaked routes are installed, and try to ICMP ping PC1 from PC3.

```
PCS> ping 10.0.0.1
```

```
84 bytes from 10.0.0.1 icmp_seq=1 ttl=63 time=1.943 ms
84 bytes from 10.0.0.1 icmp_seq=2 ttl=63 time=1.618 ms
84 bytes from 10.0.0.1 icmp_seq=3 ttl=63 time=1.745 ms
```

```
VPCS> show ip
```

```
NAME       : VPCS[1]
IP/MASK     : 10.30.0.1/24
GATEWAY     : 10.30.0.254
DNS         :
MAC         : 00:50:79:66:68:0f
```

## VRF default routing table

```
vyos@R1:~$ show ip route
```

```
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup
```

```
C>* 10.0.0.0/24 is directly connected, eth1, 00:07:44
```

```
S>* 10.20.0.0/24 [1/0] is directly connected, eth2 (vrf blue), weight 1,
↪ 00:07:38
```

```
S>* 10.30.0.0/24 [1/0] is directly connected, br10 (vrf red), weight 1,
↪ 00:07:38
```

## VRF red routing table

```
vyos@R1:~$ show ip route vrf red
```

```
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup
```

```
VRF red:
```

```
K>* 0.0.0.0/0 [255/8192] unreachable (ICMP unreachable), 00:07:57
```

```
S>* 10.0.0.0/24 [1/0] is directly connected, eth1 (vrf default), weight 1,
↪ 00:07:40
```

```
C>* 10.30.0.0/24 is directly connected, br10, 00:07:54
```

## VRF blue routing table

```
vyos@R1:~$ show ip route vrf blue
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued, r - rejected, b - backup

VRF blue:
K>* 0.0.0.0/0 [255/8192] unreachable (ICMP unreachable), 00:08:00
S>* 10.0.0.0/24 [1/0] is directly connected, eth1 (vrf default), weight 1,
->00:07:44
C>* 10.20.0.0/24 is directly connected, eth2, 00:07:53
```

## 8.15 L3VPN VRFs

L3VPN VRFs ( Layer 3 Virtual Private Networks ) bgpd supports for IPv4 RFC 4364 and IPv6 RFC 4659. L3VPN routes, and their associated VRF MPLS labels, can be distributed to VPN SAFI neighbors in the default, i.e., non VRF, BGP instance. VRF MPLS labels are reached using core MPLS labels which are distributed using LDP or BGP labeled unicast. bgpd also supports inter-VRF route leaking.

### 8.15.1 VRF Route Leaking

BGP routes may be leaked (i.e. copied) between a unicast VRF RIB and the VPN SAFI RIB of the default VRF for use in MPLS-based L3VPNs. Unicast routes may also be leaked between any VRFs (including the unicast RIB of the default BGP instance). A shortcut syntax is also available for specifying leaking from one VRF to another VRF using the default instance's VPN RIB as the intermediary . A common application of the VRF-VRF feature is to connect a customer's private routing domain to a provider's VPN service. Leaking is configured from the point of view of an individual VRF: import refers to routes leaked from VPN to a unicast VRF, whereas export refers to routes leaked from a unicast VRF to VPN.

---

**Bemerkung:** Routes exported from a unicast VRF to the VPN RIB must be augmented by two parameters:

an RD / RTLIST

Configuration for these exported routes must, at a minimum, specify these two parameters.

---

### 8.15.2 Configuration

Configuration of route leaking between a unicast VRF RIB and the VPN SAFI RIB of the default VRF is accomplished via commands in the context of a VRF address-family.

```
set vrf name <name> protocols bgp address-family <ipv4-unicast|ipv6-unicast> rd vpn
export <asn:nn|address:nn>
```

Specifies the route distinguisher to be added to a route exported from the current unicast VRF to VPN.

```
set vrf name <name> protocols bgp address-family <ipv4-unicast|ipv6-unicast> route-target
vpn <import|export|both> [RTLIST]
```

Specifies the route-target list to be attached to a route (export) or the route-target list to match against (import) when exporting/importing between the current unicast VRF and VPN. The RTLIST is a space-separated list of route-targets, which are BGP extended community values as described in Extended Communities Attribute.

```
set vrf name <name> protocols bgp address-family <ipv4-unicast|ipv6-unicast> label vpn  
export <0-1048575|auto>
```

Enables an MPLS label to be attached to a route exported from the current unicast VRF to VPN. If the value specified is auto, the label value is automatically assigned from a pool maintained.

```
set vrf name <name> protocols bgp address-family <ipv4-unicast|ipv6-unicast> label vpn  
allocation-mode per-nexthop
```

Select how labels are allocated in the given VRF. By default, the per-vrf mode is selected, and one label is used for all prefixes from the VRF. The per-nexthop will use a unique label for all prefixes that are reachable via the same nexthop.

```
set vrf name <name> protocols bgp address-family <ipv4-unicast|ipv6-unicast> route-map  
vpn <import|export> [route-map <name>]
```

Specifies an optional route-map to be applied to routes imported or exported between the current unicast VRF and VPN.

```
set vrf name <name> protocols bgp address-family <ipv4-unicast|ipv6-unicast>  
<import|export> vpn
```

Enables import or export of routes between the current unicast VRF and VPN.

```
set vrf name <name> protocols bgp address-family <ipv4-unicast|ipv6-unicast> import vrf  
<name>
```

Shortcut syntax for specifying automatic leaking from vrf VRFNAME to the current VRF using the VPN RIB as intermediary. The RD and RT are auto derived and should not be specified explicitly for either the source or destination VRF's.

```
set vrf name <name> protocols bgp interface <interface> mpls forwarding
```

It is possible to permit BGP install VPN prefixes without transport labels. This configuration will install VPN prefixes originated from an e-bgp session, and with the next-hop directly connected.

### 8.15.3 Operation

It is not sufficient to only configure a L3VPN VRFs but L3VPN VRFs must be maintained, too. For L3VPN VRF maintenance the following operational commands are in place.

```
show bgp <ipv4|ipv6> vpn
```

Print active IPV4 or IPV6 routes advertised via the VPN SAFI.

```
BGP table version is 2, local router ID is 10.0.1.1, vrf id 0
Default local pref 100, local AS 65001
Status codes: s suppressed, d damped, h history, * valid, > best, = multipath,
               i internal, r RIB-failure, S Stale, R Removed
Nexthop codes: @NNN nexthop's vrf id, < announce-nh-self
Origin codes: i - IGP, e - EGP, ? - incomplete
```

Network	Next Hop	Metric	LocPrf	Weight	Path
Route Distinguisher: 10.50.50.1:1011					
*>i10.50.50.0/24	10.0.0.7	0	100	0	i

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
UN=10.0.0.7 EC{65035:1011} label=80 type=bgp, subtype=0
Route Distinguisher: 10.60.60.1:1011
*>i10.60.60.0/24 10.0.0.10 0 100 0 i
UN=10.0.0.10 EC{65035:1011} label=80 type=bgp, subtype=0
```

### show bgp <ipv4|ipv6> vpn summary

Print a summary of neighbor connections for the specified AFI/SAFI combination.

```
BGP router identifier 10.0.1.1, local AS number 65001 vrf-id 0
BGP table version 0
RIB entries 9, using 1728 bytes of memory
Peers 4, using 85 KiB of memory
Peer groups 1, using 64 bytes of memory
```

10.0.0.7	4	65001	2860	2870	0	0	0	1d23h34m	↵
→ 2	10								

### 9.1 Information

VyOS features a rich set of operational level commands to retrieve arbitrary information about your running system.

#### 9.1.1 Hardware

##### USB

In the past serial interface have been defined as ttySx and ttyUSBx where x was an instance number of the serial interface. It was discovered that from system boot to system boot the mapping of USB based serial interfaces will differ, depending which driver was loaded first by the operating system. This will become rather painful if you not only have serial interfaces for a console server connected but in addition also a serial backed *WWAN - Wireless Wide-Area-Network*.

To overcome this issue and the fact that in almost 50% of all cheap USB to serial converters there is no serial number programmed, the USB to serial interface is now directly identified by the USB root bridge and bus it connects to. This somehow mimics the new network interface definitions we see in recent Linux distributions.

For additional details you can refer to <https://vyos.dev/T2490>.

##### **show hardware usb**

Retrieve a tree like representation of all connected USB devices.

---

**Bemerkung:** If a device is unplugged and re-plugged it will receive a new Port, Dev, If identification.

---

```
vyos@vyos:~$ show hardware usb
/: Bus 03.Port 1: Dev 1, Class=root_hub, Driver=ehci-pci/2p, 480M
  |__ Port 1: Dev 2, If 0, Class=Hub, Driver=hub/4p, 480M
    |__ Port 3: Dev 4, If 0, Class=Vendor Specific Class, Driver=qcserial, 480M
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

    |__ Port 3: Dev 4, If 2, Class=Vendor Specific Class, Driver=qcserial, 480M
    |__ Port 3: Dev 4, If 3, Class=Vendor Specific Class, Driver=qcserial, 480M

## 9.1.2 Version

### show version

Return the current running VyOS version and build information. This includes also the name of the release train which is *crux* on VyOS 1.2, *equuleus* on VyOS 1.3 and *sagitta* on VyOS 1.4.

```
vyos@vyos:~$ show version

Version:          VyOS 1.4-rolling-202106270801
Release Train:    sagitta

Built by:         autobuild@vyos.net
Built on:         Sun 27 Jun 2021 09:50 UTC
Build UUID:       ab43e735-edcb-405a-9f51-f16a1b104e52
Build Commit ID:  f544d75eab758f

Architecture:     x86_64
Boot via:         installed image
System type:      KVM guest

Hardware vendor:   QEMU
Hardware model:    Standard PC (i440FX + PIIX, 1996)
Hardware S/N:      Unknown
Hardware UUID:     Unknown

Copyright:        VyOS maintainers and contributors
```

### show version kernel

Return version number of the Linux Kernel used in this release.

```
vyos@vyos:~$ show version kernel
5.10.46-amd64-vyos
```

### show version frr

Return version number of FRR (Free Range Routing - <https://frrouting.org/>) used in this release. This is the routing control plane and a successor to GNU Zebra and Quagga.

```
vyos@vyos:~$ show version frr
FRRouting 7.5.1-20210625-00-gf07d935a2 (vyos).
Copyright 1996-2005 Kunihiko Ishiguro, et al.
```

## 9.2 Boot Options

**Warnung:** This function may be highly disruptive. It may cause major service interruption, so make sure you really need it and verify your input carefully.

VyOS has several kernel command line options to modify the normal boot process. To add an option, select the desired image in GRUB menu at load time, press **e**, edit the first line, and press **Ctrl-x** to boot when ready.

```

GNU GRUB  version 2.02~beta2-22+deb8u1

+-----+
|setparams 'VyOS 1.2.6-epal linux (Serial console)'

```

### 9.2.1 Specify custom config file

Tells the system to use specified file instead of `/config/config.boot`. If specified file does not exist or is not readable, fall back to default config. No additional verification is performed, so make sure you specify a valid config file.

```
vyos-config=/path/to/file
```

To load the *factory default* config, use:

```
vyos-config=/opt/vyatta/etc/config.boot.default
```

### 9.2.2 Disable specific boot process steps

These options disable some boot steps. Make sure you understand the *boot process* well before using them!

#### **no-vyos-migrate**

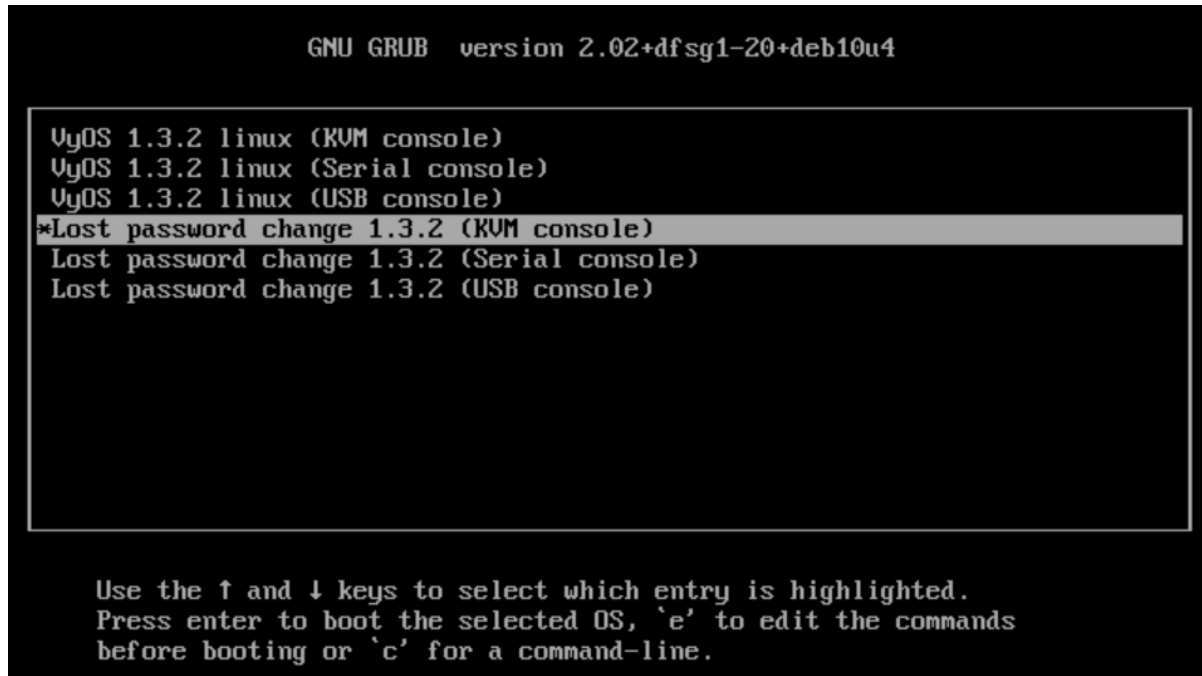

Do not perform config migration.

#### **no-vyos-firewall**

Do not initialize default firewall chains, renders any firewall configuration unusable.

## 9.3 Password Recovery

Using the console, restart the VyOS router. The GRUB menu appears. Select the relevant option from the GRUB menu and press Enter. The option must start with “Lost password change.”

```

GNU GRUB  version 2.02+dfsg1-20+deb10u4

VyOS 1.3.2 linux (KVM console)
VyOS 1.3.2 linux (Serial console)
VyOS 1.3.2 linux (USB console)
*Lost password change 1.3.2 (KVM console)
Lost password change 1.3.2 (Serial console)
Lost password change 1.3.2 (USB console)

Use the ↑ and ↓ keys to select which entry is highlighted.
Press enter to boot the selected OS, 'e' to edit the commands
before booting or 'c' for a command-line.

```

The stand-alone user-password recovery tool starts running and prompts you to reset the local system user password.

```

Do you wish to reset the admin password? (y or n)
y
Which admin account do you want to reset?[vyos]
my_username
Enter my_username password:
Retype my_username password:
System will reboot in 10 seconds...

```

## 9.4 RAID-1

A Redundant Array of Independent Disks (RAID) uses two or more hard disk drives to improve disk speed, store more data, and/or provide fault tolerance. There are several storage schemes possible in a RAID array, each offering a different combination of storage, reliability, and/or performance. The VyOS system supports a “RAID 1” deployment. RAID 1 allows two or more disks to mirror one another to provide system fault tolerance. In a RAID 1 solution, every sector of one disk is duplicated onto every sector of all disks in the array. Provided even one disk in the RAID 1 set is operational, the system continues to run, even through disk replacement (provided that the hardware supports in-service replacement of drives). RAID 1 can be implemented using special hardware or it can be implemented in software. The VyOS system supports software RAID 1 on two disks. The VyOS implementation of RAID 1 allows the following:

- Detection and reporting of disk failure
- The ability to maintain system operation with one failed disk
- The ability to boot the system with one failed disk

- The ability to replace a failed disk and initiate re-mirroring
- The ability to monitor the status of remirroring

### 9.4.1 Installation Implications

The VyOS systems installation utility provides several options for installing to a RAID 1 set. You can:

- Use the install system to create the RAID 1 set
- Use the underlying Linux commands to create a RAID 1 set before running the install system command.
- Use a previously-created RAID 1 set.

---

**Bemerkung:** Before a permanent installation, VyOS runs a live installation

---

### 9.4.2 Configuration

#### Single disk, install as normal

When the VyOS system is installed, it automatically detects the presence of two disks not currently part of a RAID array. In these cases, the VyOS installation utility automatically offers you the option of configuring RAID 1 mirroring for the drives, with the following prompt.

Would you like to configure RAID 1 mirroring on them?

- If you do not want to configure RAID 1 mirroring, enter “No” at the prompt and continue with installation in the normal way.

#### Empty 2+ Disk

If VyOS system detect two identical disks that are not currently part of a RAID-1 set, the VyOS installation utility automatically offers you the option of configuring RAID 1 mirroring for the drives, with the following prompt.

Would you like to configure RAID 1 mirroring on them?

1 - To create a new RAID 1 array, enter “Yes” at the prompt. If the system detects a filesystem on the partitions being used for RAID 1 it will prompt you to indicate whether you want to continue creating the RAID 1 array.

Continue creating array?

2 - To overwrite the old filesystem, enter “Yes”.

3 - The system informs you that all data on both drives will be erased. You are prompted to confirm that you want to continue

Are you sure you want to do this?

4 - Enter “Yes” at the prompt to retain the current VyOS configuration once installation is complete. Enter “No” to delete the current VyOS configuration.

Would you like me to save the data on it before I delete it?

5 - Enter “Yes” at the prompt to retain the current VyOS configuration once installation is complete. Enter “No” to delete the current VyOS configuration.

6 - Continue with installation in the normal way.

## Present RAID-1

When the VyOS software on a system with a RAID 1 set already configured, the installation utility will detect the array and will display the following prompt:

```
Would you like to use this one?
```

1 - To break apart the current RAID 1 set, enter “No” at the prompt. The

installation utility detects that there are two identical disks and offers you the option of configuring RAID 1 mirroring on them, displaying the following prompt:

```
Would you like to configure RAID 1 mirroring on them?
```

2 - To decline to set up a new RAID 1 configuration on the disks, enter “No” at the prompt. The system prompts you to indicate which partition you would like the system installed on.

```
Which partition should I install the root on? [sda1]:
```

3 - Enter the partition where you would like the system installed. The system then prompts you to indicate whether you want to save the old configuration data. This represents the current VyOS configuration.

```
Would you like me to save the data on it before I delete it?
```

4 - Enter “Yes” at the prompt to retain the current VyOS configuration once installation is complete. Enter “No” to delete the current VyOS configuration.

5 - Continue with installation in the normal way.

## Detecting and Replacing a Failed RAID 1 Disk

The VyOS system automatically detects a disk failure within a RAID 1 set and reports it to the system console. You can verify the failure by issuing the `show raid` command.

To replace a bad disk within a RAID 1 set, perform the following steps:

1 - Remove the failed disk from the RAID 1 set by issuing the following command:

```
delete raid <RAID-1-device> member <disk-partition>
```

where RAID-1-device is the name of the RAID 1 device (for example, md0) and disk-partition is the name of the failed disk partition (for example, sdb2).

2 - Physically remove the failed disk from the system. If the drives are not hot-swappable, then you must shut down the system before removing the disk.

3 - Replace the failed drive with a drive of the same size or larger.

4 - Format the new disk for RAID 1 by issuing the following command:

```
format disk <disk-device1> like <disk-device2>
```

where disk-device1 is the replacement disk (for example, sdb) and disk-device2 is the existing healthy disk (for example, sda).

5-Add the replacement disk to the RAID 1 set by issuing the following command:

```
add raid <RAID-1-device> member <disk-partition>
```

where RAID-1-device is the name of the RAID 1 device (for example, md0) and disk-partition is the name of the replacement disk partition (for example, sdb2).

### 9.4.3 Operation

This part introduces how to add a disk partition to a RAID-1 set initiates mirror synchronization, check and display information.

```
add raid <RAID-1-device> member <disk-partition>
```

Use this command to add a member disk partition to the RAID 1 set. Adding a disk partition to a RAID 1 set initiates mirror synchronization, where all data on the existing member partition is copied to the new partition.

```
format disk <disk-device1> like <disk-device2>
```

This command is typically used to prepare a disk to be added to a preexisting RAID 1 set (of which disk-device2 is already a member).

```
show raid <RAID-1-device>
```

shows output for show raid md0 as sdb1 is being added to the RAID 1 set and is in the process of being resynchronized.

```
vyos@vyos:~$ show raid md0
/dev/md0:
  Version : 00.90
Creation Time : Wed Oct 29 09:19:09 2008
  Raid Level : raid1
  Array Size : 1044800 (1020.48 MiB 1069.88 MB)
Used Dev Size : 1044800 (1020.48 MiB 1069.88 MB)
  Raid Devices : 2
Total Devices : 2
Preferred Minor : 0
  Persistence : Superblock is persistent
Update Time : Wed Oct 29 19:34:23 2008
  State : active, degraded, recovering
Active Devices : 1
Working Devices : 2
Failed Devices : 0
Spare Devices : 1
Rebuild Status : 17% complete
  UUID : 981abd77:9f8c8dd8:fdbf4de4:3436c70f
  Events : 0.103
  Number Major Minor RaidDevice State
    0      8      1        0 active sync /dev/sda1
    2      8     17        1 spare rebuilding /dev/sdb1
```

```
show raid <RAID-1-device>
```

Use this command to display the formatting of a hard disk.

```
vyos@vyos:~$ show disk sda format
Disk /dev/sda: 1073 MB, 1073741824 bytes
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```
85 heads, 9 sectors/track, 2741 cylinders
Units = cylinders of 765 * 512 = 391680 bytes
Disk identifier: 0x000b7179
Device Boot      Start         End      Blocks   Id  System
/dev/sda1          6         2737     1044922+  fd  Linux raid autodetect
```

### 10.1 VyOS API

For configuration and enabling the API see [HTTP API](#)

#### 10.1.1 Authentication

All endpoints only listen on HTTP POST requests and the API KEY must set as **key** in the formdata.

Below see one example for curl and one for python. The rest of the documentation is reduced to curl.

```
curl --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "showConfig", "path": []}' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'
```

```
import requests
url = "https://vyos/retrieve"
payload={'data': '{"op": "showConfig", "path": []}',
        'key': 'MY-HTTPS-API-PLAINTEXT-KEY'
        }
headers = {}
response = requests.request("POST", url, headers=headers, data=payload)
print(response.text)
```

## 10.1.2 API Endpoints

### /retrieve

With the retrieve endpoint you get parts or the whole configuration.

To get the whole configuration, pass an empty list to the path field

```
curl --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "showConfig", "path": [] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'
```

```
response (shorted)
{
  "success": true,
  "data": {
    "interfaces": {
      "ethernet": {
        "eth0": {
          "address": "dhcp",
          "duplex": "auto",
          "hw-id": "50:00:00:01:00:00",
          "speed": "auto"
        },
        "eth1": {
          "duplex": "auto",
          "hw-id": "50:00:00:01:00:01",
          "speed": "auto"
        },
        ...
      },
      "error": null
    }
  }
```

To only get a part of the configuration, for example `system syslog`.

```
curl -k --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "showConfig", "path": ["system", "syslog"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'
```

```
response:
{
  "success": true,
  "data": {
    "global": {
      "facility": {
        "all": {
          "level": "info"
        },
        "protocols": {
          "level": "debug"
        }
      }
    }
  }
```

(Fortsetzung auf der nächsten Seite)

(Fortsetzung der vorherigen Seite)

```

    }
  },
  "error": null
}

```

if you just want the Value of a multi-valued node, use the `returnValues` operation.

For example, get the addresses of a `dum0` interface.

```

curl -k --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "returnValues", "path": ["interfaces","dummy","dum0","address"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": [
    "10.10.10.10/24",
    "10.10.10.11/24",
    "10.10.10.12/24"
  ],
  "error": null
}

```

To check existence of a configuration path, use the `exists` operation.

For example, check an existing path:

```

curl -k --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "exists", "path": ["service","https","api"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": true,
  "error": null
}

```

versus a non-existent path:

```

curl -k --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "exists", "path": ["service","non","existent","path"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": false,
  "error": null
}

```

## /reset

The reset endpoint run a reset command.

```
curl --location --request POST 'https://vyos/reset' \
--form data='{ "op": "reset", "path": ["ip", "bgp", "192.0.2.11"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": "",
  "error": null
}
```

## /reboot

To initiate a reboot use the reboot endpoint.

```
